We have not spoken here of gaseous poisons, which would lead to unnecessary details. They act either by excluding the common atmospheric air, in which case removal into pure air is required; or by producing inflammation, like the irritant, or oppression of the brain, like the narcotic poisons, and are to be combated on similar principles. It will be more useful to append a list of the poisons which act on the brain, and of those which act on the heart. Of poisons which act upon the brain the most common are alcohol, that is spirituous liquors, opium, henbane, hemlock, camphor, and the essential oil of almonds, and of tobacco. Of those acting on the heart, the chief are, infusion of tobacco, and large doses of prussic acid, foxglove, strychnia (principle of nux vomica), oxalic acid, arsenic, preparations or salts of antimony and of baryta, chloroform, and several animal poisons.

From what has been said on this subject, the great necessity of an acquaintance with it must be sufficiently clear, not only to insure our doing right, but to prevent us from doing wrong. By administering an ill-timed antidote (as we conceive it to be), we often hasten the fatal event: as where vinegar is given when opium has been swallowed, before it has been ejected from the stomach; and by throwing tobacco smoke into the bowels of a person apparently drowned, we extinguish the feeble spark of life which might have sufficed to re-animate him but for such injudicious interference.

It is to be hoped that more just principles of treatment will be diffused among the people, as well as among medical men, by which many lives may be preserved to their families and to the community. [POISONS.]

ANTI-FERMENT. In the cider-districts a substance under this name is sold for the purpose of correcting fermentation. Mustard seed and clover, or mustard seed and sulphate of lime, are usually the ingredients: they tend to allay the fermentation of cider or perry, or even beer.

ANTI-FRICTION WHEELS. The action of friction or anti-friction wheels in machinery is to diminish resistance by converting what would otherwise be a rubbing into a rolling contact. Friction rollers, which are generally of small diameter, are not necessarily fixed upon axles or shafts, but are interposed bodily between the rubbing or sliding surfaces which press upon them; and they may thus be employed to alleviate friction between surfaces. In some arrangements of mechanism, friction rollers are provided with small axles which do not bear any important strain, but are used chiefly for the purpose of keeping the rollers in their proper place. The wheels of an ordinary carriage are in principle very little other than anti-friction wheels or rollers.

The various applications of anti-friction rotation are very numerous; but they all depend on this principle—that when the surfaces of two bodies are made to pass over each other with a rubbing or sliding motion, their inequalities necessarily meet and oppose each other, and thereby cause both resistance and wear; but if rollers or wheels be applied between them, instead of the inequalities of the roller being dragged against those of the surface upon which it rolls, they are successively laid upon (so to speak) and lifted up from them.

ANTILOGARITHM, as used in this country, means the *number to the logarithm*. Thus, in Brigg's system, 100 is the antilogarithm of 2, because 2 is the logarithm of 100. We have introduced this term, because the French 'Encyclopædia,' followed by Dr. Hutton, have defined the word to mean what is more usually called the *complement* of the logarithm, namely, the remainder produced by subtracting the logarithm from the next higher term in the series, 1, 10, 100, &c. This is not the most commonly received meaning of the word in this country.

It is becoming usual to express the number to a logarithm by writing the logarithm in brackets. There is, however, another notation much more consistent with received symbols. In the same manner as $\sin^{-1}x$ stands for the *angle whose sine is* x, $\log^{-1}x$ should mean the *number whose logarithm is* x. Thus, we might write either

$$\log 100 = 2$$
$$\text{or } 100 = \log^{-1} 2.$$

ANTIMONIC ACID. [ANTIMONY.]

ANTIMONIOUS ACID. [ANTIMONY.]

ANTIMONY (Sb), a metal, sometimes called *regulus of antimony*, to distinguish it from *crude antimony*, the name by which the native sulphuret is known in commerce. The ores of antimony have long been known, but Basil Valentine first obtained it in the metallic state towards the end of the 15th century. It occurs, though rarely, native, but is generally obtained from the sulphuret, which is by far its most abundant ore. The sulphuret is roasted in reverberatory furnaces, by which it is converted into a compound of oxide and sulphuret of antimony, known as *glass of antimony*; this is then mixed with charcoal impregnated with carbonate of soda, and heated in crucibles; and the oxide is reduced to the metallic state by the carbon, then the sulphuret is converted into oxide by the carbonate of soda. As it occurs in commerce the metal contains lead, iron, sulphur, and arsenic, from which it may be freed by fusion with 10 per cent. of nitre.

Antimony has a silver white colour, of great lustre, and a fracture varying from broad laminated to granular crystalline, according to the rapidity with which it has been cooled; it crystallises mostly in acute rhombohedrons. It is very brittle, and easily powdered. Its sp. gr. varies from 6·70 to 6·86; it fuses at 778° F., and does not expand on cooling. At a white heat it can be distilled in an atmosphere of hydrogen. It does not sensibly alter in the air at ordinary temperatures, but readily oxidises when melted in contact with air. Its symbol is Sb (*stibium*), and its atomic weight 120·3 (Scheeren). In its chemical relations it is closely allied to nitrogen, phosphorus, and arsenic.

Oxide of Antimony—Antimonic Oxide (SbO_3) occurs native as white antimony ore. When antimony is heated in an imperfectly closed crucible, this substance is deposited on the sides in the form of brilliant white prismatic crystals, which have been called *argentine flowers of antimony*. Thus prepared it often contains antimoniate of oxide of antimony; and the purest oxide is obtained by digesting oxychloride of antimony with a solution of carbonate of soda, and carefully washing and drying the residue.

Oxide of antimony is of a grayish colour. Heated in contact with the air it is resolved into antimoniate of oxide of antimony, it is insoluble in water, but is dissolved by dilute nitric and hydrochloric acids, and by strong nitric acid is oxidised to antimonic acid. It is a feeble base, and unites with acids to form salts of oxide of antimony, which have a weak metallic taste, and act as emetics. The most important of these, and indeed the most important compound of antimony, *tartar emetic*, $SbO_3, KO, C_8H_4O_{10}, 2HO$, is a combination of tartaric acid with potash and oxide of antimony. It is prepared by boiling oxide of antimony, or glass of antimony, with cream of tartar; the solution filtered hot, deposits on cooling white brilliant octohedra, which are the salt in question. The neutral salts of antimonic oxide are decomposed by excess of water into a free acid, which retains some of the oxide in solution, and into a basic salt which precipitates. The addition of tartaric acid prevents this precipitation. Sulphuretted hydrogen produces in acid solutions of teroxide of antimony, an orange-coloured precipitate of tersulphide of antimony soluble in potash, and sulphide of ammonium.

Antimonic Acid (SbO_5) is prepared by dissolving antimony in aqua regia, evaporating to dryness, and calcining the residue at a temperature below redness. Thus obtained it is anhydrous, and is a white powder, which when strongly heated gives off oxygen, and is converted into an intermediate oxide, SbO_4. It is also insoluble in water, but when boiled with alkalies or alkaline carbonates, it gradually dissolves, and from this solution acids precipitate the hydrated antimonic acid, SbO_5, HO. It is a monobasic acid, and the general formula of the antimoniates in the anhydrous condition is MO, SbO_5. Antimonic acid is also obtained when pentachloride of antimony is decomposed by excess of water;

$$\underbrace{SbCl_5}_{\text{Pentachloride of Antimony.}} + \underbrace{7HO}_{\text{Water.}} = \underbrace{SbO_5, 2HO}_{\text{Metantimonic Acid.}} + \underbrace{5HCl}_{\text{Hydrochloric Acid.}}$$

But the acid thus prepared differs from the former one in being bibasic. It forms salts which have the general formula, $2MO, SbO_5$, and MO, HO, SbO_5: it is called *metantimonic acid*, and its salts *metantimoniates*.

Antimoniate of antimonic oxide ($SbO_4 = SbO_3, SbO_5$), or *antimonious acid*, is formed when either of the two oxides is heated in the air. It is a grayish white, infusible, non-volatile powder, insoluble in water. When treated with tartaric acid, teroxide of antimony is dissolved, and antimonic acid left; while treatment with alkalies removes antimonic acid and leaves antimonic oxide.

Antimony forms with chlorine two compounds, the terchloride and the pentachloride.

Terchloride of antimony ($SbCl_3$) may be prepared by mixing one part of metallic antimony with two parts of chloride of mercury, and submitting the mixture to distillation in a retort. The chloride distils over as a buttery mass, which becomes crystalline in solidifying. From its appearance the term *butter of antimony* is derived; the substance occurring in commerce under this name is a more or less concentrated solution of the terchloride in hydrochloric acid, and is usually prepared by treating native sulphuret of antimony with strong hydrochloric acid.

$$\underbrace{SbS_3}_{\text{Sulphuret of Antimony.}} + \underbrace{3HCl}_{\text{Hydrochloric Acid.}} = \underbrace{SbCl_3}_{\text{Terchloride of Antimony.}} + \underbrace{3SH}_{\text{Sulphuretted Hydrogen.}}$$

It is used as a caustic in veterinary surgery, and is also employed for bronzing gun-barrels; in which latter case it acts by the deposition of a thin film of antimony, which protects the barrel from oxidation.

Terchloride of antimony is very deliquescent; when treated with a small quantity of water it dissolves, but on the addition of a larger quantity, a white flocculent precipitate is formed, which changes after some time to a crystalline powder. This is the *powder of algaroth*, an antimonial preparation, formerly of great importance; it is a compound of teroxide of antimony with chloride of antimony, its formula being $SbCl_3 + 5SbO_3$. The flocculent precipitate which at first forms is considered to be an oxychloride, SbO_2Cl.

Pentachloride of antimony ($SbCl_5$) is prepared by distilling antimony in a current of chlorine; the combination is effected with disengagement of heat, and the pentachloride distils over as a mobile, pale yellow liquid, which emits white fumes in the air, and has a strong disagreeable smell. It attracts moisture from the atmosphere, and, by a larger quantity of water, is decomposed into antimonic and hydrochloric acids. Pentachloride of antimony readily gives up part of its chlorine; on passing olefiant gas through it, chloride of ethylene ($C_4H_4Cl_2$), Dutch liquid, is formed, and phosgene gas ($C_2O_2Cl_2$) is produced when carbonic oxide (CO) is conducted into it. With dry sulphuretted hydrogen it forms a white crystalline compound, the sulphochloride of antimony (SbS_2Cl_3), analogous to the sulphochloride of phosphorus.

Bromine and iodine form with antimony respectively the *terbromide* and *teriodide of antimony* ($SbBr_3$, and SbI_3).

Antimony forms with sulphur two sulphides of antimony (SbS_3 and SbS_5), corresponding to antimonic oxide and antimonic acid. The tersulphide occurs native; it is of a leaden gray colour, with radiating crystalline fracture and metallic aspect. When heated in closed vessels it melts and crystallises in striated masses. It may be prepared by heating together antimony and sulphur. When heated in the air it absorbs oxygen, and becomes converted into oxide of antimony, which combines with undecomposed sulphuret in proportions which vary with the duration of the experiment and the temperature employed. These oxysulphides are known as *glass of antimony*, or *crocus*, or *liver of antimony*. Native tersulphide of antimony is used as an ingredient in Bengal fire.

Tersulphide of antimony (SbS_3) is formed as a characteristic orange-red precipitate, when sulphuretted hydrogen is passed through an acid solution of antimonic oxide. It dissolves readily in alkalies and alkaline sulphides, and is again precipitated by acids.

Kermes mineral, a preparation occasionally used in medicine, consists essentially of the hydrated tersulphide mixed or combined with teroxide of antimony and sometimes sulphantimonic acid. It may be prepared in the moist way by boiling native tersulphide of antimony in fine powder with solution of carbonate of soda; the solution deposits, on cooling, the kermes as a red amorphous powder.

Pentasulphide of antimony (SbS_5), or *sulphantimonic acid*, is formed when sulphuretted hydrogen gas is passed through solution of pentachloride of antimony. It is a yellowish red precipitate, which readily dissolves in alkalies and in alkaline sulphides; with the latter it forms sulphur salts, which frequently crystallise well. A *sulphantimoniate of sulphide of sodium*, occasionally used in medicine, forms pale yellow crystals, which have the formula $3NaS, SbS_5 + 18HO$.

Antimoniuretted hydrogen (SbH_3). When an alloy of zinc and antimony is treated with dilute sulphuric acid, or when a solution of teroxide of antimony is added to dilute sulphuric acid and zinc, the gas disengaged consists of hydrogen containing a small proportion of antimoniuretted hydrogen. The gas has an alliaceous odour, and imparts to the flame of the hydrogen a livid white appearance. When passed through a heated narrow tube, or when its flame impinges on a cold porcelain plate, a mirror of reduced antimony is deposited. The gas has not been obtained pure, but its composition is most probably SbH_3. It is analogous to ammonia and phosphuretted hydrogen.

When antimony is alloyed with other metals, it generally renders them harder and more brittle. By far the most important alloy is that of antimony and lead, which forms *type metal*; it contains 17 to 20 per cent. of antimony. This alloy expands at the moment of solidification, and takes a very sharp impression of the mould.

Mr. Gore has recently found, that when antimony is electrolytically deposited from a solution of three or four parts of tartar emetic in one part of butter of antimony, it possesses most singular properties. By friction, by scratching, or by feeble percussion, it is reduced to powder, with a sufficient disengagement of heat to melt tin, and a sort of explosion accompanied by the emission of white vapours. The same phenomena take place when it is immersed in water of 75° C., which is then found to contain hydrochloric acid and oxychloride of antimony.

The compounds of antimony are recognised by the characteristic colour of the precipitates produced by sulphuretted hydrogen in their solutions.

ANTIMONY (MEDICAL USES OF). Though the introduction of antimony into the number of medicinal agents was very violently opposed, and even decrees by the Parliament of Paris were passed against its use, it is now justly regarded as a most valuable remedy in many diseases. As antimony cannot produce any effect on the human system, unless when so prepared as to be capable of decomposition by the fluids of the body, the tartarised form, being the most soluble, has properly superseded the others. Its action varies according to the dose, the mode of administration, and the state of the system when it is exhibited. In very small doses, it seems to increase the activity of the function of secretion, particularly of the mucous membranes; hence it occasions a flow of thin fluid from these surfaces, which form the inner lining of the lungs and intestinal canal; and also an increased action of the skin, and flow of perspiration, if the patient be kept warm. In a larger dose it causes vomiting, with all the phenomena of that action; and from being commonly employed for this purpose, it is designated *Emetic Tartar.* Compared with other emetics it may be said to be distinguished by the ease with which it causes vomiting, as well as by the certainty, though in this latter respect it is surpassed by sulphate of zinc (white vitriol). It may be given to persons of any age, except to very young children, for whom ipecacuanha wine is preferable. It ought not to be given in cases of poisoning, for reasons stated under the head ANTIDOTES, and least of all should it be given in cases of narcotic poisons, since in large doses it is itself a poison, unless vomiting take place; and as, by narcotic poisons, the sensibility of the stomach is so lowered or destroyed as not to occasion the rejection of anything received into it, the impropriety of exhibiting tartar emetic in such cases is manifest. From the extremely small quantity of this substance which is sufficient to occasion vomiting, there is one state in which it is to be preferred to every other means of causing vomiting. By whatever channel tartar emetic is introduced into the system, it invariably excites the stomach to perform the act of vomiting, unless the person be in a state of insensibility or coma; a solution of two grains of it, in three ounces of warm distilled water, may, by a skilful operator, be injected into a vein when the gullet is obstructed by any extraneous body lodged in it. In the same way it may be sometimes tried in tetanus, or lock-jaw, when the teeth are so firmly clenched together that nothing can be made to pass them.

As tartarised antimony is decomposed by most bitter or astringent vegetables, which contain tannin (except oak-bark), and an insoluble, and consequently an inert, tannate of the protoxide of antimony is thereby produced, such vegetables, in the form of infusion, decoction, or tincture, furnish the best antidote in cases of over-dose, or poisoning by this article, should it not, by inducing vomiting, prove its own antidote. Under these circumstances, we should administer decoction or tincture of yellow cinchona bark, or, when these cannot be easily procured, a strong infusion of tea.

Employed in appropriate doses, its action as an emetic is seldom violent, while it certainly acts more powerfully than other emetics in prompting the secretion of the fluids of the stomach, as well as of the bile and pancreatic juice, with those of the lungs, and indeed all the secretions, external as well as internal. Now, as the suppression of the secretions is one of the most common occurrences in the early stage of fever, and the restoration and improved character of these one of the most favourable signs of its abatement, antimony is employed with great advantage in the treatment of fever, and it cannot be used too early. Indeed, many a fever is stopped or prevented by the employment of this or some other emetic, as ipecacuanha, upon the first intimation of the disease being felt. It is also suited to the beginning of each paroxysm of intermittent or remittent fevers [AGUE]. It may also be advantageously given about the period of the expected crisis in continued fever. When the disease is of a highly inflammatory type, it should be combined with, or followed by, saline medicines; but when there is great depression of the vital powers, as in typhus, the salines must be soon laid aside, and stimulating medicines cautiously substituted.

Antimony is also used in some eruptive or exanthematous fevers, such as measles and scarlet fever, being less suited for those in which the eruption is of a vesicular or pustular character, and which affect the deeper layers of the skin. (For a classification of cutaneous diseases on this principle, see Craigie's 'Pathological Anatomy.') Antimony is well suited for rheumatic fever and erysipelas, as in these diseases the liver is deranged, and furnishes an unhealthy biliary secretion. It is also useful in what are sometimes termed mucous and bilious fevers, which are attended with very depraved secretions from the intestinal canal, which may be removed and improved by repeated small doses of an antimonial.

It is also in daily use for the cure of catarrhal affections, that is, colds affecting the mucous membrane of the lungs.

Tartrate of antimony, when intended to act as an emetic, is generally given in the dose of a quarter or half a grain dissolved in distilled water, and repeated every ten or twenty minutes till vomiting occurs; but when merely intended to cause nausea, or to act gently on the secretions of the intestinal canal of the lungs or that of the skin, it is given in even smaller doses, and at the interval of two, four, or six hours. Lately, however, a mode of employing it in much larger and more frequent doses has been practised with marked benefit in several diseases of an inflammatory character, particularly in pneumonia or inflammation of the lungs. According to this plan, from two to three grains dissolved in water, are given, and repeated every two hours or so, for a considerable time, even for two or three days. The early doses cause vomiting and purging, but these effects soon cease to appear, while the pulse is found to have fallen to fifty beats, or even less, in a minute. When pursued with caution and managed skilfully, it often enables us to overcome the disease, and to dispense with the removal of so much blood from the system, as might otherwise have been necessary. It ought not to be tried, however, if the mucous membrane of the stomach be in a state of irritation or subacute inflammation; a condition which often occurs during pneumonia. This state of the stomach must be removed by general or local means before we venture upon the exhibition of the antimony.

This plan of administering tartar emetic is generally believed to have originated with the Italian physicians Rasori and Tommasini; but whatever merit it possesses is justly due to Dr. Marryat of Bristol, who proposed it in 1790, many years before its employment in Italy.

Tartrate of antimony is applied externally as an ointment and plaster; and in either way it excites an action of the part, leading to the formation of a vesicular eruption, similar to that of vaccinia or cow-pox; and it is consequently used as a means of counter-irritation, often with great advantage. The ointment and plaster may be prepared of different degrees of strength, but care must be taken not to make them too strong, as the antimony may be absorbed from the ulcerated surface, and produce violent vomiting, which in some cases has been so serious as to cause death.

Other forms or preparations of antimony are used, but more as ingredients of certain compounds than in their simple state. Oxide, more properly teroxide of antimony, called also *flowers of antimony*, is the chief active ingredient in the pulvis antimonialis composition, the officinal substitute for the empirical article called James's powder. This possesses the same diaphoretic, expectorant, and emetic properties as tartarised antimony. It is also the active ingredient in the oxy- or gray sulphuret, the glass of antimony, kermes, and golden sulphuret.

Terchloride (formerly muriate) of antimony, called popularly *butter of antimony*, is a powerful caustic. When applied to the skin, it spreads, cauterising wherever it goes. Proper steps must be taken to limit it to the part to be destroyed. If at hand, it is good to apply instantly to the bite of serpents or mad-dogs.

Oxysulphuret, or precipitated, or golden, sulphuret is the chief active ingredient in the compound chloride of mercury pill, formerly called Plummer's pill. This is of great service in cutaneous diseases as an alterative.

ANTIMONY, OXIDE OF. [ANTIMONY.]

ANTINO'MIANS, from the Greek, signifies *against the law.* It is applied by theologians to those, if any there be, who hold that faith in Jesus Christ dispenses with, and renders unnecessary, so far as a future state is concerned, the observance of morality and the performance of good works. We say, if any there be, because there is reason to suppose that the accounts of earlier antinomians contain much exaggeration, and that there never was any body of men, worthy to be called a sect by numbers and duration, which professed the above opinion.

So far as avowed abandonment of morals, we find various antinomian sects in the first three centuries; but the name was first applied to the followers of John Agricola, a townsman and contemporary of Luther, born at Eisleben in Saxony. His opinions had the tendency above mentioned, and were attacked by Luther, who, with the assistance of the elector of Brandenburg, obliged him to publish a retractation. It must, however, be observed, that Bayle points out (in the article *Islebiens*) the exaggerations which have been made of Agricola's opinions and their source, and that Agricola himself was employed with others in drawing up the 'Interim,' a provisional confession of faith, promulgated by the emperor Charles V., at Augsburg, in 1548, which Dupin (and Catholic writers are, in general, shrewd judges between one Protestant and another), admits to be perfectly orthodox on the article of justification.

This sect has obtained very little notice from Continental writers, and its followers appear rather to have been distributed among other persuasions. The assembly of divines in 1643 condemned several writings which appeared to them antinomian; and the Parliament in 1648, in what ought to be called the Presbyterian persecution Act, among other provisions, enacted, that any one convicted, on the oaths of two witnesses, of maintaining that the moral law of the Ten Commandments is no rule for Christians, or that a believer need not repent or pray for pardon of sin, should publicly retract, or, on his refusal, be imprisoned till he found sureties that he would no more maintain the same.

The little importance of this sect renders it unnecessary to dwell further upon its history; but the name, like others, is bandied about as a term of reproach by many who do not understand its meaning.

ANTINOUS. [AQUILA.]

ANTI'PATHY (from the Greek ἀντιπάθεια, compounded of ἀντί *contrary*, and πάθος *feeling*), properly signifies an involuntary dislike or aversion entertained by an animate being for some sensible object. Thus a man may have an antipathy to particular smells or tastes—a turkey-cock to the colour red, or a horse to the smell of raw meat, &c. There is no doubt that many antipathies are natural, and do not arise from any accidental circumstance: such as the aversion in mankind to the tastes and smells of many drugs, and of bodies in a state of putrefaction. Such natural antipathies may, however, in many cases, be overcome by habit; as in the case of surgeons, who soon learn to conquer the disgust occasioned by the effluvia arising in the dissection of the human subject. Some nations constantly eat food which the rest of mankind would nauseate, as the Esquimaux, who live on whale blubber and train oil. When the Cossacks were in London and Paris, in 1814, they sometimes drank the whale oil from the lamps in the streets: probably an Englishman or Frenchman would, if starving, reject the draught which the Cossack considered as a luxury. It is moreover quite conceivable that individuals may have such physical peculiarities as will cause them to feel pain from impressions on the senses, which, to the generality of mankind, are indifferent, or even pleasurable: thus some persons are painfully affected by the smells of certain flowers or perfumes, which are commonly considered agreeable, and are sold as means of sensual enjoyment. Many antipathies, however, are not natural, but acquired, and arise from our associating certain objects with the idea of something terrible or dangerous. Thus people acquire antipathies to spiders, earwigs, wasps, snakes, rats, and other animals, from forming exaggerated notions of their powers of harming mankind; and by encouraging such aversions, they may acquire so great sensitiveness and acuteness in distinguishing these animals by the smell, sight, or hearing, that they may be aware of their presence when other people are unconscious of it. Persons may acquire antipathies to certain kinds of food by having been surfeited with them, or by having been accustomed to eat them for long periods of time, as under a medical regimen during an illness; or because they are made of substances which they consider as unclean, or because they are unfashionable, as being eaten by people whom they think less refined and delicate than themselves. This may not unfrequently be observed in persons of narrow and feeble minds, and more especially in children, in whom such fanciful dislikes ought to be carefully but not harshly corrected. See Locke's 'Essay on the Understanding,' b. ii. c. 33, §§ 7 and 8.)

Antipathy properly means, as we defined it, a dislike of an *animate* being for some *sensible* object. Its meaning, however, is sometimes improperly extended to *inanimate* beings; a phraseology now nearly obsolete, but which was much used by the ancient naturalists, who would, for example, have said that an alkali had an antipathy to an acid, or that water had an antipathy to oil. At other times the word is restricted to animate beings, but is applied to things which are not objects of the senses. Thus it has been said that the mind has an antipathy to certain classes of actions; by which it is meant that it is endued with an innate faculty of distinguishing between right and wrong. [MORAL SENSE.]

It is sometimes stated that *antipathy* is the contrary of *sympathy;* but this is not strictly true, at least as respects the use of those two words in modern language. Sympathy means *joint sensibility*, or the feeling of pain or pleasure in consequence of pain or pleasure felt by another sentient being. Thus a person who pitied the misfortunes of another, or who felt delight in the same pursuits, amusements, or studies, as another, would in either case be said to sympathise with him. Sometimes sympathy is applied to the simultaneous irritability of different parts of the body; thus one eye is said to sympathise with the other, when an injury inflicted on one is felt by both.

ANTIPHLOGISTIC TREATMENT (from two Greek words, ἀντὶ, *against*, and φλόγωσις, *inflammation*), is the means of removing or lessening inflammation, and of obviating its effects. As it would be out of place here to consider fully either inflammation, or its causes, we shall merely state that these last are, either mechanical, as wounds, bruises, &c., or of a more general nature, as atmospheric changes operating on the body from without, or altered conditions of some of the organs or functions of the body, operating within, and influencing, more or less, the rest of the system. The effects of the first set of causes are, primarily, always local, but sooner or later become general, that is, affect the whole system; the effects of the second set of causes may be, primarily, either local or general; but when local, having a much greater tendency early to become general. The local effects seem to consist in an alteration of the vital action of the part, accompanied with *pain, swelling*, and increased *heat* and *redness*. The general effects are disturbance of various functions, most usually a diminution of the functions of secretion, exhalation, and nutrition, or assimilation: the heart's-action, the respiration, and functions of the nervous system are also affected, but in different degrees and order in different cases. The change of the vital action of the part appears to produce a quickened movement of the blood in the extreme vessels, or capillaries, as they are termed, which are sometimes slightly contracted, though more commonly dilated, so that the blood presently begins to move more slowly, and at length stagnates in the part, as we may see in the white of the eye when inflamed. The blood, too, in the neighbouring capillaries, seems to incline towards the part, while the large arteries leading to it, and ultimately the heart, assume an increased action, which occasions greater frequency and, generally, force of pulse. The consequences of these alterations of the action of the vessels are, the effusion either of some of the constituents of the blood, as the serum or albumen, in their natural state, or their change into substances not found in the blood, or any other fluid of the body, in its healthy state. These become the source of further change of structure, as suppuration, ulceration, &c., and the cause of disturbance in the functions of the system, varying with the seat of the inflammation, its intensity, and other circumstances.

The means of preventing or moderating these constitute collectively the antiphlogistic treatment and regimen. We shall here briefly notice the chief of these.

Blood-letting.—We have just stated that one of the effects of inflammation is to produce effusion of the serum or lymph of the blood, the extent of which depends on the quantity of blood which goes to the parts affected. The processes of inflammation, in its earlier stages, may be very certainly restrained or arrested by diminishing that quantity. This is done by abstraction of blood, either local or general. If the inflammation be allowed to proceed, suppuration, ulceration, or other changes, and destruction of parts, according to the texture affected, will ensue. Now, abstraction of blood, though it may prevent the extension of suppuration and ulceration to parts not yet affected, is rarely found effectual in checking the formation of pus or *matter*, where that has been already established. We see then the necessity of the early employment of bleeding, and the other antiphlogistic means, if we desire them to be productive of the greatest amount of benefit. The prejudices and prevailing habits of the people are, however generally in direct opposition to such beneficial measures; and too often timid practitioners allow their judgment to be overborne by the importunate requests for delay of the well-intending but ignorant relations. Thus the time when these measures would have proved most serviceable, is allowed to pass over; and when at last put into practice, their good effects not being so conspicuous, they are not so highly appreciated as they would be if employed at an earlier period. Indeed, at a very late stage, far from being useful, they are decidedly hurtful. (See the case of a professional man mentioned under the article ABSTINENCE.)

During inflammation of shut sacs or cavities, that is, those cavities of the body which do not communicate with the external air and which are lined with *serous* membranes, the disposition to effusion of much lymph, or the albumen of the blood, is greater than in other cases. To prevent this, more prompt and vigorous measures must be used. Modern physicians have ascertained that mercury, especially in combination with opium, has a powerful influence, not only in preventing the effusion of lymph, but in removing it soon after it is effused: an example of this is witnessed when, in the inflammation of the eye, called *iritis*, the pupil is filled up, and vision prevented by the lymph effused; yet this is speedily removed if a sufficient quantity of mercury be early introduced into the system. This, then, constitutes another valuable antiphlogistic means.

Purgatives.—The quantity of blood in the system, and the amount of serum, may be greatly lessened by the use of purgative medicines, especially the saline purgatives, which generally produce very liquid motions, consisting of a large proportion of serum. These are not only proper, but constitute an essential part of the antiphlogistic treatment.

Nauseants, that is, such doses of emetic medicines as occasion a constant feeling of sickness, without causing vomiting, reduce the action of the heart, and lessen the tendency to effusion, while they promote the absorption of the fluid already effused. They are, consequently, very valuable auxiliary agents in subduing inflammatory diseases.

Diaphoretics.—The quantity of blood may be diminished, and its acrimony lessened, by increasing the perspiration or discharge from the skin, which in most cases of inflammation is lessened, and in some altogether suppressed. By this diminution or suppression of perspiration, not only more blood is retained in the system, but also those salts and acids which in a healthy state find an outlet by this channel. The means of increasing perspiration are termed diaphoretics, or sudorifics. These, however, seldom produce the desired effect, if there be much heat of surface, that is, of the skin. This must previously be moderated by the use of the means already stated, namely, bleeding and purgatives, and also by the use of

Refrigerants.—These consist of cooling drinks to be taken internally, and cold applications, as cloths dipped in iced water, or vinegar and water, or even ice itself, or evaporating lotions laid upon the part affected. The cold *affusion* is often very serviceable in reducing the temperature and procuring sleep, during which a flow of perspiration, which frequently proves critical, is apt to occur.

It is self-evident that no good can follow the use of any or all of these means of lessening the quantity of blood in the body, if we continue to supply the means of forming it as fast as we remove it. The *diet* of the patient is, thefore, *a*, we might almost say *the*, most important point in the treatment.

During inflammation, as stated above, the functions of secretion and exhalation, as well as of nutrition, are lessened or entirely suspended; there is, therefore, no means of consuming or disposing of the nutritious matter already contained in the blood. How inconsiderate then, and how absurd it is, if life be valued at all, to use means which greatly increase this? Persons do not die of inanition, or from the effects of the absolute privation of food, under many days or weeks (see the two cases narrated under ABSTINENCE), while thousands, millions, die of inflammatory diseases, in a period varying from a few days down to a few hours. At the beginning of all severe inflammations, there is a failure of the appetite; this intimation on the part of nature, ever watchful for the preservation of her works, cannot be slighted with impunity. Reason and experience strictly enjoin an immediate attention to the diet. Its quantity should be lessened, and in most cases its quality changed. In respect to the reduction of quantity no limit need be placed at the commencement, as it can never be reduced too low; but during convalescence careful regulation of it is necessary, that it may not be insufficient on the one hand, or excessive on the other. Still there is much less likelihood of erring on the side of deficiency, than of excess. The vessels of the part being much weakened, are again easily distended, and the inflammatory process renewed; hence the frequency of relapses. Dr. Baillie has recorded it as the result of his experience, "that he never observed a person having a relapse of *fever* where it has not been caused by eating animal food." It may be well to explain here in what way animal food proves hurtful. During its use the blood requires more frequent purifying by exposure to the air in the lungs, or by respiration. To effect this, not only is the more frequent respiration necessary, but also the heart's action is increased, so that the blood is propelled with greater frequency and force, and consequently the distention of the vessels of the inflamed part is increased. The greater frequency of the respiration, occasioned by the greater demand for oxygen, during the use of animal food, is illustrated by the experience of the workmen in diving-bells, who require the air to be renewed much more frequently when living upon animal food and drinking spirituous liquors, than when living on vegetable food and drinking water. For this reason, the pearl-divers of Ceylon, who live exclusively on rice and other vegetables, can remain much longer under water, without requiring to come to the surface to breathe, than any Europeans who live on a mixture of animal and vegetable food. Animal food and spirituous or fermented drinks must be strictly interdicted at the commencement of inflammation, and their use be avoided till the permission of the medical attendant be deliberately and voluntarily given; previous to which mild, farinaceous food, and diluent drinks, should constitute the only diet.

Rest.—A person in a horizontal position respires less frequently than when in an upright position; the heart also pulsates less frequently. In every case of inflammation affecting the system generally, the patient should be confined to bed; and as there is mostly diminished power of the muscular system, all unnecessary exertion should be avoided. Numerous visiters should not have access to the sick-room; for speaking, which requires the exercise of the respiratory organs, fatigues the patient, and quickens the circulation. Besides this, the air is vitiated by the respiration of visiters. A supply of pure and cool air is requisite in all inflammatory complaints, but especially fevers, both for the benefit of the patient and the safety of others.

The repose of the mind is as essential as that of the body. All causes of anxiety should, when possible, be removed, and cheerful looks be put on before the patient, both by the physician and the attendants, in order that, as far as practicable, he may be inspired with confidence and entertain hopes of recovery.

This is a very brief outline of the means termed antiphlogistic, by which we attempt to restore both the part affected and the system generally, to the natural and healthy state, when labouring under an inflammatory attack. The special application will be given as each disease falls under notice, and we need not here do more than endeavour to impress upon every one a conviction of their importance. "Under favourable circumstances inflammation is more completely under the control of remedies than any other disease; and nevertheless, it is more or less concerned in producing a very large share of the mortality in every part of the world." (See Alison's 'Outlines of Pathology.')

ANTIPHONY, in music (ἀντιφωνία, alternate singing), the ancient name for a kind of anthem, the verses of which were chanted by each side of the choir, alternately.

The fathers of the church pretend that the method of antiphonal singing was revealed to St. Ignatius in a vision, who taught it to the Greeks. St. Ambrose introduced it in the Western churches about the year 374. The chanting of the Psalms in our cathedrals is a close imitation of the ancient antiphony.

The 'Antiphonary' or 'Antiphonarium,' was a book in which the antiphonies were written; and, being copied by hand, was generally a costly volume. Some specimens entailed an expense which in present money would be equivalent to nearly 100*l*.

ANTIQUARIES, SOCIETY OF. Mr. Gough, in the introduction to the 'Archæologia,' fixes what he considers to have been the earliest foundation of the Society of Antiquaries to the fourteenth year of the reign of Queen Elizabeth, A.D. 1572; when a few eminent scholars, under the auspices of Archbishop Parker and Sir Robert Cotton, united their efforts for the preservation of the ancient monuments of their country. The members met for near twenty years at the house of Sir Robert Cotton, and as early as 1589 determined to apply to Queen Elizabeth for a charter of incorporation; a manuscript still remaining in the Cottonian collection (Titus, b. v. fol. 184) preserves the reasons which were urged at this time in support of the petition. But whether the petition was ever presented, or what was its success, does not appear. The writer of the life of Carew, the Cornish antiquary, says, their hopes were frustrated by the queen's death. This society, however, admitted members till 1604; about which time King James I., alarmed for the arcana of his government, and as Hearne conceived for the Established Church, thought fit to dissolve it. An attempt to revive the society was made in 1617, in an application for a charter, through the Marquis of Buckingham; but this also appears to have failed.

From this time to the beginning of the 18th century the society ceased to exist; or, as Mr. Gough expresses it, remained in abeyance.

In 1707, a number of gentlemen, attached in a similar manner to the study of our national antiquities, agreed to meet weekly for the same purposes as the former society, on a Friday evening, at the Bear tavern in the Strand. Among these were Humphrey Wanley; Mr. John Talman; John Bagford; Peter Le Neve, Norroy; Mr. Holmes, the keeper of the Tower records; Madox, the Exchequer antiquary; Mr. Batteley; Mr. William Elstob; Stebbing, the editor of Sandford's 'Genealogical History:' and Mr. Sanderson, clerk of the Rolls. Le Neve was at this time president. In 1708 they removed their meetings to the Young Devil tavern in Fleet Street, and soon after to the Fountain tavern over against Chancery Lane. Here they were joined by Samuel and Roger Gale, Dr. William Stukeley, Mr. T. Rymer, Browne Willis, and Anstis. The plan of their pursuits, comprising everything which such a body of men might be expected to do for the illustration of their national antiquities, appears to have been drawn out for them by Humphrey Wanley.

In 1717 the members re-founded, or rather re-constituted, their society, and made their first election of officers; Peter Le Neve, Esq., was president, Dr. William Stukeley, secretary, Mr. Samuel Gale, treasurer, and Mr. John Talman, director. At this time also George Vertue, the engraver, became an active member, and was appointed sub-director. The number of members was limited to a hundred, and no honorary members were allowed. The minutes of the society begin January 1, 1718; whence it appears that every member, or whoever was admitted to be present, brought from time to time whatever they had of their own, or their friends', that was curious or uncommon; as coins, medals, seals, intaglios, cameos, manuscripts, records, rolls, genealogies, pictures, drawings, printed books, extracts, or even memoranda; a few produced dissertations. In 1727 the society removed to apartments in Gray's-Inn, and afterwards to the Temple; and, for a very short period, seemed to decline. In 1728, however, they renewed their meetings at the Mitre Tavern in Fleet Street, fixing them to Thursday evenings, after the Royal Society had broken up. In 1753 they removed from the tavern to a house of their own in Chancery Lane.

In 1750, it was unanimously resolved to petition the king for a charter of incorporation on the plan formed in 1717, with improvements. This, by the concurrence of the Earl of Hardwicke, then lord chancellor, was obtained in the following year, when his majesty having declared himself 'Founder and Patron,' the society became incorporated by the name of 'President, Council, and Fellows of the Society of Antiquaries of London;' they were empowered to have a body of statutes, and a common seal, and to hold in perpetuity lands, &c., to the yearly value of 1000*l*. The council to consist of twenty-one persons, including the president, and to be elected yearly with the other officers. The first council named in the charter, bearing date November 2, 1751, pursuant to the powers therein given them, re-elected as members the other persons not particularly specified. In 1781 the society removed from Chancery Lane to Somerset Place, where his majesty King George III. had been graciously pleased to grant to them, as well as to the Royal Society, appropriate apartments. The Society of Antiquaries held its first meeting there on January 11, that year. It now occupies apartments in Somerset House, and has recently [Nov. 1858] exchanged its old meeting-room in the same building, for that till lately occupied by the Royal Society.

The anniversary of the society is held on the 23rd of April, when ten of the twenty-one persons of whom the council consists are annually changed. The election of members is by ballot; a certificate having been signed by three or more fellows, is previously exhibited for four successive meetings (including those of proposition and election), except in the cases of peers, members of the privy council, and judges, who may be proposed by a single member, and balloted for upon the same evening. The election is determined by a majority of four-fifths. Every member pays an admission fee of five guineas, and two guineas a year; or an additional sum of twenty-five guineas to the admission fee, to be constituted a member for life. The society's meetings are held on Thursday evenings at eight o'clock, in apartments in the front building of Somerset House. The session of the society begins with the third Thursday in November, and ends with the third Thursday in June. The total number of Fellows of the Society of Antiquaries, on April 23rd, 1858, was 635. The presidents, since the incorporation of the society by charter, have been:—1750, Martin Folkes, Esq.; 1754, Hugh Lord Willoughby, of Parham; 1765, Charles Lyttelton, LL.D., Bishop of Carlisle; 1768, Jeremiah Milles, D.D., Dean of Exeter; 1784, Edward King, Esq., (temporarily elected by the council); 1784, George Ferrars Townshend, Baron de Ferrars of Chartley, afterwards Earl of Leicester and Marquis Townshend; 1812, Sir H. Charles Englefield, Bart. (temporarily elected by the council); 1813, George Earl of Aberdeen; 1846, Philip Earl Stanhope (then Lord Mahon).

By an Act of Parliament, 5 Geo. IV., chap. 39, the President of the Society of Antiquaries for the time being is declared to be an official trustee of the British Museum. By another Act, 3 Will. IV. c. 4, the president and council of the society have to elect one of the five additional trustees of the Soane Museum.

ANTIQUES (from the Latin *antiquus*, ancient), a term used in the English language, somewhat vaguely, to designate 'ancient works of art.' The term properly refers to works of Grecian art in sculpture, rilievi, engraving of gems, medals, works of ornamental art, &c. As these arts flourished in the states of Greece, and also under the Roman empire (though probably they were always successfully cultivated chiefly by Greeks), it is scarcely possible to find any precise chronological limits that shall determine whether a work of art belongs to the *antique* or not. No work of a date later than the overthrow of the western empire would, however, be called an antique, and the term is perhaps not applied with any strictness to works produced during the decline of the empire.

ANTIQUITIES. This term is sometimes used as synonymous with antiques, but generally it has a wider signification. Books that treat of Greek and Roman antiquities, to which the term is sometimes confined, treat not only of works of art, but of political constitutions, judicial and legislative forms, religion, architecture, domestic manners, naval and military affairs, weights and measures, mode of reckoning time, &c. Some of these branches of inquiry are capable of illustration, both from ancient writings that remain and from existing works of ancient art; some can only be known to us from the study of ancient writings. This extensive signification of the word *antiquities*, though certainly not very precise, still keeps up a distinction between antiquities, as thus understood, and the *political* history of the Greeks and Romans, and the study of the Greek and Roman *languages*.

The study of *antiquity* is in like manner understood to mean the study of all that belongs to the Greeks and Romans; of all the knowledge concerning them that has been transmitted to our times: the word philology is used in this sense in Germany. Under the general term *antiquity*, then, we may class all the several subjects which it comprehends; such as ancient forms of polity, ancient systems of philosophy, of astronomy, with political history, ancient architecture, sculpture, poetry, &c.

But it is manifestly too confined a use of either term to restrict it to Greece and Rome. With the increase of our knowledge of the durable memorials which man has left behind him in various parts of the earth, we have come very properly to apply the term *antiquities* to the monumental remains and to the works of art of most nations. We now speak of Egyptian, Assyrian, Persian, Hindoo, Peruvian, Mexican, Danish, and British antiquities, when referring to the works of art existing in these countries or collected in museums. The term antiquities, in this extended application, when not specially used with reference to works of art, is also understood to comprehend history, mythology, &c.

ANTI'QUITY. [ANCIENTS; ANTIQUITIES.]

ANTIS. A portico is said to be *in antis* when columns stand in a line, in front, with the antæ or projecting ends of the side walls of the temple or other building. [ANTÆ.] There is a good example of the portico *in antis* in North-Audley-street, London, forming the entrance to an episcopal chapel there. [TEMPLE.]

ANTI'SCII, an old astronomical term derived from the Greek, signifying those whose shadows are in opposite directions. It is applicable, during part of the year, to any two persons, one or both of whom reside within the tropics; and during the whole year, to any two persons, neither of whom lives within the tropics, and both in different hemispheres.

ANTISCORBUTICS (from ἀντί, 'against,' and *scorbutus*, a barbarous word, intended as the Latin for *scurvy*), the remedies, real or reputed, against scurvy. The term scurvy is popularly, but incorrectly, given to two distinct diseases, which arise under different circumstances, spring from different causes, present few symptoms in common, and are cured by means not only unlike, but diametrically opposite. The confusion has crept in owing to the skin in true scurvy occasionally, but by no means invariably, peeling off in scales or scurf; while in the other disease or diseases, improperly termed scurvy, desquamation, or other affection of the skin, is an essential and invariable symptom, the portions or scales of which being commonly called scurf, the adjective scurfy has insensibly come to be used as a substantive, and to be applied indiscriminately to the two diseases. The one occurs mostly at sea, hence called sea-scurvy, and is, owing to temporary causes, capable of affecting persons of any constitution; the other occurs mostly on land, is owing to more permanent causes, and is always connected with a peculiar constitution. The necessity of making this distinction is manifest, since the remedies for the one disease are few and certainly efficacious; the medicines for the other are multifarious and generally very inefficacious. This circumstance points out an essential difference between the two disorders.

For a long period the men employed as seamen, both in the royal and commercial navy, were dreadful sufferers from this disease. In 1593, Admiral Hawkins states it as within his personal knowledge that 10,000 men had perished of scurvy; and at a much later period, Commodore Anson, in his voyage round the world, lost four-fifths of his men from its ravages. On an attack, the patient began to lose his natural and healthy colour: the skin, first of the face, and afterwards of the rest of the body, became pale, and assumed a bloated appearance; the lips, instead of a rich vermilion, acquired a greenish tinge: indeed, the countenance in this disease is always very much depressed, indicating a corresponding state of mind. The patient is conscious of weariness, and is averse to exertion; and when that of a bodily kind is attempted, his unfitness for it is seen by the weakness of the knees (which often become stiff and contracted) and of the whole muscular system, greatly increased frequency of breathing following the least effort. The skin is dry, sometimes rough, but more generally smooth and shining, with spots of a red, blue, or black appearance, according to the length of time that the blood has escaped from the vessels, which is the cause of these stains. The limbs become dropsical; the gums, spongy and swollen; ulcers or any sores, cuts or scratches, bleed profusely and cannot be healed; even old ulcers break out anew, and broken limbs, apparently firmly united, separate again, and cannot be reunited so long as the disorder continues. The blood when drawn scarcely coagulates, but remains loose and flabby; yet during the whole of this state the appetite generally continues good. These symptoms all denote great debility, which is occasioned by a peculiar alteration of the blood, and is produced by the causes we have now to mention.

One of the most extensive and powerful causes of debility is constant exposure to a cold and damp atmosphere. The construction of ships was formerly such that the sailors were continually exposed to the operation of this cause, which was further aided by the unwholesome exhalations from the bilge-water, the sand used for ballast, and the remains of animal and vegetable matter which were strewed about the ship: no means of removing or lessening these causes existed, from the utter absence or imperfect nature of the means of ventilating the ship, or washing it without increasing the dampness. The sailors were also very inattentive to personal cleanliness, were unprovided with soap, and were too insensible of the advantage of changing their dress when wet, and were also without the opportunity of changing or washing and airing their bedding. The measures adopted by Captain Cook, on the occasion of his second voyage round the world, were very similar to those since universally pursued. Out of 318 men, during a voyage of three years and eighteen days, throughout all climates, from fifty-two degrees north to seventy-one degrees south, he lost only one. For this, in the year 1776, he received from the Royal Society the Copley medal. (See Kippis's 'Life of Cook,' 1788, p. 315.)

By the change effected by Sir Robert Seppings in the construction of ships, and the substitution of iron instead of sand for ballast, and of iron tanks instead of casks for water; by the efficient means he has devised for ventilating the ship, without exposing the persons of the sailors to cold; and by the employment of portable iron fire-places in different parts of the ship, as well as by a change of bedding, and a proper allowance of soap to each sailor—these debilitating causes no longer exist, or are rendered powerless.

Another cause of debility was either excessive fatigue or deficiency of proper and regular exercise; the former cannot always be avoided, as in the case of much bad weather, when the labour of all hands is increased, or great sickness among the crew, which requires more exertion on the part of the healthy. But deficient exercise can always be avoided by the officers finding employment, or inventing amusing occupation for the sailors, and above all for the marines, who, having less active duty in the ship, were the most frequently attacked by scurvy. Intemperance also greatly contributed to prepare the system for a scorbutic attack, but this vice is now much repressed.

None of these causes singly, nor indeed all of them combined, are adequate to produce scurvy, unassisted by some specific cause, which cause is to be found in the diet. The diet of seamen during long voyages was formerly merely salted meat and biscuit; fresh animal food or recent vegetables formed no part of it. It was also often deficient in quantity.

Salt, if taken in moderation, facilitates digestion, but if in excess, hinders the digestion of the food, even of fresh meat and vegetables; when employed as a means of preserving meat, it hardens it, and impairs its nutritive power, as well as renders it more difficult to digest. Such meat is less nourishing, but more stimulating, than fresh meat, and its long-continued use produces what may be termed the disjunctive inflammation, owing to which old wounds and ulcers break open, and fractured bones separate after re-union. The salt seems to be pernicious in a two-fold way: first, by lessening the nutritious power of the meat; and secondly, by its stimulating properties. The former of these, unaided by the latter, is sufficient to produce scurvy, if the predisposing causes of cold, moisture, and imperfect or excessive exercise be in operation. The diminution of the quantity of food, and not its quality, was the principal exciting cause of scurvy in the Millbank Penitentiary in 1819. [ABSTINENCE.]

In what way the absence or inadequate supply of fresh vegetables operates has not been ascertained. That the deficiency of this article of nutriment has a large share in producing scurvy is established by the facts, that before the extensive introduction of esculent vegetables into Britain, scurvy was almost as common on land as at sea; and also by the rapid disappearance of scurvy from among the crews of ships, so soon as they procure a supply of vegetable articles of diet of any kind, but more particularly those belonging to certain tribes of vegetables,—as the Hesperideæ or Aurantiaceæ (the orange tribe), the Grossulariaceæ, or gooseberry tribe, which are all acid vegetables; and the Cruciferæ, or mustard tribe, containing cabbages (from which sour-kraut is prepared) and the well-known scurvy-grass, which are alkalescent vegetables; the Coniferæ, some of which yield spruce, &c.

These vegetables, or the articles prepared from them, constitute the *antiscorbutics*, or means of preventing and curing sea-scurvy; but they are not all of equal value, some far surpassing the others in efficacy. Those are the least valuable in which no vegetable acid greatly predominates, so as to impart to them an acid or acidulous taste. Hence the Cruciferæ are not so useful in their natural state, as the name of scurvy-grass, bestowed on one of them, would seem to indicate; but when by their fermentation, as that of cabbages to form sour-kraut, a vegetable acid (acetic acid? or vinegar) is produced, they rise in the scale of antiscorbutic power. But at the head of all, the hesperideæ deserve to be placed, the members of which contain citric acid: accordingly, any of the species may be employed; but the most powerful belong to the genus *Citrus*, especially the *Citrus limonum* (Risso), the well-known lemon, since the introduction of which into the navy, in 1796, scurvy has almost ceased. It may be used in various ways; the best is in the form of the fresh fruit sucked by the patient: but in the absence of this, lemon-juice may be employed, and this is the usual mode in the naval practice. Several gallons of it, having a tenth part of spirit of wine added to preserve it, are supplied to each ship, and in about a fortnight after leaving port its use is begun; each sailor is allowed one ounce of it and one ounce and a half of sugar to mix with the grog, or in many instances with wine, a stated quantity of which is granted in lieu of a certain quantity of spirits, which is withdrawn. This has the effect of almost invariably preventing scurvy affecting any of the crew; but should symptoms of the disease begin to show themselves, they quickly disappear by an increase of the quantity of lemon-juice. Citric-acid, which has been crystallised and again dissolved in water, is not so efficacious, neither is vinegar, nor any other vegetable acid, such as tartaric, or malic, so useful, though the fruits containing them (unripe gooseberries, tamarinds) are the best substitutes for lemons, when these cannot be procured.

No one, as far as we know, has attempted to explain how these vegetable acids produce their beneficial effects. It may be remarked, however, that all acid fruits have a very cooling and soothing effect in many complaints; they are among the most useful refrigerants, and often sit on the stomach and restore its power, when in a very irritable or weakened state. This is particularly the case where the powers of the stomach and nervous system have been much impaired by intemperance, especially from the abuse of spirituous liquors, in which tartaric acid is eminently serviceable; even during a fit of intoxication, a draught of vinegar will restore the drunken man to his senses more speedily than any other means. These acids appear to exert a very considerable vital action on the system generally, but especially on the nervous centres. Further, lemon-juice and vinegar exercise a chemical influence on many articles of food difficult of digestion, as veal; hence the practice of serving these articles to table accompanied by one or other of these acids. If the salt has rendered the meat hard and difficult of digestion, may not these acids produce some change in it, rendering it less so by their chemical properties, as well as by their general action heightening or increasing the vitality of the stomach, and consequently its power of extracting the nourishment? Some local effect is produced by the direct application of lemon-juice, as slices of lemon placed on the ulcers hasten the healing processes.

Mineral acids, such as elixir of vitriol, are found less useful, though they and other strengthening medicines, such as sulphate of quinine, may occasionally prove serviceable, when lemon-juice is wanting, or fails in effecting a cure, which has happened in some very rare instances. Chloride of soda appears to have some claim to a favourable regard; but at present we have too little experience of it, in this respect, to speak positively of its antiscorbutic power.

In addition to the lemon-juice, ships intended to be sent on long voyages are supplied with animal food, so prepared, as to be almost as fresh at the end of six years as if it had been killed but a few days, and dressed the day previous to its being used. This valuable discovery, which tends so greatly to lessen the inconvenience of a sea-life, as well as to secure the health of those devoted to it, was made by Mr. Appert: the mode of effecting it, and the principle on which it depends, will be explained under ANTISEPTICS.

After every fair degree of merit is assigned to other means and articles, the main instrument of banishing scurvy from among the number of diseases incident to a sea-life has been the liberal use of lemon-juice. The nation owes a deep debt of gratitude to those who effected its universal introduction into the naval service, and who lived to witness the beneficial effects of their enlightened views: these were Earl Spencer, who was first lord of the Admiralty in 1795, and Sir Gilbert Blane, physician to the fleet, and at the head of the Navy Medical Board in 1795. But for their exertions, it seems scarcely probable that our navy could, during the twenty years of the war which followed that day, have achieved those victories which have rendered our country so illustrious. (See paper on the comparative health of the British navy, by Sir Gilbert Blane, in his 'Select Dissertations on Medical Science,' London, 1822; also in vol. vi. of 'Transactions of the Medico-Chirurgical Society.')

The historian of Anson's voyage, speaking of scurvy, says, "The cure seems impossible by any remedy or by any management that can be employed." In the present day, instead of the remedy being unknown, it is, happily, the disease; a fact which suggests the most important subject for contemplation, and justifies the reflections and language of Sir Gilbert Blane: "Does it not afford a cheering and consolatory prospect, 'amidst the thousand shocks that flesh is heir to,' that there may be still in store for us, in the boundless progression and endless combinations of knowledge, other hidden means of advancing human happiness, of mitigating human misery, and of making accessions to the dominion of man over nature, which have not yet been dreamt of in our philosophy." [SCURVY.]

The other diseases to which the name of scurvy has been improperly given, and some of the remedies for which are termed antiscorbutics, have no connection with sea-scurvy, or its remedies. These various affections of the skin are more or less connected with a scrofulous constitution, to which are owing the disordered functions of the digestion, whence these eruptions spring. Acidity in the stomach is a concomitant and characteristic symptom of these diseases, for the cure of which vegetable acids are unavailing, though the mineral acids, by their strengthening virtues, are often serviceable. These so-called scorbutic affections are of very frequent occurrence among persons subject to gravel and gout, which are, at the commencement, caused by acidity in the stomach: the appropriate means of cure for both complaints are alkalies [ANTACIDS], the very opposite of the means useful in true scurvy.

The nostrums vended under the name of antiscorbutics, and intended for these cutaneous diseases, though varying in their composition, mostly contain, as their active principle, some preparation of mercury, often a very poisonous one, which is always hurtful in sea-scurvy, and can only be serviceable in particular cases of the other kinds. Its use requires the greatest caution, directed by the utmost skill; the employment of such articles should, therefore, be carefully avoided.

ANTISEPTICS, from ἀντὶ, *against*, and σήπομαι, to *putrefy*, the means of preventing those changes in organised matter which are comprehended under the term putrefaction. All organised bodies consist of different materials, which are designated their proximate principles, and these again are formed by the union or combination of certain ultimate principles. An organised body, therefore, is always a compound one, and the tendency of its original or natural proximate principles to form others, and, at last, to be resolved into the ultimate elements of which they are formed, is the occasion of putrefaction, which takes place in all bodies, sooner or later, according to the circumstances in which they are placed. To give an example of each: flour, prepared from what was once a living and organised body, called a seed, contains two proximate principles, gluten (bird-lime) and starch: each of these is resolvable into definite combinations of what are termed simple or elementary bodies, of the same nature as the constituents of inert or inorganic matter; the most common of these are oxygen, hydrogen, carbon, and nitrogen. The first or proximate principles are only met with in organised bodies; the latter equally in organised and inorganic matter. Oxygen, for instance, forms a portion of the air which we breathe, and also of water; hydrogen forms a portion, or is an element, of water; nitrogen is found in the atmospheric air; and carbon exists in the diamond, in the charcoal obtained from wood, or from animal matter.

All organised bodies spring from parents similar to themselves, possessed of, or endowed with, a vital principle. Every such body possesses the power of assimilating to itself matter introduced from without, whether inorganic, as table-salt, or organised matter, as dead animal and vegetable substances, in the case of man and some other animals, or merely inorganic matter, as in the case of vegetables. After being received into the interior of the body, these matters undergo changes previous to being distributed to that part of the frame destined for the reception of the different proximate principles which are formed out of them by the vital processes of digestion and assimilation. When deposited in the part intended for them, they would speedily enter into fresh combinations, were not their tendency to do so controlled by the agency of the living principle, which counteracts the usual chemical affinities of the constituent or elementary principles. When this principle is weak, or does not act with sufficient energy, either through the whole frame or in any particular part of it, the elementary principles manifest a disposition to exert their ordinary affinities which would lead to the decomposition of a part or the whole. Partial decomposition occurs when a limb or other part of the body has been the seat of such violent inflammatory action that its structure is changed, and its vitality destroyed, so that it sloughs, as it is technically called, that is, becomes dead: complete decomposition occurs when the vital principle quits the entire frame, that is, when death of the whole body takes place, and putrefaction begins. But the presence of the vital principle does not always hinder the commencement of putrefaction, as we see the tendency to it manifested in the worst kinds of fevers several days before dissolution: on this account they were termed putrid fevers, and were conceived to be owing to putrescency of the fluids, a doctrine common during the prevalence of the humoral pathology. But more correct views of fever have taught us that the changes in the fluids, both as respects their properties and chemical constitution, are consequent upon a change in the vital action of the system, resulting from the impression of a powerfully morbific agent on the nervous or circulatory systems. This impairs the vital force or energy of the frame, and lessens the power by which the chemical affinities were controlled; and hence the early tendency to putrefaction in persons affected with fevers of a typhoid type or character.

The complete departure of the vital principle is not sufficient to occasion the commencement or ensure the continuance of the processes of putrefaction: the concurrence of several other circumstances is necessary. These are air, heat, and moisture: if any one of these be wanting, decomposition will in general be prevented. If the air has an admixture of certain particles or principles, the tendency to putrefaction will be greatly increased; and, on the other hand, impregnating the air with certain other principles, greatly lessens the disposition to decomposition. These circumstances have so large a share in the production or prevention of disease and death, that a thorough understanding of them is of vast importance to the welfare of the community.

The atmospheric air, considered in reference to its chemical composition, is a mixture of nitrogen and oxygen gases, in fixed and uniform proportion, with carbonic acid gas in a small and variable proportion. But close to the surface of the earth, it receives an admixture of particles or principles of different kinds, by which it is contaminated, and rendered less fit for the support of animal and vegetable life. By the respiration of animals, particularly of warm-blooded animals, as man, a portion of the oxygen is withdrawn, and a corresponding portion of carbonic acid gas is substituted in its place. By the respiration of plants, the carbonic acid gas is withdrawn, and an equivalent portion of oxygen substituted. By the mutual action of the members of the animal and vegetable kingdoms, the balance of the constituent elements of the atmosphere is maintained. But by a preponderance of the members of either of these kingdoms, an excess of the one principle and a deficiency of the other will be occasioned. Hence, where there is a large assemblage of men, the air is less fit for respiration, as happens in close apartments: the most melancholy example of this is to be found in the narrative of the Black Hole at Calcutta; of one hundred and forty-six persons confined in this dreadful place, one hundred and twenty-three perished during one night. Trees crowded together in plantations suffer more from deficiency of carbonic acid and oxygen, both of which are required for respiration, than from deficient nutriment by the roots—a fact of which proprietors and managers of timber-plantations are either not aware, or at least they neglect the practice to which it should lead. It may be remarked by every one that on the coast, where animal life acquires an accession of strength from the purity of the air, which abounds in oxygen, vegetable life languishes from the deficiency of carbonic acid. In addition to these sources of deterioration, the air is contaminated by various other means, some occasional and limited in their operation, others more constant and extended in their influence. A brief review of these will here be proper; but, before proceeding to enumerate them, it will afford conclusive evidence of their importance to adduce one example of the influence of even a slight admixture of a deleterious principle with the ordinary constituents of the air. "This gas (hydrochloric acid, or muriatic acid gas) must therefore be very injurious to vegetable life, since so small a quantity as a fifth of an inch, though diluted with 10,000 parts of air, destroyed the whole vegetation of a plant of considerable size in less than two days. Nay, we afterwards found that a tenth part of a cubic inch in 20,000 volumes of air had nearly the same effects." Drs. Turner and Christison, in 'Brewster's Journal,' vol. viii. p. 145.

These are principles with the chemical qualities of which we are well acquainted, and the sources of which we can easily ascertain, and often remove; but there exist others, of the nature and origin of which far less is known, though their effects are very conspicuous: such are the exhalations from decaying vegetable matter, termed marsh miasmata, or malaria, and the exhalations from the bodies of men and animals, when crowded together, or from that of men labouring under certain diseases, as fevers, called the matter of contagion, or from dead animal matter, in a state of putrefaction, termed putrid effluvia. These are the fertile sources of fevers, whatever their form, type, or appellation; and though it is commonly thought that the fevers from vegetable matter are always of an intermittent or remittent character, yet they often assume the continued form [AGUE]; while the effluvia from animal matter mostly give rise to fevers of a continued and typhoid character. (Boot's 'Life of Armstrong.')

What the precise nature of this deleterious principle is cannot be stated, but whatever it be, when received in sufficient quantity into the human system, it seems to act as a ferment or yeast, and produces a series of changes, the ultimate object of which is to reduce the body attacked to a state of putrefaction. We have no test of its presence beyond its effects, but we know the sources whence it springs, and the circumstances which favour its concentration, and occasion the human frame to become more susceptible of its influence. It is only by removing or lessening these that we can escape this insidious foe, and the success which has attended the enlightened measures proposed by physicians and chemists should lead to their extended application. ('Reports of Registrar-General.')

Long-continued calms, in which there is a stagnation of the air, and during which fresh and purer particles of the atmospheric principles do not descend from the higher regions to replace the heated and contaminated air near the surface of the earth, conduce much to the concentration and virulence of these agents. For several weeks before the plague broke out in London, in 1665, there was an uninterrupted calm, so that there was not even sufficient motion in the air to turn a vane. And at the season in which the last plague visited Vienna there had been no wind for three months. To produce agitation in the air, fires were formerly lighted, and pieces of artillery discharged, means altogether inefficient to cause a considerable commotion in the atmosphere at large, though a fire is extremely serviceable in renewing the air of apartments in houses: the only means adequate to this end are beyond our control, though they frequently take place at the moments of the utmost need; these are storms and hurricanes, which, however desolating in their immediate effects, are instruments of great, though less obvious, good. After the hurricane which proved so destructive to the inhabitants of the West Indies in 1780, less disease occurred than had been known before; even those who laboured under sickness at the time were benefited by it; fever, diarrhœas, and dysenteries, but above all, disorders affecting the lungs, were cured. After the excitation of a storm, plants give out more oxygen, which accounts for the delightful and life-giving freshness of the air, of which every one is sensible, who walks out into the fields immediately afterwards.

We may imitate nature, and employ ventilation on a small scale, but with the best effects, in our dwelling-places, hospitals, and sick-rooms. The evils of neglecting this salutary measure contrast strikingly with the beneficial consequences of attending to it. It is remarked by Dr. Macculloch, in his 'Account of the Hebrides,' that while the inhabitants had no shelter but huts of the most simple construction, which afforded free passage for currents of air, they were not subject to fevers; but when, through the good intentions of the proprietors, such habitations were provided as seemed more comfortable and commodious, but which afforded recesses for stagnating air and impurities, which they had not the means, or had not a sufficient love of cleanliness, to remove, febrile infection was generated. The mortal fevers which have occurred from crowding human beings together in small ill-ventilated apartments are numerous. They were termed jail and hospital fevers, from their infesting those places; the survivors of the night in the Black Hole of Calcutta were, almost without a single exception, attacked by fever; and the unhappy victims of the mercenary actors in the slave-trade were often released from suffering by the fevers which resulted from crowding so many into a confined space. To avert such calamitous diseases, we must have recourse to measures which will lessen or remove their causes; such as dispersion of the inhabitants or patients over a larger space; enforcing cleanliness of the apartments and of their persons, and freely ventilating every room. Formerly, in the hospital at Leeds, no patient suffering from compound fracture or other severe accident survived, till the ventilation of the wards was improved. One of the most convincing proofs of the different influence of foul and pure air is to be found in the 'Report of the Lying-in Hospital of Dublin.' In the space of four years, ending in 1784, in a badly ventilated house, there died 2944 children out of 7650. But after freer ventilation, the deaths in the same period of time, and in a like number of children, amounted only to 279. The soldiers of our army have been proved to have suffered severely from a like cause through the want of sufficient ventilation in their barracks. Wherever proper ventilation has been secured, the building, whether hospital, barrack, or dwelling-house, invariably becomes more healthy.

Stagnant water, and the mud which remains after it has evaporated, marshes and places occasionally overflowed, emit exhalations not less noxious than those from decaying animal matter, or the bodies of human beings. These are the more powerful in proportion to the heat; hence in tropical and warm countries, they give rise to the yellow-fever and the jungle-fever, which are rapid in their course, and generally fatal in their close: in colder countries they produce continued remittent and intermittent fevers. The exhalations are always less hurtful in proportion to the activity of the vegetation. The inhabitants of that part of the town of Batavia which is nearest the mud and slime left by the tide, suffer more from fevers than those who dwell next the marshes, unhealthy as these are. In the marshes of Anké, a great number of different kinds of grasses, rushes, &c., grow, and the spaces between these plants are covered with large quantities of the *Pistia stratiotes*, the leaves of which float on the surface of the water, and absorb a great quantity of the noxious vapours as fast as they are exhaled, and change them, by the aid of the sun's rays, into respirable air. This change is effected by the pistia more than by any other plant; for it is known from experiments to be so powerful a preventive of decomposition of stagnant water, that if fishes be put into a small quantity of water, in which they would otherwise perish in the course of a few days, they may be preserved alive for a long time by covering its surface with these singular plants. The utility of a piece of moss introduced into the vase where gold fishes are kept is well known: on this principle depends the health of fishes and other animals in the vivaria, now so common; and the *lemna* or duckweed, and other plants which cover the surface of ponds in summer, render a similar service to the air here, which the pistia does to that around Batavia. Where marshes cannot be drained, the planting them with marsh and aquatic plants, and such trees as alders and poplars, is the best mode of mitigating the evils which result from them. The beneficial effects of draining and forming under-ground sewers are shown in the perfect immunity which London enjoys from ague as an epidemic, contrasted with former times. Dr. Caius, the most eminent physician in England at that period, states, that the mortality of London from ague in 1558 was such, that the living could hardly bury the dead.

When these natural means of preventing animal and vegetable exhalations cannot be employed, we must have recourse to artificial means of disarming them of their potency. Of the measures formerly resorted to for this purpose, some were useless, while others were hurtful to the sick, and could not be practised without the removal of the patients, which can rarely be accomplished. All of them, in point of efficacy and facility of application, fall short of two agents, which bid fair to render every other superfluous: these are the chlorides of soda and of lime. In these preparations chlorine is combined with the bases in such a way as to be susceptible of decomposition, and is evolved with more or less rapidity according to the ingredients or impurities it meets with in the air. The most common of these impurities is carbonic acid gas, which is produced both by the respiration of living animals, and by the decomposition of their bodies when dead. Another product of putrid animal matter is ammoniacal gas, which generally unites with the carbonic acid, and forms carbonate of ammonia, the presence of which may be recognised by the pungency of the air impregnated with it, which affects both the eyes and the organ of smell. Now, it is interesting to remark, that carbonic acid gas has the greatest tendency to unite with the soda or the lime, and to liberate the chlorine. Again, chlorine decomposes ammoniacal gas by abstracting the hydrogen from the nitrogen, and forming hydrochloric or muriatic acid. One example of its beneficial action will prove its utility. Air was passed through blood, which had been left to putrefy for eight days; being then passed through a solution of the chloride of lime, carbonate of lime was deposited, and the air was rendered inodorous and completely purified. These agents can only be productive of benefit within a limited range of atmosphere, yet they may be employed successfully to purify the air of hospitals, sick-rooms, &c.

Quick-lime, or charcoal recently prepared, has been employed to absorb fetid and noxious exhalations, and though inferior to the chlorides, may be used in some cases, such as when the patient cannot bear the smell either of the chloride of soda or of lime. Nitrate of lead is extremely serviceable when put into night-tables or water-closets. When the matter of contagion is supposed to be attached to woollen or cotton clothes, we may expose these to a high temperature, 212° of Fahrenheit, for some hours, by which it will be dissipated.

An equally important means of warding off the effects of exposure to a contagious atmosphere, is to put the body in a posture of defence by strengthening it, and regulating the general health. Increasing the vital force of the system renders it less susceptible of being acted upon by impure air; hence nourishing food and tonic medicines may be regarded as indirectly antiseptics. It is a wise precaution not to visit the sick without previously taking food. But useful as a supply of proper nourishment is, still it is of inferior efficacy, as a protective means, compared with ventilation and cleanliness, as is demonstrated by the instructive fact, that in Great Britain, we were 200 years later in getting rid of pestilence than of famine. Most of the medicines which were formerly termed antiseptics are either tonics or refrigerants: of which cinchona bark may serve as an example of the first class, and the mineral and vegetable acids, as dilute sulphuric acid, and tartaric acid or citric acid of the second. Tonic antiseptics cannot be employed with propriety or safety at the beginning of fevers or inflammatory complaints, but in many diseases a period arrives when they may be usefully administered. The period when their employment becomes safe requires the nicest discrimination on the part of the medical attendant; and too numerous are the instances where their premature employment has rekindled the disease which might otherwise speedily have subsided. We are, however, justified in having recourse to them at an earlier period in those diseases which we know to have a great tendency to lead rapidly to the death of some part; such as in the malignant or putrid sore-throat of scarlet fever; or in continued fever of a very typhoid character.

The refrigerating antiseptics may be beneficially used from a very early period of inflammatory diseases, especially of the young and robust: in such diseases as scurvy (*i. e.* sea-scurvy), they surpass all other remedies.

As the operations of nature in regard to organised matter seem to consist in reducing to their elementary state each individual, or part, when it ceases to live, and in reconstructing others, it forms an interesting and important subject of investigation to inquire in what way the former of these may be prevented, when it is desirable to preserve the whole or a part of organised matter from putrefaction; by what means can the tendency to putrefaction be so modified, that the result of it, though leading to the formation of a substance having a very different character, shall yet be of a kind which may be preserved for a longer period, than the original substance; and how the process of putrefaction may be rendered a useful, instead of a noxious, operation.

There are many substances which, when added to animal matter, prevent for a longer or shorter time their decomposition, such as saltpetre (nitrate of potass), and common salt (chloride of sodium), which last is supposed to act by abstracting the elements of water: certain it is that meat is rendered by salting much drier, harder, less easily digested, and consequently less nourishing. [ANTISCORBUTICS.] Many aromatic substances have a similar power of preventing putrefaction for a time. They were extensively employed in embalming in ancient as well as modern times, as the Egyptian mummies prove. Oils and resinous substances long resist putrefaction, and preserve other substances from it; bitumen, naphtha, and empyreumatic oils are examples of this. Russia leather, which is dressed with the empyreumatic oil of the birch, not only does not become mouldy, but also preserves the books which are bound with it. The process of decomposition is greatly hastened by the agency of fungi, such as those which cause mouldiness, and the more formidable destroyers which occasion the dry-rot. The fungi which cause mouldiness are generally prevented from developing themselves by the presence of some aromatic oil; and the others which occasion the dry-rot in timber may be prevented from developing themselves by the process invented by Mr. Kyan. This consists in combining the albumen of the wood with bichloride of mercury (corrosive sublimate), which it converts into the protochloride, in the same way that animal albumen combines with, and converts into the protochloride, the same compound [ALBUMEN]; the wood is thus rendered insusceptible of the attacks of the fungi. Fungi often attack and destroy the cereal grains, particularly wheat: the worst of these—namely, the *Uredo fœtida* (pepper-brand)—may be prevented from farther developing itself by steeping the seeds for twelve hours in lime-water.

The collections of entomologists and botanists suffer much from the depredations of insects. Those which infest collections of insects may be driven away by placing camphor in the cases, or by introducing a solution of bichloride of mercury into the blood-vessels of larger animals previous to stuffing them. Dried plants, for botanical specimens, may be preserved from the attacks of the *ptinus fur* by applying to them, when perfectly dry, a solution of bichloride of mercury, of the strength of two drachms to a pint of rectified spirit of wine, to which a little camphor has been added. It must be applied to the whole specimen by means of a camel-hair pencil.

ANTISEPTICS are the means of preventing those changes in organised matter which are comprehended under the term putrefaction, and are used in the preparation of PRESERVED FOOD.

All organised substances do not putrefy with equal rapidity, nor under all circumstances. Decomposition goes on fastest in substances which contain nitrogen, and most slowly in those which are richer in carbon: hence, animal matters putrefy quickly; vegetable, especially of a woody texture, gradually. The conditions necessary for putrefaction to take place are, the presence of air, of a certain temperature, and moisture. If any one of these be excluded, the process is prevented. The moisture may either be external, or it may consist of the fluids of the body itself. The bulk of the animal frame is made up of fluids, which must either be dissipated by heat, abstracted by some chemical process, or rendered solid by a very low temperature, if we wish to preserve any animal substance in the state most near that of its natural constitution.

The modes of preserving food are either natural or artificial. The natural modes comprehend those which effect this end by abstracting or excluding one or more of the chief agents—heat, moisture, and air; the artificial, comprehend those methods of preparation or mixture which produce some chemical change in the substance.

1. Abstraction of heat. The presence of heat is essential to the exertion of those chemical affinities which take place during decomposition, or constitute the process; abstracting it therefore checks or suspends them. Most articles of food keep better in cold than in warm weather. When the heat has been so completely abstracted that the juices are frozen (that is, become solid), the preservation of the substance is more effectually accomplished. Indeed they may thus be preserved for many years, perhaps ages. On this principle the Russians preserve their poultry, which they kill in October, and pack in tubs with interlayers of snow. The markets of St. Petersburg are supplied with veal brought from a great distance in this state, as well as with whole hogs, sheep, and fish. The Canadians preserve their provisions in the same way.

A precaution is necessary in thawing the preserved provision: for this end, they should always be put into cold water first. This meets with an example in the case of persons buried in the snow, when recovery is much more likely to be brought about by plunging the individual into cold water, than by placing him in a warm bed.

This method of preserving food is not applicable to vegetables, but when these are frozen they should also be first put into cold water.

2. The abstraction of moisture by heat is employed in drying fish and other animal substances, as beef, bacon, &c.; though in these the rapid tendency to putrefaction makes the employment of a certain quantity of salt, &c., necessary, along with the drying, unless the process be carried on with great rapidity, which may be effected by a high temperature and a free circulation of air. Hence, in many places, where turf or wood is burnt, hams are hung within the wide kitchen chimney. Drying is also employed for the preservation of vegetable substances, such as grain, hay, &c. It is by this means that botanists preserve plants to form a hortus siccus, or herbarium, and herbalists many plants for medical use; but for this purpose a high temperature should never be applied, as it dissipates their active principles.

3. The exclusion of sources of oxygen gas constitutes another means of preventing or checking putrefaction; and as the atmospheric air is the most common source of oxygen, we shall limit our remarks to the means of excluding it. The effect of such exclusion is very great. Reaumur varnished some eggs, and found that at the end of two years they were yet capable of producing chickens; and Bomare mentions an instance where three eggs were inclosed within the walls of a church in Lombardy, and when found at the end of 300 years they had not lost their flavour. Lime-water is the best medium in which to place eggs for long keeping. But more valuable articles than eggs are preserved by this means, and in a condition nearly equal to their fresh state. We allude to the method of preserving animal food and vege-

tables, promulgated by M. Appert. This consists in boiling the articles (if meat, the bones must be first taken out) to nearly as great a degree as if intended for immediate consumption; they are then put into jars or tin canisters, which must be completely filled with a broth or jelly prepared from portions of the same meat. The canisters are then corked and covered with a luting, and carefully soldered down. After this, they are placed in a boiler of cold water, to which heat is applied till the water boils, and the boiling of which is continued for an hour; the fire must then be instantly extinguished, and the water soon drawn off, but the boiler must not be uncovered, or the bottles taken out, for one or two hours after. By this method, meat has been kept sound and well-flavoured for many years, and has been sent to all parts of the globe. The process of exhausting the air from the vessel which contains the substance to be preserved, and then effectually excluding the atmosphere, is a method now frequently used.

A simpler method of preserving animal food for sea-stores is the following:—the meat is cut into slices of four to eight ounces, steeped for five minutes in a vessel of boiling water, and dried on a network at a temperature of about 120° Fahrenheit. The liquid or soup formed by steeping the meat is next evaporated to the state of a thick varnish, to which a little spice is added. The dry pieces of meat are dipped into this gravy and dried again; and this dipping and drying are repeated two or three times. The meat will in this dry state remain good for a year or two, and may then be cooked in the usual way by boiling, &c.

The natural methods of preserving organised substances are few and simple; the artificial more numerous, as well as more complex. They consist either in causing such changes in the elementary constitution of a body as shall form a new and less destructible article, or in introducing some additional principle which shall hinder the exercise of the natural tendency of the substance to decomposition.

The first set of means constitute the various kinds of fermentation; with respect to which we may remark, that the products of them are not only little disposed to undergo decomposition, but have also a powerful effect in preventing other substances from undergoing it. The most remarkable of these are acetic acid, or vinegar, and alcohol. The formation of sugar, another product of fermentation, is a powerful means of preserving fruits, in which it is formed spontaneously, or to which it is afterwards added. The addition of sugar is practised in forming syrups, jellies, and preserves.

Those parts of plants which contain much carbon last the longest. In trees cut down and exposed to air and moisture, the bark, which contains most carbon, endures after the rest has perished. The seed also contains much carbon, and when seeds are sent from India to England they are generally wrapped in recently prepared charcoal. When stakes or piles of wood are to be driven into the beds of rivers or marshes, they are previously charred; and to preserve water sent to sea, the inner side of the cask is also charred.

Reverting to the subject of preserved meats, we may state that the use of such condiments is extending in the English navy; and although circumstances which occurred a few years ago excited a painful doubt on this subject, nothing has transpired to disprove the excellence of the diet and the advantage of its adoption, provided common honesty be shown in the manufacture, and common prudence on the part of the purchasers.

Mr. Goldner, a foreigner resident in England, obtained a patent in 1840, for a method of preserving meat, founded chiefly on the plan of Appert. In 1844 the Government first entered into a contract with him: and the first supply was obtained from that source in 1845. The meat was in the first instance used experimentally, and in small quantities; in 1846 larger quantities began to be sent out in some of the government ships; and at length in 1847, it became a custom to send out some of these canisters of preserved meat in most of the ships intended for foreign service. Sir John Franklin's arctic expedition was furnished with a supply of this kind, at a time when the system was yet in an experimental state. That meat, properly secured in the canisters, will remain good for many years we knew, from the fact that part of the stores left on shore by Sir Edward Parry, when he abandoned his ship, were found in excellent condition 20 years afterwards. Another contract was signed in 1847; but in 1848 complaints were occasionally made that the meat thus supplied was defective in quality. Steps were taken by the government to ensure, as was supposed, the due fulfilment of the contract; and a new purchase, to a considerable extent, was made in 1850. A few days before the close of the year 1851, circumstances occurred to show the necessity for examining the stores of preserved meat at Portsmouth. The meat had been prepared at Galatz in Moldavia, and packed in canisters containing about 10 lbs. each; and, from the nature of the process, these canisters must not be opened until the meat is required for food, as the admission of air nullifies the antiseptic processes. It was not known, therefore, until the canisters were opened, whether the bulk of the supply corresponded with the samples. When at the close of 1851 and the commencement of 1852, it was deemed necessary to open all the canisters then in store, it was found that out of many thousand canisters, only a few hundreds contained food fit to be eaten. We need not further allude to this part of the subject, since it relates to a dishonest evasion of a proper system, and not the real value of the system itself.

It has been suggested, that the condition of the meat within a canister may be judged from the appearance of the canister itself. Even supposing the contents of the canister to be good and proper in the first instance, yet if any air gain admittance, a certain extent of decomposition ensues: gas is generated, and this gas causes a bulging or convexity of the canister. If a minute hole be made, by accident or design, or rust, in a canister, the entrance of air will be sufficient to spoil the contents; and hence it is deemed a wise precaution to paint the canisters externally.

The manufacture of preserved provisions is now carried on to a very considerable extent. Mr. Gamble has still (or had recently) in his possession some of the canisters of boiled mutton which he prepared for Parry's expedition in 1824, which Sir John Ross found in good condition on Fury Beach in 1833, and which Sir James Ross found to be equally good in 1849. Canisters are prepared by Messrs. Donkin, Hall, and Gamble with preserved beef, mutton, veal, pheasants, partridges, turtle, callipash and callipee, hams, salmon, oysters, cod, haddock, milk, cream, custards, carrots, peas, turnips, mushrooms, turtle-soup, mock-turtle soup, ox-tail soup, and many other kinds of provisions. Messrs. Ritchie and M'Call, and Messrs. Hogarth, similarly prepare meats, poultry, fish, &c., in canisters. Mr. Broccière has a peculiar method of preparing concentrated forms of food from the blood of cattle. Messrs. Leonard, of Hull, practise a system of preparing, curing and rolling beef, so that it may be kept good for any length of time. Mr. Underwood, of Manchester, has a method of preserving meat which, as he states, "is prepared without salt, and may be kept an indefinite length of time without deteriorating its qualities; when cooked, it retains its nutritious qualities, and eats almost as fresh as recently-killed meat."

In various colonies and foreign countries, too, analogous processes are carried on. In New South Wales and Van Diemen's Land, fresh beef and mutton are excellently preserved for use on ship-board. In New Brunswick, salmon, lobsters, cod, and other kinds of fish are preserved in air-tight canisters; and similar preparations are made in Nova Scotia. M. Baup, of Vaud, in Switzerland, besides one of the many modes of preserving meat and fish in canisters, has a method of bringing meat into such a state that it may be exposed to all the varieties of temperature and humidity in the open air, for many years, without being injured; it is said that this process may be adopted in various seasons, and in various latitudes; and that when the meat so preserved is about to be used, nothing more is necessary than to soak it in water for a certain time, to restore or develope its natural but dormant qualities.

In the long interval of peace between 1815 and 1854, preserved foods were used in regular and moderate quantity; but when the Russian war began, vast purchases were made by the English and French governments, with which the combined fleets in the Black and Baltic Seas were supplied. The rather sudden termination of the war in 1856, left the French government with an enormous supply of unused preserved meats in store; and it was deemed better to sell these by auction, in England, than to keep them for future exigencies. Cans of preserved food formed part of the supplies for the troop-ships during the Indian struggle of 1857-8. All emigrant vessels now include a proportion of similar food among their supplies; the allowance varies from one to three pounds per week for each adult passenger, according to the class of accommodation.

ANTISPASMODICS, from ἀντὶ, *against*, and σπασμὸς, *spasm*, the means of removing spasm. The state called spasm, or cramp, occurs only in muscular structures, and consists in an irregular and often excessive action of particular fibres of a muscle, of an entire muscle, or of several muscles. The muscles of an animal of the higher degrees of organisation, such as man, are divided into two classes, the one set comprising those which are concerned in carrying on the functions most essential to life, namely, the circulation, respiration, and digestion, which act independently of the will, and are therefore called involuntary muscles; the other, which are organs of motion, and subject in a certain degree to the control of the will, are termed voluntary muscles. Each set act in consequence of the application to them of some stimulus; and their action is only uniform or natural when their appropriate stimuli are applied. The heart, for example, contracts from the stimulus of the blood; and the intestines are so constructed as to have proper motions excited in them by the food which we take, and the secretions which are mixed with it; which actions, in the healthy state, go on, not only without our willing it, but also without our consciousness. The stimulus to the other set is either a sensation felt in the part and communicated to the chief nervous centres, namely, the spinal chord or brain, or a spontaneous effort of volition proceeding from the brain, and originating in some thought, and connected with some purpose or design, to be executed by the muscles thrown into action. Of the motion of such muscles we are always more or less conscious, and when the system is in its perfect or usual state of health, we can repeat their action for a considerable length of time, and regulate its degree by repeated and distinct efforts of the will, as when a man walks and quickens or slackens his pace according to his inclination. But a variety of circumstances influence the action both of voluntary and involuntary muscles, and render it irregular. When influenced by any of these, the action of the involuntary muscles becomes sensible and painful, and the voluntary muscles cease to be under the control of the will, and act not only without its stimulus, but often against its consent. These disordered actions would appear to be owing to some improper stimulus, instead of the appropriate one, being applied to the organ or part affected. Venous blood, circulating in the arteries, is productive of great disturbance; and if much of it be conveyed to the brain, it will act as a poison to that organ, for which arterial blood is the natural stimulus as well as source of nourishment. In like manner, there are bodies which, though perfectly mild, such as alimentary substances of difficult digestion, yet excite more violent commotions of the stomach than other substances which are of a very acrimonious nature. Undigested food, or unhealthy secretions in the intestines, excite more disturbance and spasmodic contractions (that is, cholic, in different degrees of severity) than foreign substances, which we might expect to prove very hurtful; such, for instance, as the poison of the viper, which is perfectly innocent when received into the stomach.

Both voluntary and involuntary muscles, and the organs of secretion, are very much influenced by emotions of the mind. Under the influence of hope or joy the heart beats vigorously; while under the depressing passions its action is slow and laborious, and accompanied with such oppression as to have given origin to the phrase, 'a heavy heart.' Fear excites to irregular contraction and relaxation many of the voluntary muscles, whence comes trembling, and produces relaxation of certain muscles, called sphincters, which are usually contracted; it also augments several of the secretions. Grief, when not excessive, increases the secretion of the lachrymal gland, producing a flow of tears; if extreme, it hinders secretion, and forms the state truly characterised by our great poet:

"A misery too deep for tears."

Anger often causes the bile to be secreted in greater quantity, to be altered in its quality, and often absorbed into the blood, thus producing jaundice. The state of mind which may be termed vexation often lessens the secretion of bile, but augments that of the kidneys; and every attack of hysteria terminates in a profuse flow of limpid urine, which is destitute of the usual admixture of bile.

These mental emotions, either directly, or indirectly through the altered and unhealthy secretions, occasion in many persons spasmodic contractions of some muscular organs, which are so violent as to produce alarming and often fatal diseases. Of this, ANGINA PECTORIS furnishes an example; and so powerful are the effects of excessive joy in some instances, that the heart bursting is not a mere figure of speech, and of grief in other instances, that the heart breaking is not a metaphor, but a reality. Many spasmodic actions, such as the cough of hooping-cough, are kept up by habit; others, such as the strange gesticulations of St. Vitus's dance, are acquired from imitation, as stuttering or stammering is occasionally; and both may become a habit, difficult, if not impossible, to lay aside.

What is termed sympathy is even more powerful than imitation, which implies a voluntary adoption of the peculiarities of others: scarcely any persons in company can avoid yawning if one sets the example. Now, yawning is an involuntary spasm of the muscles of the jaw, which is thus propagated through a large assemblage of persons; so hysterical and even epileptic spasms are communicated from one to another, often to a frightful extent, if an individual subject to these complaints suffer an attack in theatres, churches, or private apartments. Such an occurrence is sometimes merely the result of affectation, but more frequently it is the consequence of an irresistible impulse. No one was ever seized with tetanus from witnessing the spasms of a person affected with that excruciating disease; a circumstance which can only be accounted for by observing that in it the mind is in no degree implicated, the mental faculties remaining clear and undisturbed to its termination: and there is reason to believe that in this complaint some inflammation or peculiar state of irritation exists about the origin of the nerves, which no one can induce at will, and which neither primarily nor secondarily happens in the others, which are more strictly nervous affections, that is, merely disorders of the functions of nerves without alteration of structure. The development of tetanus is slow, often not showing any sign of its intended attack till some days after the cause of it began to operate on the system. The others are mostly instantaneous, unexpected, and rapid in all their stages. The impression they make on the bystanders is increased by the surprise felt at their unlooked-for occurrence, often without any obvious or sufficient cause. The more sensitive of those around are therefore most apt to fall into a similar state or train of actions. Of the persons so affected, the greater number will be found to be females. What causes render them more subject than others to such attacks? Females, from the larger size of their nerves, are more *mobile*, as it is technically expressed, that is, more easily operated upon by slight causes than others, and their habits of life and education have often a great tendency to increase this sensibility. Whatever diminishes the strength, whether of mind or body, markedly predisposes to such complaints. The female children of the higher and middle ranks, feeble by birth, are rendered more so by the improper modes of education, physical as well as mental, to which they are subjected. After emancipation from the nursery and school-room, their minds and bodies are further enervated by an injudicious course of reading, and an early devotion to the prevailing habits and usages of fashionable life. Such pursuits preclude the possibility of applying themselves to solid studies, or the acquisition of any knowledge of the human system, and of the necessity of maintaining a regular action of every organ and performance of every function.

By a neglect of one of the most important of the natural functions, that is, regular and complete evacuation of the bowels, the tone of the intestines is lessened. Now, when the muscular fibres of any particular part are under a state of more or less tension than the rest of the system, this is communicated by sympathy to every other part of the body. This is particularly observable in the blood vessels and intestines, both of which are muscular tubes; for a relaxation in any part of these will produce a like affection in every other part of the system. And as irritability and sensibility are very much affected by the degree of tension, a want of it in the vessels constitutes what is called a *nervous habit*, such as is most commonly met with in the female sex, and weak effeminate members of the other sex: such persons will generally be found to be of a costive habit. The peculiarities of the female system have a large share in increasing the disposition to be powerfully acted upon, at times, by trifling causes. Exhausting discharges, to which they are very subject, greatly augment the irritability; and all diseases of a very weakening nature will produce a similar effect in the individuals of either sex: during convalescence from these, a disposition to irregular distribution of the blood exists, and a slight excess sent to one part, or a deficient supply of it to another, will cause disorder of the functions of that part. If it be any portion of the nervous structure which is subjected to these errors, spasmodic action is almost surely the consequence. Nothing is more clear or open to proof, than that convulsive motions result from two opposite conditions of the circulatory system, as relates to the quantity of blood, or rapidity of its flow. An animal while bleeding to death suffers violent convulsions, and an excess of blood sent to the head, or its stagnation in the vessels, will produce the same effect; which, indeed, often follows mechanical pressure of the brain, from a portion of depressed bone of the skull, or from effusion of the serum of the blood, in inflammation of the membranes of the brain. The fullness and distension of the vessels of the brain which precedes apoplexy often occasion vomiting, which is a convulsive action of the stomach and some other muscles, and is a warning sign, often unhappily neglected, of the approach of this disease. The more extensive and violent convulsions of epilepsy are, in all probability, the result of a temporarily deranged state of the circulation within the brain, as the loss of consciousness at the time of the attack, the progressive impairment of the intellectual powers, and the usual termination of the disease in apoplexy, palsy, fatuity, and death, attest.

The nature of the causes of the different diseases of which spasm forms, in general, a feature, the complication of these with other diseases or morbid states, and the manner in which each terminates, should all be taken into consideration, if we hope to make a beneficial selection of a remedial agent from among the number of antispasmodic medicines. But such a judicious preliminary measure is rarely adopted; and these articles are often administered in a manner truly empirical, by many professional as well as all unprofessional persons. A brief review of the diseases in which antispasmodic medicines are employed, and which agree only in having spasm for one of their symptoms, while they often differ widely in their causes, nature, and termination, will convince every one how needful is a knowledge of these points to guide us in the choice of the means of cure. The following is not given as a perfect classification or even as an approximation to one, but is merely intended to show the diversified nature of spasmodic diseases, and to furnish an argument for caution in the management of them. The treatment must vary greatly, according as the particular disease is attended with inflammation or not, or according as there is a risk of its occurring, either in the natural progress of the disease, or in consequence of the employment of improper means of treatment. The selection of remedies must be determined also according to the stage of the complaint, and according to the mode in which it is connected with the state of the mental faculties, or its tendency to involve these in the train of morbid actions, if it be not cured before such a calamitous termination take place. Keeping these points in mind, we may arrange spasmodic diseases, in some degree, as follows:

Unattended with inflammation, primarily, or disturbance of the mental faculties:

Simple Cramp. Cholic.—These generally proceed from some undigested substance, or hardened fæces, irritating the bowels: but in the latter disease inflammation is apt to come on; and in the worst forms of cholic, called Ileus, or Iliac-passion, and painter's cholic, it seldom fails to supervene, and then becomes the chief source of danger, as well as most important object of the treatment.

Diarrhœa, or simple looseness, and Cholera.—In these the cramps or spasms are never the first signs, but seem to result from the exhaustion occasioned by the profuse liquid discharges. Inflammation may occur during, or from, diarrhœa, and fever is the most common consequence of cholera, that is, of epidemic cholera; the occurrence of which in either case must lead to a modification or alteration of the plan of treatment.

Angina Pectoris. Asthma.—Affecting the organs of respiration and circulation.

Attended with inflammation, primarily, but causing no disturbance of the mental faculties:

Dysentery.—Affecting the organs of digestion.

Croup, Hooping-cough.—Affecting the organs of respiration.

Unattended with inflammation to an appreciable degree—perhaps in no degree:

Hysteria.—Not affecting the mental faculties, except the volition.

Chorea, St. Vitus's Dance.—Unattended with loss of consciousness; and—

Epilepsy.—Attended with loss of consciousness.

These two diseases sooner or later affect the mental faculties, and have a tendency to a common termination, namely, fatuity, unless they subside spontaneously, or are cured by medical treatment. Chorea generally originates from, or is connected with, accumulations of the bowels, and epilepsy frequently from a similar irritation of these parts, such as worms, but its causes are numerous, and its cure, in most cases, difficult.

Spasmodic diseases, of an obscure nature, chiefly affecting the organs of respiration:

Tetanus and Lock-jaw. Hydrophobia.—These may at some period become attended with inflammation, or rather fever; but this appears to be the result of the constant suffering, and is seldom the direct cause of death, which seems to be the consequence of that depression of the heart's action which long-continued pain or unpleasant sensations produce.

Diseases in which inflammation is the primary affection, spasm the secondary:

Inflammation of the Brain—acute, *Phrenitis*.

Acute or chronic, *Hydrocephalus*, that is, *Water in the Brain*, occurring mostly in children of a scrofulous habit.

Fever.

The treatment of these diseases is as diversified as their causes, and, to be successful, requires a degree of judgment and knowledge which few possess. To comprehend the nature of those spasmodic diseases which are unaccompanied by inflammation, and for which anti-spasmodic medicines are chiefly employed, we must be made aware that, in the human system, there are two distinct sets of nerves, having different origins, and fulfilling separate functions; the one set are called nerves of sensation, the other nerves of motion. The former receive impressions and convey the sensations from all parts of the body *to* the brain; the latter execute the dictates of the brain, by conveying an impulse *from* it to the organs of motion. The organs of motion—that is, the muscles—are so adjusted, and in the healthy state so equally supplied with nervous energy, as precisely to balance or antagonise each other [ANTAGONIST MUSCLE]; and one muscle, or set of muscles, can only overbalance another, or several muscles, when it receives an additional supply of nervous energy from an effort of volition. Thus the hand is opened and shut at will: when opened, the extensor muscles overpower the flexor muscles; when shut, the flexor muscles overpower the extensors.

In diseased conditions of the nervous system, this fine balance is lost from various causes: the nerves of sensation may become preternaturally sensitive; the nerves of motion may become paralysed; the power of voluntary motion may be perverted in various ways and degrees; the flexor muscles, independent of volition, may overpower the extensors, or the extensors the flexors. When affected with tetanic spasm, the extensor muscles of the back of a delicate girl could not be replaced in the natural state of equilibrium by any effort of the will, nor by a weight of eight hundred pounds; and under the influence of hysterical or epileptic excitement, a delicate person cannot be controlled by three or four robust men. The action of the muscles is so violent that the fibres are sometimes torn across, or even the bones fractured.

Some of these spasmodic diseases give, at times, an intimation of their approach, generally by a peculiar sensation being experienced in some part of the body—often the thumb in epilepsy, or between the stomach and throat in hysteria; the spasmodic actions not commencing till these sensations have reached the brain. At other times no warning sensation is felt; yet often, on careful examination, some tender spot will be discovered, of which the patient was not in the least degree previously aware. In hysteria this tenderness is generally felt at some point along the course of the spine or back-bone; and in no case of spasmodic disease should we ever omit a minute examination of this part. Should drawing the finger along the course of the spine, and making firm pressure as we proceed, not reveal its existence, a sponge, dipped in water as hot as can be borne, will, in its progress along the spine, cause the patient to start when it reaches the tender spot. The discovery of this will often furnish a key to all the strange symptoms and spasmodic actions, as well as explain the capricious conduct, of the sufferer, which has alarmed the friends and puzzled the medical attendant. When appropriate treatment is directed to this point, most of the troublesome symptoms abate, or cease altogether.

As most spasmodic diseases, especially if connected with affections of the mind, have a great tendency to recur and become habitual, it is of the utmost importance to stop them at an early period.

The remedies which have been found most efficacious in stopping or preventing these, are either such as make strong and new impressions on the organs of sense, and thereby diminish the effect of sensations already existing, or such as blunt the sensibility in general, and thereby diminish all effects of sensation; or else such as raise the whole of the system to a level with the part spasmodically excited, and so establish the equilibrium, from which forced state all muscles may simultaneously subside.

The fibres of each muscle act generally in concert: if a few act independently of the others, these are in a state of cramp. Particular sets of muscles act in concert, as all the flexors, or all the extensors; one or more of these acting independently of the rest cause spasm. Now we often relieve this by calling the others into action; and as volition simply is not equal to this, we use mechanical or medicinal means. Cramp of the limbs is often removed by pressing the toes or fingers against a resisting body, by which all the muscular fibres are brought to the same level. This example of a mechanical process is the only one worthy of mentioning, and is applicable both in slight cases, as cramp of the limbs is generally merely a symptom of some internal derangement of the bowels, of the spinal chord, or of the brain, and also in the severe cramps of cholera.

The medicinal means constitute the antispasmodic remedies, and are of different kinds. Very few articles are, strictly speaking, merely antispasmodics; that is, used solely to allay spasm, and incapable of being employed for any other purpose. On the contrary, this is only a particular application of substances capable of serving other and more general ends. Consequently, many of the so-called antispasmodics belong to other classes of medicines, such as the stimulants, particularly diffusible stimulants, as alcohol (brandy), sulphuric ether, camphor, &c.; or to the narcotics, such as opium, belladonna, &c., or to the tonics, such as metallic salts, namely, of iron, zinc, and silver; or vegetable bitters, as cinchona bark. The first set, or stimulating antispasmodics, act, apparently, by rousing the nervous energy of the system, and raising the neighbouring muscles to a level with the part in a state of spasmodic excitement. The second set act by rendering the nervous system torpid, and insensible to every sensation; in large doses producing complete insensibility, even to the extent of coma and death. These two are administered when an attack is threatened or actually begun; the tonics are administered while the patient is free from an attack, and act by strengthening the system, so as to render it less susceptible of being acted upon by slight causes, particularly the irritating cause, known, or supposed, to excite the paroxysm or fit. The substances which are more especially considered as antispasmodic are volatile oils, such as mint, lavender, &c., derived chiefly from the tribe of the *Labiatæ*; or cajeput oil, from *Myrtaceæ*; or dill, anise, fennel, &c., from the *Umbelliferæ*, from which tribe also are derived the fœtid gums, as they are improperly termed, being gum-resins, such as assafœtida, galbanum, &c. These, with valerian and myrrha from the vegetable kingdom, and musk and castor from the animal kingdom, are the most valuable antispasmodics. All the volatile oils seem to act in the same way as the purely stimulating antispasmodics; while the fœtid gum-resins act by substituting new and powerful sensations instead of the morbid ones, and must be administered generally when the attack is threatened or begun.

These kinds of antispasmodics differ in value, not only as relates to their mode of action, but to their safety. The stimulating antispasmodics are only admissible when a fit is threatened, or may have begun; and as they greatly excite the vascular system—that is, quicken the circulation—if upon their being given once they fail to remove the spasm, they should not be repeated. This caution is more especially necessary in respect to brandy, which is too commonly resorted to on every threatening or attack of spasm, such as cholic. So many of these diseases being connected with, or disposed to end in, inflammation, the free use of brandy, or other stimulant, is decidedly injurious. The inflammation in croup, hooping-cough, and dysentery must first be removed by appropriate means, when the spasm will generally subside or disappear entirely: if it should remain, in hooping-cough, in a great measure from mere habit, antispasmodics may be used, but even then the narcotic antispasmodics, such as Prussic acid, paregoric, or henbane, are to be preferred. The propriety of employing belladonna extensively in this disease is very questionable. The external employment, in the form of embrocations, of the stimulating antispasmodics, is more allowable in cholic or hooping-cough; but here they act on a different principle, namely, that of counter-irritation. This is, in itself, a most valuable means of curing spasmodic diseases. An irritating application to the spine is of much service in hooping-cough: tartrate of antimony ointment or plaster [ANTIMONY] applied to the tender spot, which we have said often exists in hysteria, and other similar diseases, will be productive of more good than all the antispasmodic medicines which can be tried. Stammering, or other difficulties of speech, might be materially diminished by repeated irritating applications, as blisters, tartrate of antimony ointment, &c., to the nape and sides of the neck. Severe hiccup, continuing for several days, and which resisted all internal remedies, has yielded to a blister applied along the side of the neck. Every physiologist will understand how this happens.

The means which may be employed to intercept the passage of the peculiar sensation to the brain are merely mechanical: for example, tying a string tightly round the thumb prevents the *aura epileptica*, in epilepsy, reaching the brain, and wards off the attack. A cupping-glass would answer as well if applied to any large spot whence the sensation arose.

Free scarification of the gums in children, when teething, is much more efficacious in allaying convulsive affections than internal medicines, except mild purgatives.

The medicines which may be administered while the patient is free from a fit, or in the intervals of the paroxysms, are much more likely to effect a cure than the others. These are tonics and purgatives. For the reasons already stated, purgatives are of primary importance, as they unload the bowels, improve the secretions, and impart vigour to the whole muscular system. Many cases of severe spasmodic disease have been cured by the use of purgatives only, and none can be cured without their free and daily use for some time. (See Hamilton on 'Purgative Medicines,' sixth edition.) Aloetic purgatives are, in general, the best; but where, as in epilepsy, there is reason to suspect the existence of worms, oil of turpentine is to be preferred.

After purgatives have been administered for some time, should the disease not have yielded, metallic or vegetable tonics may be employed with great advantage, particularly in hysteria, chorea, epilepsy, and stammering. In hysteria, chorea, and stammering, the preparations of iron are, in general, best; in epilepsy, preparations of zinc, of copper, but above all of silver, are preferable: sulphate of quinine is also very serviceable.

For the cure of hydrophobia, or tetanus, nothing has yet been found to succeed. There is some reason to hope that, for tetanus, a powerful vegetable compound from South America, called the *woorali*, may be beneficial, if we may judge by its effects on animals affected with tetanic spasm.

Several of the diseases of which we here speak being connected with mental emotions, and some of them originating from imitation or being kept up by habit, mental agency has sometimes been employed to effect a cure, and occasionally with success.

Upon a threatened attack of hysteria or epilepsy, the powerfully attracting the mind to a different object than that which occupies the attention of the patient may ward off the fit. But this requires great judgment and discretion. Formerly the most disgusting means were resorted to, and the sufferers were made to swallow animals of a forbidding kind, or other equally repulsive measures were tried. These cannot be too much reprobated; and we should bear in mind that chorea, or epilepsy, may be brought on by a sudden fright. The separation of a person subject to chorea, or hysterical and epileptic fits, from among others, is often necessary; and when we know that the spasmodic actions are the effects of imitation, the employment of fear may be justifiable; but in any other case it would be criminal to have recourse to it, and thereby, perhaps, add a mental disorder to a bodily one, already sufficiently afflicting.

Our endeavours to lessen the tendency to nervous diseases will be most successfully directed to regulating the education, physical and moral, of children, especially of female children. This subject has been already treated of under the article AGE, to which we refer.

ANTI'THESIS, a Greek word literally signifying 'opposition.' It is used in various senses by the Greek writers: sometimes it means merely 'objections,' or 'opposite arguments;' sometimes it is used to denote the contrasting of one set of circumstances with another; as for instance, when an orator or other person attempting to place the conduct of an adversary in the worst light, first states what the accused *ought* to have done, and then what he *has* done.

But the term antithesis is most commonly used to express contrast of ideas; and the term is equally applied whether the contrast is effected by single words, or by single clauses. (See Quintilian, 'Inst. Orat.,' lib. ix. cap. iii.) The following example from the oration of Demosthenes against Æschines, entitled the Crown, is, in part quoted by Demetrius Phalereus (Treatise Περὶ Ἑρμηνείας, § 262), and by Hermogenes; it is a sample of antithetical invective, in which Demosthenes attempts to show his superiority over his opponent:—"You were employed in teaching, but I was taught: you were a mere menial in the service of religion, but I participated in the sacred rites: you were one of the chorus, but I was the choragus (director of the chorus): you were a petty clerk, but I was a public speaker: you were an actor and played a third-rate part, but I was a spectator; you failed in your part, and I hissed." This taste for antithesis shows itself very strongly in the Greek language, both in poets and prose writers, and more especially in some of the orators and rhetoricians; but it is generally and justly condemned by the Greek writers on style. The antithesis does not necessarily imply contrariety between the things which are brought together; for example, one of the rhetorical exercises of Gorgias, entitled the 'Encomium of Helen,' begins with the following antithesis:—"The ornament of a state is the courage of its men; of the body, beauty; of the mind, wisdom; of action, virtue; of words, truth." Quintilian (ix. 3) expresses the Greek term ἀντίθετον (which is equivalent to ἀντίθεσις) by the Latin word *contrapositum*; and he remarks, that the antithesis does not always contain contrarieties or opposites. He gives the following example from the rhetorician Rutilius: "To us first the immortal gods gave the fruits of the earth: what we alone received, that have we diffused over the whole earth. To us our ancestors transmitted a commonwealth: we have rescued from servitude our allies also." Cicero has the following example of antithesis, which may be compared with similar examples in our own language:—"Quod scis, nihil prodest: quod nescis, multum obest," which may be very imperfectly translated—"What you know, does no good; what you do not know, does much harm." When antithesis is used sparingly and judiciously, it sometimes gives force to expression, and helps to fix distinctions in the memory; but its frequent and indiscriminate use tends to draw the mind from a true perception of the subject, and to fix it on the play of words more than on the real meaning of the sentence.

A'NTLIA PNEUMA'TICA, the air-pump, a constellation in the southern hemisphere, named by Lacaille. It is bounded by Centaurus, Crater, Hydra, Pixis Nautica, and Argo. The following is a classified enumeration of its principal stars:

Magnitude.	Number of Stars.
4·5	1
5·5	6
6·	22
	29

Hence the number of stars visible to the naked eye in this constellation amounts to twenty-nine.

ANTŒCI, from the Greek, signifies those who live over against each other, and is applied to designate the inhabitants of two places which have the same longitudes and latitudes, only differing in one latitude being north and the other south. For example, Malta and the Cape of Good Hope are nearly antœci. Two antœcial places have the same hour of day or night, but opposite seasons of the year.

ANTONINE COLUMN, a lofty pillar which stands in the middle of one of the principal squares of the city of Rome. It was raised by the senate in honour of the emperor Marcus Aurelius Antoninus, and in memory of his victory over the Marcomanni and other German tribes. It was one of the principal ornaments of the Forum of Antonine. In an inscription which has been found near it, and which is now in the Vatican, it is styled 'Columna centenaria Divi Marci.' It was also called 'the greater Antonine column,' to distinguish it from another and a smaller one, made of a solid piece of granite, which had been raised in honour of Antoninus Pius. (Nardini and Nibbi, 'Roma Antica,' and Vignola, 'De Columna Antonini Pii.') During the ages of barbarism which followed the extinction of the western empire, this pillar, and especially its pedestal, suffered greatly from the hands of the various invaders, as well as from the fires which frequently occurred at Rome; the historian Poggio says also from lightning. Pope Sixtus V. repaired it at the expense of 10,000 scudi, and placed the inscription which is now seen on the pedestal, the original one having been probably defaced. He also raised on the summit of the pillar a bronze statue of St. Paul: that of Marcus Aurelius, which formerly stood there, had been removed it is not known when or by whom. The shaft of the pillar is 13 feet 1 inch in diameter at the bottom, and 1 foot less at the top; its height, including the pedestal and capital, is 136 feet, of which 13 are under ground; and the statue on the top and its pedestal are 27½ feet more, making the whole height 163½ feet, (Taylor and Cresy's 'Architectural Antiquities of Rome.') The pedestal of the Antonine column is disproportionate to the shaft. The capital is Doric. The shaft is made of 28 blocks of white marble placed one above the other, a spiral staircase of 190 steps is cut through the interior of the marble, and leads to the gallery on the top, which is surrounded by a balustrade. The exterior of the shaft is covered with bassi-rilievi placed in a spiral line around, which represent the victories of Marcus Aurelius over the Marcomanni and other hostile nations. The style and execution of these sculptures are inferior to those of the Trajan pillar, which the artists evidently purposed to imitate. The sculptures of the Antonine column have been engraved by Santo Bartoli, and illustrated by Bellori. The pillar itself is still one of the most striking monuments of ancient Rome, and one of the principal ornaments of the modern city. It has given to the square in which it stands the name of Piazza Colonna.

ANU'BIS, or **ANUP**, an Egyptian deity, represented with the head of a fox, dog, or jackal, and a human body. In some Egyptian remains we observe him standing by a bier, on which a mummy is lying. The dog was worshipped by the Egyptians, as we are told by Herodotus; and Anubis came to be represented as a symbolical or astronomical character. Anubis was the son of Osiris and Nephthys, the wife of Typhon, and sister of Osiris, and is represented as holding the balance to ascertain the good and evil of the judged before the throne of Osiris, sometimes in company with Horus, and sometimes alone. He appears to have been considered in one sense as the conductor and guardian of departed souls ("the embalmer of the dead, and watcher of the gate of the sun's path"), and in this respect his functions bear some resemblance to those of Hermes of the Greeks, and Mercurius of the Romans. He was placed in the front of the Egyptian temples, in the dromos or line of sphynxes leading from the entrance to the sacred enclosure, as a guard to the other gods: "This is the sacred dromos of Anubis," says Callimachus. He is not mentioned by any Roman writer before the time of Augustus; but his worship must have been introduced towards the end of the republic, as is shown by Appian in his description of the escape of M. Volusius, the ædile ('Bell. Civ.' iv.); and it spread widely under the empire, both in Italy and Greece. Other resemblances are suggested between this Egyptian deity and Hermes (the god with the golden wand, χρυσόῤῥαπις), by the supposition that the element *Anub*, in Anubis, has the same signification as the Coptic *noub* (see Coptic version, Matt. ii. 11), signifying gold.

(Jablonsky, *Panth. Ægypt.* Anubis; and Champollion, *Panthéon Egyptien.* For the phonetic name of Anubis as son of Isis, see Salt's *Essay*, &c., pl. iii.)

ANUS, DISEASES OF. One of the most frequent diseases of this part of the body is that which is commonly known by the name of Fistula, or *Fistula in Ano.* This disease consists of a fistula or sinus by the side of the rectum. It sometimes opens externally, without communicating with the bowel, and is then termed blind external fistula. It more frequently communicates with the bowel, without opening externally, and is then called blind internal fistula. Usually, however, these sinuses have an opening internally and externally, and the disease then constitutes complete fistula. In this latter form pus, flatus, and fæculent matter, are discharged from the openings. It is accompanied by heat of the parts, great discomfort, and sometimes pain and spasm of the sphincter muscles. It is sometimes attended with acute inflammatory symptoms, and the general health suffers.

When this kind of abscess occurs, the healing is prevented by three circumstances:—1. The fistulous condition of the cavity. 2. The presence of foreign matters. 3. The frequent motion of the part by the action of the neighbouring muscles.

This disease originates most frequently in the interior of the bowel by a small ulcer, which, extending, at last produces a second opening. It is often found in persons labouring under pulmonary consumption, and its persistence and inconvenience are increased by the constant cough which accompanies that disease.

The treatment of fistula is simple, and usually very successful. By laying open the whole of the sinus and dividing the sphincter, the two main obstacles to the cure of this disease are removed. The mode of operating in this case is simple. A grooved probe is introduced into the external opening until it passes out at the internal opening. A probe-pointed bistoury is then introduced along the groove, and the sinus is laid open through its whole length. Usually no important vessels are divided in this operation, so that all that is necessary after is to introduce a slight dressing of lint. An opiate should be given after the operation.

Hæmorrhoids or *Piles* consist of an enlarged condition of the veins supplying the anus and rectum. This disease is divided into two kinds, external and internal. It seldom occurs before puberty, and is more common in females than males, and in the rich and luxurious, than in the poor and hard-worked. This arises from the fact that whatever tends to determine blood to the lower part of the rectum, and to retard the return of blood from that part, favours piles. Thus they come on in pregnant females, in persons troubled with habitual constipation, abdominal tumours, obstructions in the portal system of veins, and in those who lead sedentary lives or who feed too well.

External piles consist of a congeries of varicose or enlarged veins, which are surrounded by a condensed and enlarged connective tissue, and are covered partly by mucous membrane and partly by loose rugose integument. The parts are sometimes inflamed, at other times free from any capillary derangement. The mucous or rugose surface occasionally becomes ulcerated. It is under these circumstances that the coats of one or more of the veins give way, and they bleed to a greater or less extent. When this does not take place they do not bleed. These two states are called respectively *bleeding* and *blind* piles.

The treatment of this form of piles may be either palliative or radical. The radical cure consists in removing the parts either by the scissors or bistoury, and leaving them to heal in the ordinary way, or a ligature may be passed round the enlarged vessels, and the strangulated part left to slough off. When this operation is not thought desirable, much may be done to relieve the enlargement and pain of piles by a palliative treatment. Whatever will remove the loading of the vessels in the lower part of the bowels will relieve them. Thus parturition removes them when caused by pregnancy. If the part is inflamed, rest, purgatives, poultices, and anodyne applications may be had recourse to. Astringent applications combined with opium may be applied, as gallic and tannic acids. The purgatives most to be recommended are castor oil, or an electuary with the confection of senna, sulphur, and cream of tartar. In cases where the liver is affected, the state of this organ should be specially attended to.

Internal piles, are of three kinds: 1. Varicose veins surrounded by enlarged connective tissue, and covered by mucous membrane, and bleeding or blind. 2. Tumours of the nature of sarcoma. 3. A congeries of blood-vessels resembling erectile tissue, and occurring in the submucous connective tissue. This last form is the most common. They may protrude from the anus or not. When they do not, they descend occasionally when the bowels are acted on, and become very troublesome till they are returned. If not replaced they become constricted and inflamed or bleed. In these cases bleeding usually occurs when the bowels are acted on. When the tumours are replaced, no great inconvenience occurs. If, however, the bleeding continues, the patient becomes pale, thin, and weak; noises in the ears, giddiness, and palpitation of the heart come on, in fact all the symptoms of anæmia set in.

The treatment in this case may be either palliative or radical. Frequently the latter course should at once be had recourse to. The internal tumours are seldom of a kind to allow of removal by the knife, and ligature is by far the safest process. When the base of the tumour is small, it may be pulled down by a tenaculum and a single ligature placed round it; but when the base is broad, a needle with two ligatures is passed directly through the tumour, and a ligature is tied round each half of the tumour. This operation is very painful and difficult, and wherever circumstances will admit, is greatly facilitated by the use of chloroform. After the operation, opiates should be given.

Nitric acid has been recently recommended in these cases, but unless the tumours are small, and the cases slight, this remedy is liable to fail, and after the infliction of much pain the operation must be had recourse to.

Should the palliative treatment be had recourse to, all those points to which reference has been made under the head of external piles, must be attended to. Astringent remedies and opiates must be injected into the bowels. The bowels must be regulated, the liver looked to, and when the hæmorrhage is considerable, gallic and tannic acids, with acetate of lead, must be given internally.

Prolapsus Ani is a very frequent and troublesome affection of the lower bowels. In consequence of relaxation, the rectum passes down, and becoming averted protrudes itself beyond the anus. This protrusion may be either *partial* or *complete.* It is called complete when the entire bowel comes down, and partial when the mucous coat alone descends. The latter is the most frequent, and sometimes accompanies internal piles. Children and old persons are more liable to the complete form. The quantity of bowel or membrane which passes down varies in size, from a mere annular enlargement to a tumour as large as a child's head. It is sometimes accompanied with inflammation, and the mucous membrane throws off a coloured discharge. Great pain and uneasiness are often felt, and general languor and debility are present.

The treatment is either palliative or radical. When this disease depends on general constitutional weakness, tonics, change of air, and a proper regimen will restore the patient to health. The bowel should always be returned as speedily as possible, and this may be done by proper pressure after lubricating the parts. When they are inflamed, leeches should be applied and rest secured before attempting reduction.

The radical cure is effected by removing one or more of the redundant folds of the mucous membrane by the knife or ligature. The cicatrix thus formed contracts and sustains the replaced parts, or the bowel may be left intact, and a portion of the redundant external integument may be removed, which by its subsequent contraction prevents the painful protrusion.

Imperforate Anus.—Children are occasionally born without an anal orifice. Three forms of this malformation are described:—1. The rectum may be fully developed, and have its orifice closed by an external membrane, or a septum may be developed at some distance from the orifice. In the treatment of this form of imperforate anus, nothing more is required than an incision through the occluding membrane. 2. The rectum terminates at some distance from the perineum, and there is a mere depression where the anal orifice ought to be. This is the most common form. It requires a more serious operation than the last. The meconium should be allowed to accumulate, and pressure being made on the abdomen, an incision must be made down to the bowel, and a passage thus established. 3. In this form the rectum is very deficient or altogether absent. An operation like the last may be performed, and failing this, an attempt may be made to form what is called an *artificial anus.* This operation is performed not only for imperforate anus, but in cases where, from tumours, or the impaction of foreign matters, the fæcal matter does not find its way to the anal orifice. The sigmoid flexure of the colon is the part which is preferred for this operation. It may be reached from before or behind. The former is the easiest operation; the latter is the most convenient position for the new opening to the patient. In performing the latter operation, an incision is made midway between the last false rib and the crest of the ileum. The colon is then secured, an incision made into it, and the edges of the bowel brought in contact with the external wound by means of ligatures. This operation has been successfully performed in cases of non-malignant tumours and other causes of the impaction of the lower bowel. In children with imperforate anus however it seldom succeeds, as other malformations often exist which speedily terminate the life of the patient.

APANAGE (*Apanagium, Apanamentum*), the provision of lands or feudal superiorities assigned by the kings of France for the maintenance of their younger sons.

The prince to whom the portion was assigned was called the *apanagist;* and he was regarded by the ancient law of that country as the true proprietor of all the seigniories dependent on the apanage, to whom the fealty (*foi*) of all subordinate feudatories within the domain was due, as to the lord of the "dominant fief."

Under the first two races of kings, the children of the deceased monarch usually made partition of the kingdom amongst them; but the obvious inconvenience of such a practice occasioned a different arrangement to be adopted under the dynasty of the Capets, and the crown was permitted to descend entire to the eldest son, with no other dismemberment than the severance of certain portions of the dominions for the maintenance of the younger branches of the family. Towards the close of the thirteenth century, the rights of the apanagist were still further circumscribed; and at length it became an established rule, which greatly tended to consolidate the royal authority in that kingdom, that, upon the failure of lineal heirs male, the apanage should revert to the crown.

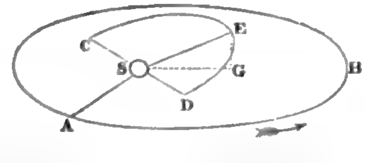
The period at which this species of provision was first introduced into the law of France, the source from which it was borrowed, and the origin and derivation of the term itself, are matters on which the historical antiquaries of France seem not to be agreed. (See Pasquier's 'Recherches,' lib. ii. cap. 18, lib. viii. cap. 20; Calvini, 'Lex Jurid., Appanagium;' Ducange, 'Gloss., Apanamentum;' Pothier's 'Traité des Fiefs;' and Henault's 'Hist. de France,' Anno 1283.)

By a law of 22nd November, 1790, it was enacted, that in future no appanage *real* should be granted by the crown, but that the younger branches of the royal family of France should be educated and provided for out of the civil list until they married or attained the age of twenty-five years; and that then a certain income called *rentes apanagères* was to be granted to them, the amount of which was to be ascertained by the legislature for the time being.

"It is evident," says Mr. Hallam, "that this usage, as it produced a new class of powerful feudatories, was hostile to the interests and policy of the sovereign, and retarded the subjugation of the ancient aristocracy. But an usage coeval with the monarchy was not to be abrogated, and the scarcity of money rendered it impossible to provide for the younger branches of the royal family by any other means. . . . By means of their apanages and through the operation of the Salic law, which made their inheritance of the crown a less remote contingency, the princes of the blood-royal in France were at all times (for the remark is applicable long after Louis XI.) a distinct and formidable class of men, whose influence was always disadvantageous to the reigning monarch, and, in general, to the people." ('Middle Ages,' vol. i. p. 121, 2nd edit.)

APELLEANS, or **APELLITES**, a sect of heretics so called from their founder Apelles, who lived about the middle of the second century, and had been originally a disciple of Marcion. The belief of the Apelleans appears to have been a variation of that of the Marcionites; and both took their rise from the Gnostics. They are said to have, as well as the Marcionites, held the Manichæan dogma of the good and evil principles; but what principally marked them was their doctrine upon the subject of the incarnation of Jesus Christ. They said that his body was neither real, as commonly supposed, nor only apparent or shadowy, as Marcion taught; that it was formed not of flesh and blood, but of air, and that, as it had been received in his descent to the earth, so it was cast off and dissolved again into air in his ascent to heaven. Besides thus denying that Christ took his body with him to heaven, they also denied the general doctrine of the resurrection of the body. They are accused moreover of denying the authority of the Old Testament. Apelles and his heresies are mentioned by Augustine, Epiphanius, Tertullian, and Eusebius. [HERESY.]

APHE'LION, from the Greek ἀπὸ, *from*, and ἥλιος, *the sun*, means that point of a planet's orbit which is farthest from the sun. Its opposite point is the PERIHELION, from περὶ, *near to*, and ἥλιος, *the sun*, which is the nearest point to the sun.



Let S represent the sun, S A B the earth's orbit, or plane of the ecliptic, and S A a parallel to the line in which the earth's equator cuts the ecliptic, from which line all heliocentric longitudes (that is, measured round the sun) are measured in the direction of the earth's motion, represented by the arrow. Let C D E be a part of the orbit of a planet, S E the longest line which can be drawn through S, then E is the aphelion of the planet. If a plane S E G be drawn perpendicular to the ecliptic, the angle A S G is the heliocentric longitude of the aphelion E.

The supposition of the planets moving in elliptic orbits round the sun is not true, unless the ellipses themselves be supposed slowly to change their positions and figures. In all the planets, except Venus, a very little more than a complete revolution must be made between two aphelia; in Venus, on the contrary, a little less. This inequality is represented by saying, that the aphelia of all the planets, except Venus, slowly increase in longitude, while the aphelion of Venus decreases. The apparent motions of the aphelia are greater than the real, since the line S A moves slowly backwards. [PRECESSION.] The apparent annual motion of the aphelia is the annual precession of the equinoxes, together with the real annual motion, except in the case of Venus, in which the apparent motion is the precession of the equinoxes *diminished* by the real motion. The apparent motion of the aphelion of Venus is like that of all the others, in the direction of the earth's motion, for though the aphelion of Venus moves backwards, the line S A does the same at a greater rate.

A'PHORISM (ἀφορισμὸς), literally "a limitation," or "a fixing of limits," and hence used by the Greek writers to express a short sentence, containing a moral precept, or a rule of practice, briefly and forcibly expressed. The term has been adopted in medicine; for instance, both Hippocrates and Boerhaave have written books entitled 'Aphorisms,' containing medical maxims, not treated argumentatively, but laid down as certain truths. For example, "Neither repletion nor hunger, nor anything which exceeds natural limits, is good." The word is similarly used in the civil law. We give the following as specimens of moral aphorisms.

"It is always safe to learn from our enemies; seldom safe to instruct, even our friends."—*Lacon.* "He will easily discern how little of truth there is in the multitude; and though they are sometimes flattered with that *aphorism,* will hardly believe the voice of the people to be the voice of God."—Brown's 'Vulgar Errors,' book i. 3.

Sayings of this description are well adapted to make an impression on the memory; but they tend to substitute authority instead of judgment as the motive of action, and may therefore be as well applied to maintain prejudices as to assert truths; to impose conventional and needless restraints, as to furnish safe rules of conduct to the inexperienced. It is with reference to this that Milton uses the word. "There is no art that hath been more cankered in her principles, more soiled and slubbered with *aphorisming* pedantry, than the art of policy."

APHRODI'TE, the goddess of love and beauty. According to Homer, she was the daughter of Zeus and Dione, one of the Nereides, or ocean nymphs: a later legend, told by Hesiod (*Theog.* 188), relates that she sprung from the foam of the sea, produced when Kronos threw into it the amputated members of his father Uranos. There was a celebrated picture of her rising from the sea (ἀναδυομένη), esteemed the master-piece of Apelles. She first came to land at the island of Cythera, and thence proceeded to Cyprus. These islands were her favourite places of resort, and many of her epithets are derived from them (Cytherea, Cypris, Paphia, &c.). She was regarded as the most beautiful of the female deities. To her, according to a legend which has been at all times a favourite with artists, for the opportunities it affords of representing varied types of female loveliness, the prize of beauty was awarded by Paris. Aphrodite was assigned in marriage to Hephæstus (Vulcan) the god of metallurgy, and there is a well-known tale of her detection in an amour with Ares (Mars) ('Odyss.' viii. 266). Hermes and Poseidon (Mercury and Neptune) were also among her favoured suitors. Her amours, however, were not confined to the gods. For her adventures with Adonis, see that article in the BIOGRAPHICAL DIVISION, vol. i. col. 42: she also bore Æneas to Anchises, a youth of the blood royal of Troy, as is largely related in the Hymn to Aphrodite, ascribed to Homer. In the Trojan war she was ranged with Apollo and Ares on the side of the Trojans, and in attempting to protect her son Æneas, was wounded by Diomed. According to the fictions of the 'Æneid,' she continued to extend her maternal care over Æneas, and brought about his establishment in Italy, and through him the Julian family derived their descent from her. To the Italians she is known by the name of Venus; a goddess, probably, of indigenous origin, but so confounded in the fictions of poets and mythologers with the Greek Aphrodite, that her original attributes have nearly disappeared.

It is supposed that the worship of Aphrodite was introduced into Greece from Syria, and that she is identical with the Phœnician goddess Astarte. It is certain that she was from the earliest times regarded as the goddess of natural fertility—the great goddess of nature, the mother of all living beings. In the ancient temples of Cyprus she was adored under the form of a conical stone. When a human form was adopted, the Grecian artists represented her as a consummately beautiful woman; but she was not represented undraped in the earlier and more devotional periods of Hellenic art. Usually she was represented enthroned and surrounded with the emblems of fertility; either fully clothed or with one breast uncovered. This last was the characteristic manner throughout the Phidian era. Up to this time Aphrodite was regarded as the protectress of virtuous love. The age of Praxiteles, a period in Greek art corresponding to the sensuous epoch of the Medici in Italian art, initiated a more voluptuous conception. Aphrodite was associated with sexual passion—the goddess of love and beauty. The religious feeling having died out among the cultivated classes, artists saw in Aphrodite only a vehicle for the representation of the most perfect beauty in the female form. The goddess was now usually represented wholly undraped, or with a robe drawn round the lower part of the body. A very common mode was to represent her either about to enter or leave the bath, the position being such as to represent feminine modesty or shame. It was upon these representations of the undraped Aphrodite that the greatest of the Greek sculptors and painters exerted their very highest skill. Such was the famous Cnidian Venus of Praxiteles. It is related that the great sculptor having been commissioned by the inhabitants of Cos to make them a statue of Aphrodite, executed two; one draped according to the prescribed form, the other nude. The latter was infinitely the more beautiful; but they chose the former, as more consistent with their notion of their deity. The naked statue was, however, eagerly purchased by the inhabitants of Cnidus, who built for its reception a temple open on all sides; and so great became its renown, that strangers flocked to the island from all parts of Greece to see it. Nicomedes, King of Bithynia, is said to have offered to release the Cnidians from the entire public debt of their city in exchange for their statue, but they refused his offer. What was the ultimate fate of this famous statue is not known. Some authorities have fancied that the celebrated figure known as the Venus de' Medici is, if not the Cnidian Aphrodite, at least an ancient copy of it; but this is very improbable. There is a bronze coin of the city of Cnidus, of which a good impression is in the cabinet of the Louvre, which has on one side a figure of Aphrodite, who has undraped herself for the bath, a portion of her drapery being held in her left hand, and resting on a vase; and this figure may be reasonably presumed to be a copy of that which the citizens so highly esteemed. Much more nearly accordant with this figure than the Venus de' Medici, is a statue of Venus in the gardens of the Vatican, which, though certainly not the Aphrodite of Praxiteles, is now held by most authorities to be an ancient copy of it. (Muller, 'Archäol. der Kunst,' § 127.) Though inferior as a work of art, and wanting in the refinement of the Medicean Venus, this statue has still something of a grander and loftier character. From the time of Praxiteles Aphrodite was represented more and more as simply a beautiful woman—gracefulness, tenderness, voluptuousness, *naïveté*, or a languishing sensuality, being the character imparted by expression, form, and pose according to the feeling of the artist or the desire of the patron. To this later period belong the earliest representations of the sea-born Aphrodite, or Venus Anadyomene. By Praxiteles and later Greek artists heteræ noted for their beauty were often represented in the character of Aphrodite; and there still exist several portrait statues of ladies of the Imperial families of Rome as Venuses, by Græco-Roman sculptors: some of them examples of almost the lowest stage of the decline of art.

In sculpture, but still more frequently on gems, Aphrodite is represented grouped with Eros; with the Charites; with Adonis; alone, or with the other goddesses before Paris. On vases, gems, and terra-cottas, she is seen persuading Helen to fulfil her promise to Paris; carried through the air on a swan; in a shell among nereids, &c. One picture of Aphrodite by Apelles has been mentioned; another which he left imperfect, was so much esteemed that no artist dared to complete it. The peculiar attribute of Aphrodite is the cestus (κεστὸς ἱμὰς, 'Il.' xiv. 214), or embroidered girdle, which had the power of inspiring love for the person who wore it. Her favourite animals were the swan, the sparrow, and the dove; her favourite plants, the rose and myrtle. The bird called inux, much used in amatory magic, was also sacred to her.

Representations of Aphrodite are to be found in most collections of ancient sculpture. Of several of the most esteemed in the public galleries of Europe, there are excellent casts in the Crystal Palace at Sydenham. In the sculpture galleries at the British Museum, will be found six or seven statues or torsi of Aphrodite of very considerable value. A small terminal statue closely veiled (in the third Græco-Roman saloon), "has been thought to represent the Venus Architis of the Phœnicians," but the correctness of this suggestion is very doubtful. An undraped statue of heroic size, in excellent preservation, represents Aphrodite preparing for the bath, with a vase and drapery by her side, and is a variety of the Cnidian type. Three of the others are undraped; one, of heroic size, the right hand and left arm alone modern, is half-draped, of the class mentioned above.

Of the existing statues of Aphrodite, that known as the Venus de' Medici is so much the most celebrated—being, indeed, one of the most famous, if it be not actually one of the finest, relics of ancient art—that a somewhat more particular account of it seems to be required. It stands in the apartment of the Imperial gallery at Florence, which is called the Tribune (Tribuna). It is said to have been found in the villa of Hadrian, near Tivoli, in eleven pieces, and was sometime afterwards carried to Florence in the pontificate of Innocent XI., about the year 1680. It is all ancient, with the exception of the right arm, the lower half of the left arm, some small piecings about the statue and its accessories, and the plinth. On the plinth is inscribed the name and country of the artist who made the statue: Cleomenes, the son of Apollodorus, of Athens—**ΚΛΕΟΜΕΝΗΣ ΑΠΟΛΛΟΔΩΡΟΥ ΑΘΗΝΑΙΟΣ ΕΠΩΕΣΕΝ**. This inscription was copied from that of the original plinth, which was broken. Its authenticity has been questioned, but on very insufficient grounds: Thiersch fixed the period of Cleomenes, for various reasons, to be about 200 years B.C., or certainly before the destruction of Corinth, B.C. 148. Flaxman also judges from its style that it was made after the time of Alexander the Great, and he seems to have considered it a copy of the celebrated Venus of Cnidus, by Praxiteles, an opinion expressed by Meyer, Winckelmann, and other critics, but, as we have said, apparently without sufficient grounds. Neither the time nor place of its discovery is positively known; but it stood, in the 16th century, in the Medici Gardens at Rome: the forum of Octavia at Rome is also said to have been the place of its discovery. It was taken by the French to Paris, but was restored to Florence in 1815.

It is a small figure, 4 feet 11¼ inches high without the plinth; is of Parian marble, and stands upon the left leg, which is strengthened by a dolphin with its head downwards, upon which two little cupids are sitting, called Eros and Anteros. The statue is of small but beautiful proportions, and all the parts are exquisitely rounded, but the face has little expression and not much beauty. The ears are pierced, and at one time bore ornaments; the hair was gilded, and on the upper part of the left arm there is the mark where probably a bracelet was fixed.

Mus.*; Larcher, *Mém. sur Vénus* (1775); Scharf, in Wordsworth's *Greece*; Thiersch, *Ueber die Epochen der Bildenden Kunst*; Visconti, *Oeuvres Diverses*, vol. iii.; Hirt, *Mythol. Bilderbuch*, vol. iv.; Müller, *Arch. der Kunst*, §§ 374—378, and references therein.)

APIIN ($C_{24}H_{14}O_{13}$), the name given by its discoverer, M. Braconnot, to a peculiar principle in parsley, obtained from it by solution in water. In cold water and alcohol it is nearly insoluble, but dissolves readily in either of them when heated, the solutions obtained gelatinising as they cool. The solution has a yellow colour. Apiin is soluble in the alkalies and in lime-water; the solutions are yellow, and when an acid is added, apiin is precipitated in a gelatinous state. When it is boiled with dilute acids, apiin undergoes a peculiar modification. If a small quantity of sulphuric acid be added to a boiling solution of apiin, it soon becomes turbid, and is converted into a thick yellowish fluid. On filtration after cooling, and saturation of the acid with chalk, a small quantity of sugar remains in solution; the portion precipitated becomes of a yellowish-white colour after washing and drying, and weighs but little less than the apiin submitted to experiment; it is neutral, inodorous, insipid, and insoluble in cold water, but it dissolves in boiling water or alcohol; the solutions do not gelatinise on cooling, but precipitate in white opaque flocculi.

Apiin dissolves in concentrated sulphuric and hydrochloric acids, and is precipitated from them by water in the state above described. M. Braconnot inclines to the opinion that this is pure apiin, and that that which gelatinises is a compound of apiin with one of the substances which the acids convert into sugar, an operation after which the apiin is exhibited in its proper character. Apiin produces a characteristic action with protosulphate of iron, producing with it a blood-red colour, which is so intense that about 16 grains of it dissolved in five gallons of water visibly colour it. The apiin which does not gelatinise produces the same effect: a solution of it in boiling water gives a blood-red precipitate with a solution of the salt of iron. With nitric acid apiin yields carbazotic acid and some traces of oxalic acid.

APIRINE, a dubious alkaloid, said by M. Bizio to be contained in the nut of the *Cocos lapidea*. Its composition is unknown.

APIS, a sacred bull, whose station and temple were at Memphis in Egypt. His Egyptian name was Heri, and he was regarded as the living son of the god Phtha. He must be distinguished from Mneuis, the sacred bull of Heliopolis. The real or true Apis was known from among all other bulls by certain marks, which are mentioned by Herodotus and Pliny (iii. 28; viii. 46). His birth is commonly described as miraculous; though produced from a cow, his conception was caused by the descent of lightning, or the influence of the moon's beams. When the bull Apis died, or had been put to death after living the prescribed number of years (according to some authorities), a successor was diligently sought for, and, when found, was installed in his temple of Memphis with all due solemnity. The cow was not eaten in Egypt, but the bull was used as food; yet no bull could be slaughtered till it had been first ascertained that it had none of the marks which characterised a sacred bull. When this was ascertained satisfactorily, the priests put a seal or mark on the animal, to signify that it might be slaughtered: no unstamped bull could be slaughtered, under pain of death. The object of the regulation was probably the raising of an income by a tax on slaughtered animals: there might possibly be other reasons also. (Herod. ii. 38.)

The worship of Apis existed at least as late as the reign of Septimus Severus. We hear of Greeks and Romans of rank paying their respects to the bull of Memphis, in which curiosity and superstition appear to have been blended. Alexander the Great, when he visited Memphis, sacrificed to all the gods, and Apis among the rest. The Persians, on the other hand, regarded the worship of the bull with disgust, and Cambyses insulted the Egyptians by stabbing their deity. Germanicus Cæsar, when he visited Egypt in the reign of Tiberius, went to see Apis at Memphis. It was a favourable sign when the animal would take food from the hand of his visitor, and the reverse was looked upon as presaging misfortune. The bull refused what the hand of Germanicus offered, and the Roman general died shortly after at Antioch. Strabo describes the Apis and his temple in the following terms, at the time of his visit to Egypt (xvii. p. 807): "Memphis contains a temple of Apis, who is the same as Osiris. The bull Apis is kept in an apartment (σηκὸς), and is regarded as a god: he is quite white on the forehead and some other parts of the body, but in every other part black. By these marks they always decide which bull is to be the successor of Apis when he dies. In front of the apartment is an inclosure, in which there is another apartment for the bull's mother. They allow the sacred bull to come into this court or inclosure at certain times, and chiefly for the purpose of being shown to strangers." The bull Apis, according to Herodotus (iii. 29), was embalmed when he died; but if he lived beyond a given number of years, he was slaughtered and buried secretly. If he died a natural death within the specified time, he was buried with much solemnity in the temple of Serapis, at Memphis. Lucas says (vol. i. p. 345, 'Voyage fait en 1714') that he observed bulls' heads in several niches of the catacombs of Abousir: he also found a bull embalmed, and in a great chest, on which the head of the animal was represented; the case, he says, was gilded and painted. (See also 'Abd-Allatif,' De Sacy, p. 201.)

The deity Apis was probably a symbol of the Nile (Jablonsky, 'Panthéon,' Apis), or of the earth and fertility, as the cow also was in the Egyptian, and still is in the Hindoo mythology. The god Sivas, in the Indian mythology, has his sacred bulls, which are characterised by certain marks, and a colossal bull of stone is often an ornament of his temples. The bull (but not the cow) is still an object of worship in India. Colossal human-headed bulls, it will be remembered, are very prominent in Assyrian sculpture.

In Egyptian art Apis is represented as a pied bull, wearing on his head the solar disc. There are several representations of him in the British Museum: see vases 628, &c., in the Egyptian Gallery; figures in Cases 8 and 9 in the First Egyptian Room, &c. The tendency of the Israelites to fall into the idolatrous worship of the bull or cow is seen from the history in Exodus, xxxii.; and at a later period, Jeroboam, who had spent some time in Egypt, set up two calves, one at Dan and the other at Bethel, and established temples and priests, probably in honour of Apis and Mneuis respectively. (1 Kings xii.; compare Hosea, chap. x.)

APLANATIC LENS from the Greek *a*, *without*, and πλάνη, *deviation* or *aberration*) is one which should be capable of so refracting all the rays which, diverging from or converging to one point in the axis, are incident upon it, that after being transmitted through it they may converge to or diverge from one other point in the same axis.

A single lens bounded by parallel surfaces cannot be rendered aplanatic. But for the sake of correcting another defect, that of *chromatic aberration*, the object-glasses of telescopes are made compound, consisting of a lens of crown and one of flint glass, and such a combination besides being *achromatic*, can be rendered at the same time aplanatic for parallel rays. [OPTICS.]

APOCALYPSE. The word apocalypse (ἀποκάλυψις) signifies literally *uncovering*, *unveiling*, and is used in the New Testament to express especially an extraordinary revelation of the will of God. In this sense the apostle Paul speaks of his "preaching Christ according to the *revelation* (κατὰ ἀποκάλυψιν μυστ.), of the mystery, which was kept secret since the world began, but now is made manifest, by the commandment of the everlasting God made known to all nations for the obedience of faith."—Rom. xvi. 25, 26. Compare also 1 Cor. xiv. 6, where we find that when the Christians assembled, every one had a psalm, a doctrine, a tongue, a revelation (apocalypse), or an interpretation. In these and similar passages the gift of teaching, of interpreting, and of announcing future events is distinguished from the revelation (*apocalypse*) of the council of God to the spirit of the receiver.

But the word apocalypsis is used in a still more confined sense, to express especially the prophetical revelation of the future development of the Messiah's kingdom. Works which describe future conflicts between the power of the Messiah and the opposing powers of Satan, unbelief and superstition, form the apocalyptical literature. The revelations in these works communicate visions in symbolical language. The *apocalyptical* is a branch of the *prophetical* literature. Every *apocalyptical* book is prophetical, but every prophetical book is not apocalyptical.

Apocalyptic writings develope that future kingdom of the Messiah which constitutes an essential part of the Biblical doctrine in the Old as well as in the New Testament. Apocalyptic, as well as profane, literature, has its epochs and periods of flourishing and of decay; and it is divided into canonical and apocryphal branches.

The first epoch is the Jewish. The book of Daniel is the prototype of all subsequent apocalypses. The fundamental idea of Jewish apocalyptics is the first advent of the Messiah in order to lay the foundation of his kingdom. In the Jewish apocalyptics, everything concerning the Messiah is future.

The second, or the Christian, epoch, of apocalyptic literature begins after the development of Christ's kingdom; consequently, the Christian apocalyptics are clearer than the Jewish. The Jewish apocalyptics still continued after the first advent, as long as the ideas about the Messiah retained great vigour among the Jews; but they degenerated into apocryphal imitations of earlier apocalypses. These apocryphal apocalypses of later Jews were often interpolated by Christians. The decay of the Jewish apocalyptics after the first advent was necessary; because Christianity is the only true continuation of Biblical Judaism. The stream of Jewish apocalyptics is lost in the sands of the Talmud. Some account of Jewish apocryphal apocalypses have been given under the articles ENOCH, EZRA, ISAIAH, in the BIOGRAPHICAL DIVISION of the ENGLISH CYCLOPÆDIA, and a further account will be given under PATRIARCHS, in the present Division.

In the history of the Apocalypse, we have to consider who was the author of the work who calls himself at the commencement of the first chapter: "Johannes a servant of the Lord." Some critics have asserted that this description which the author gives of himself is a proof that the Apocalypse was not written by the apostle St. John, but by another servant of the Lord, who would not assume any apostolic dignity; and, further, that in the usual title of the book (Ἀποκάλυψις Ἰωάννου τοῦ θεολόγου) he is not called St. John the apostle, but only John *the divine*, or the theologian. But most critics suppose that the present title to the Revelations can only refer to that apostle who wrote more explicitly about the divine *logos* (θεοῦ λόγος) than any other of the evangelists. Whoever compares the phraseology, imagery, and doctrine of the Apocalypse with that of the gospel and the epistles of St. John, will, indeed, find a great difference. The Greek style of the Apocalypse is strongly tinctured with Hebraisms, and its imagery is bold. The style of the gospel and the epistles approaches more nearly to the classic Greek, and is almost without imagery.

Polycarp, bishop of Smyrna, a successor of one of those pastors to whom the seven apocalytical letters in chap. ii. and iii. were addressed, was a disciple and friend of St. John the apostle: and Papias, bishop of Hierapolis near Laodicea, was, according to the statement of Irenæus ('Adv. Hær.' v. 33), "a hearer of John and a friend of Polycarp." Polycarp and Papias were highly esteemed authors. Polycarp's letter to the Philippians is still extant, but of the writings of Papias some fragments only have been preserved. In Polycarp's letter to the Philippians the Apocalypse is not mentioned; but his disciple Irenæus acknowledges its authenticity, and appeals to the testimony of those who had seen the face of St. John.

We have the testimony of the two Cappadocian bishops, Andreas and Arethas of Cæsarea, who lived in the last quarter of the 5th century, that Papias recognised the inspiration and authenticity of the Apocalypse. Andreas says, at the conclusion of his introduction to his commentary on the Apocalypse, "It is unnecessary to make many words about the inspiration of the Apocalypse, since those blessed men, I mean Gregory the theologian and Cyril, and besides these the more ancient also, Papias, Irenæus, Methodius, and Hippolitus, testify to its credibility." Arethas being later, repeats nearly the same statement in the preface to his own commentary. Papias died, according to the Alexandrine Chronicle, A.D. 163; therefore he must have been very young when he heard St. John, who died about A.D. 98.

Justinus Martyr, who flourished between A.D. 130-160 ,and was nearly contemporary with Polycarp and Papias, was born in Palestine, and acquainted with Alexandria, Rome, and Asia Minor. At Ephesus he held his famous dialogue with Trypho the Jew, which is still extant. Justinus Martyr quotes in this dialogue Jer. lxv. 17, &c.; Gen. ii. 17; Ps. lxxxix. 4, to support his doctrines about the millennium, and adds, that John the apostle, in the Apocalypse, likewise prophesied, that the believers in Christ should dwell in Jerusalem 1000 years before the general resurrection and final judgment should take place.

Melito, bishop of Sardes, to which town one of the apocalyptical letters is directed, belonged to the Biblical critics of the 2nd century, and wrote, according to Eusebius, "on the devil and the Apocalypse of John." Jerome says, in effect, the same.

Probably at the conclusion of the 2nd century, Theophilus, bishop of Antioch, wrote against the heresy of Hermogenes. This work is lost, but Eusebius, who read it, testifies that Theophilus took some proofs (μαρτυρίας) from the apocalypse. Theophilus seems also to use apocalyptical language in his work ('Ad Autolycum,' ii. 28); "the demon (devil) is also called dragon (δράκων)." Hence we infer that the Apocalypse was known in the second century, and influenced the language of the Christians.

Eusebius mentions likewise that Apollonius (who was, according to the book 'Prædestinatus,' which was written in the 5th century, bishop at Ephesus in the 2nd century) quoted the Apocalypse against the Montanists themselves, although these heretics derived their errors especially from this part of the New Testament.

But the most important testimony in favour of the Apocalypse is that of Irenæus, who died bishop of Lyons, A.D. 202. Irenæus, in his work against heretics, quotes long passages from the Apocalypse of John, whom he calls expressly the "disciple of Jesus" and "the recipient of the revelation." This presupposes that its canonical character was then generally recognised. Irenæus defends the apocalyptical number 666 against the spurious 616, by stating that all warranted old manuscripts contained 666, which number was also supported by the testimony of those who saw the face of John. Irenæus modestly confesses his own inability to explain this number, and says: "If the name of antichrist were to have been openly proclaimed in our days, it would have been declared by him who saw the revelation, for it was seen not a very long time ago, but almost in our own age, namely, at the conclusion of Domitian's reign." This testimony is important, because Irenæus was born in Asia Minor, where the Apocalypse was published; and he grew up in friendly intercourse with Polycarp of Smyrna. Irenæus knew the friendly circle of St. John, and the accounts which were in vogue among his disciples. Irenæus had a very extensive acquaintance with the most distinguished Christians in the east and west, and took a lively interest in the religious differences and theological debates of the second century; consequently, we have reason to say, that Irenæus was a qualified witness. There can be no doubt that he believed the Apocalypse was written by John. Irenæus mentions that the authenticity of St. John's gospel was attacked by some, but he mentions no opposition to the Apocalypse.

The letter by which the Christian congregations at Vienne and Lyon report to those in Asia and Phrygia the persecutions suffered under Marcus Aurelius, A.D. 177, proves likewise that the Apocalypse was then much read and generally recognised in Gaul and Asia. Irenæus was presbyter at Lyon when this letter (see Eusebii 'Hist. Eccles.' v. 1—3) was written, and, perhaps, it was drawn up by him or under his direction. The numerous Greeks who migrated from Asia Minor into Gaul probably took with them the Apocalypse.

The third century is the most interesting in the history of the Apocalypse. The disputes against the Montanists raised, among other theological questions, that concerning the authenticity of the Apocalypse. [MONTANISTS.] Tertullian, in his Montanistical writings, constantly appeals to the Apocalypse, and presupposes its genuineness. (Marc. 4, 5.)

It is very important that the spiritualising Origen not only mentions the Apocalypse as being written by John ('Comment. in Ev. Joannis,' ed. Lommatzsch, tom. i. lib. 6), but says very decidedly in his Commentary, that John, who reclined on the breast of Jesus, wrote the Apocalypse. Origen classified the books then used by Christians into genuine, spurious, and of uncertain authority, and numbers the Apocalypse among the genuine canonical books.

Origen was the greatest biblical critic of the 3rd century; and it is an important fact that, in investigating the canonical limits of the New Testament, he did not meet, either in the schools of Alexandria, or in his numerous theological peregrinations, with any sufficient reason for doubting the apostolical authority of the Apocalypse. In spite of opposition from a sect called the Alogi, who asserted that the Apocalypse was an unintelligible and irrational fabrication of Cerinthus, it maintained its authority to the middle of the 3rd century in churches far distant from each other, and it was used in theological researches and ecclesiastical transactions as a holy writing of the apostle St. John. But the Syrian national church, which was established either at the conclusion of the 2nd or the beginning of the 3rd century, omitted in the Peshito the second and third epistles of John, the second of Peter, the epistle of Jude, and the Apocalypse. These parts were added to the Syrian New Testament in or after the 6th century. But Theophilus of Antioch in the 2nd, and Ephraem Syrus in the 4th century, quote the Apocalypse, and ascribe it to John. Hence we perceive that the Apocalypse, although wanting in the Peshito, was recognised among the theologians of the Syrian church. (Compare 'Lengerke de Ephraemi Syri Arte Hermeneutica,' p. 5—8.)

During the 4th century the Apocalypse was used in the oriental church by Athanasius, Basilius Magnus, Gregorius Nyssenus, Didymus, Ephraem Syrus, and others. But Cyrillus of Jerusalem, who died A.D. 386, in his fourth Catechesis, advises his catechumens to read only those writings of both Testaments which were received by the church, and to neglect the apocryphal publications. Cyrillus gives a list of these canonical writings, in which the Apocalypse is omitted. But his fifteenth Catechesis seems to contain allusions to the apocalyptical phraseology.

The canon of the synod of Laodicea, which was held about A.D. 363, rejects the Apocalypse from the ecclesiastical canon; and so likewise the eighty-fifth of the apostolical canons, which belong, perhaps, to the 4th century.

Gregorius Nazianzenus says, in his verses on the genuine books of the inspired Scripture, after having mentioned all the other books of the New Testament except the Apocalypse, "Thou hast them all. If there is another besides these, it belongs not to the genuine." But the same Gregorius quotes, in his other writings, the Apocalypse as if he considered it genuine, and he is mentioned by Andreas and Arethas among those who recognised its inspiration and canonical character. Therefore, it is probable that the Apocalypse was reserved to the use of the clergy, who, remembering the Montanistic abuses, endeavoured to get the Apocalypse out of the hands of the laity without denying its genuineness. By this conjecture an apparent contradiction is solved.

The general ecclesiastical tradition as to the apostolical origin of the Apocalypse continued uninterrupted to the middle of the third century, except by the opposition of the Alogi. But Dionysius, a disciple of Origen and bishop of Alexandria, who died A.D. 265, though he admitted the Apocalypse to be above his comprehension and the work of an inspired man, gave various reasons for supposing it not to be written by the apostle John. These reasons were subsequently reproduced in substance by Erasmus, as we shall presently mention; and indeed, every later opposer has repeated the same arguments.

The synod of Toledo, A.D. 633, speaks of "many who do not receive the authority of the Apocalypse, and despise it so much, that they do not preach it in the church of God;" but with these despisers the synod makes short work, saying, "the authority of many councils, and the decrees of the Roman bishops, prescribe that it is of John the Evangelist, and appoint that it is to be received among the Divine books." "If, henceforth, any one does not receive it, or does not preach from it between Easter and Pentecost, at the time of mass, he shall have the sentence of excommunication."—(Harduin, 'Act. Con.' tom. iii. 584.)

The synod indicates the then prevailing opinion, which continued undisturbed during the middle ages. Isidorus of Seville, who died 636, described in his work, 'De Officiis Ecclesiasticis,' the New Testament canon exactly as the church considered it henceforth to be established and closed. According to Isidorus, the Apocalypse concludes, as being truly apostolical, the whole canon. But it is remarkable, that the 'Decretum Aquisgranense,' by Charlemagne, A.D. 789, cap. 20, decrees, that according to the synod of Laodicea, only canonical writings should be read in the church. The canon of Laodicea is added, in which the Apocalypse is omitted. 'Corpus Juris Germ.' ed. Walter, tom. ii. p. 1, p. 77, seq. But it appears from Augusti's 'Denkwürdigkeiten aus der Christlichen Archäologie,' b. vi. p. 113, &c., that the Apocalypse continued to be publicly read in the Western church.

During the middle ages, the anticatholic sects, as well as orthodox divines, appealed to the canonical authority of the Apocalypse, although they differed widely in its interpretation; but with the Reformation began another period in the history of the Apocalypse.

Erasmus ('In Annotationibus in Novum Testamentum,' 1516) reminded his contemporaries of the former doubts, and repeated them more fully in the edition of 1527. He states that from the title, 'Johannes Theologus,' the frequent repetition of John's name, the difference of style, and the manner in which the author speaks of his own visions less modestly than Paul (2 Cor. xii. 1, seq.) who relates them as if they happened to another, we might feel inclined to ascribe the Revelations not to John the Evangelist, if the general consent, and especially the authority of the church, had not already settled its genuineness. Nevertheless he relates, apparently with predilection, the opinions of Dionysius, and the uncertainty of Eusebius whether it belonged to the Homologoumena (the admitted), or the Antilegomena (the disputed).

What Erasmus had cautiously whispered into the ears of the learned Carlstadt and Luther proclaimed boldly to the people. Carlstadt, in his book, 'Welche Bücher Biblisch seint,' 1520, p. 4, divides the New Testament into three classes, the last of which contains the Epistle to the Hebrews, the two Epistles of Peter, the three Epistles of John, the Epistle of Jude, and the Apocalypse; and he adds, that, among all books of the third order, the Apocalypse is the least valuable, because, he says, it was not received in the days of Hieronymus by all Christians; secondly, the title is not Apocalypsis of John the Apostle, but of John the Theologian. Thirdly, its style and manner differ from those of John the Apostle. "But," says Carlstadt, "I will this and the other books of the third order not reject, but only point out the difference." In the preface to the Apocalypse, in the first edition of his German Testament, A.D. 1522, Luther writes: "In this book of the Revelation I leave every one to his own opinion, and I will bind none by my view and conclusion. I say only what I feel. In this book more than one thing is wanting, so that I consider it to be neither apostolical nor prophetical. First, the Apostles deal not in visions, but prophesy in clear and dry words, as do Peter, Paul, and Christ himself in the Gospel. It befits the apostolic office to speak clearly, without imagery, about Christ and his doing. But there is no prophet in the Old Testament, much less in the New, who so entirely deals in visions and imagery; so that I deem it only equal to the fourth book of Ezra, and indeed cannot perceive that it was dictated by the Holy Ghost.

"It appears too much that the author should recommend his own in preference to other holy books, which are much more important, and that he commands and threatens God would take from him whosoever would take anything from the Apocalypse; and again, that they should be blessed who keep what is written therein, although nobody knows what it is, much less can he keep it, and it is just as much as if we had it not. There are also many nobler books which we have to keep. Many of the fathers have in former days rejected this; and although St. Hieronymus, with high sounding words, asserts that it is beyond all praise, and contains as many secrets as words; he cannot prove it, and various passages of his praise are too mild (namely, towards this book). Finally, everybody may think of it what his own spirit permits him (what he pleases). My spirit cannot accommodate itself to this book, and it is sufficient cause for me not highly to esteem it, that Christ is neither taught nor known in it, which, before all things, an apostle ought to do, because he says (Acts i.), 'Ye shall be my witnesses.' Therefore I adhere to those books which give me Christ clearly and purely." This preface of Luther was repeated in all editions until A.D. 1534.

The opinions of the reformer influenced the Lutheran theology during the sixteenth century so much, that it became habitual to divide the New Testament into canonical and apocryphal books. To the canonical books only was ascribed an absolute authority in matters of faith; and the Apocrypha, to which the Apocalypse was referred, were considered as subsidiary sources of information. (Compare Oeder, 'Christlich freye Untersuchung,' pp. 51, 313; Hartwig's 'Apologie der Apokalypse,' th. iii. pp. 35, 48; Storr's 'Neue Apologie,' p. 7. et seq.; and especially Bleek's 'Einleitung in den Brief an die Hebräer,' p. 449, &c.)

In the disputation at Bern, A.D. 1528, one of the Roman Catholic interlocutors declared that the Apocalypse was written by St. John, and that wherever the Christian church caused the biblical books to be printed, the Apocalypse was among them; but Zwingli replied, it could not be proved historically that the Apocalypse was written by the Evangelist. Another Roman Catholic interlocutor complained that the Protestants would not admit the testimonies from the books of Tobit, Baruch, Maccabees, and of the Apocalypse: to whom Oecolampadius and Zwingli replied, that the Protestants did not absolutely reject the Apocrypha, but they could not admit their authority in the important matter of faith, and they had not been generally received by the old church. (See Zwingli's 'Werke von Schuler und Schulthess,' 2 b. i. Abth. pp. 87, 169, &c.) Thus it appears that Zwingli, Oecolampadius, and Bucer, who was present at the disputation of Bern, agreed with Luther and his followers in their estimate of the Apocalypse.

The reformers of Geneva, Calvin and Beza, seem to be more favourable to the Apocalypse. They quote it often without mentioning the Lutheran classification of canonical and apocryphal books of the New Testament. Calvin uses, in his 'Institutio Relig. Christianæ,' the Apocalypse as canonical and apostolical, but does not interpret it in his 'Commentarii,' and thus obtained the often-echoed praise of Scaliger; "Calvin was wise not to write on the Apocalypse." Beza defends, in his 'Prolegomena to the New Testament,' its authenticity against Erasmus, but adds, that if it were not of St. John, he would ascribe it to St. Mark, on account of the similarity of style. On the authority of these reformers the Apocalypse was sanctioned as genuine in the 'Confessio Helvetica Posterior,' the Thirty-nine Articles of the Church of England, the 'Confessio Gallica,' and 'Conf. Belgica,' and zealously expounded by Theodori Bibliandri ('Explicatio Apocalypseos,' p. 8, Basel, 1549,) and by Artopœus (Francfurt, 1549), and Heinrich Bullinger, who defends it against Erasmus and Luther ('Cent Sermons sur l'Apocalypse,' Genève, 1565). Hyperius (in his 'Methodus Theologiæ,' p. 48, Basel, 1574), did not conceal that its authenticity had been doubted by some, but he declares it to be canonical on the authority of the most ancient fathers. So the theory and practice of the so-called reformed (Calvinistic) church were in the sixteenth century, decidedly opposed to those of the Lutheran.

The Socinians leaned more towards the reformed than to the Lutheran view. Faustus Socinus ('De Auctoritate Scripturæ Sacræ,' opp. i. 268) declares the Apocalypse to be genuine.

Towards the middle of the eighteenth century, the doubts about the authenticity of the Apocalypse were revived first in England by a Deist, namely, the unknown translator of 'The New Testament, in Greek and English, containing the Original Text,' &c., dedicated to the Lord Chancellor, Peter King, London, 1729; and with more penetration by the anonymous author of the 'Discourse, Historical and Critical, on the Revelation ascribed to St. John.' It is now known that this Discourse was written by Firmin Abauzit, the famous librarian at Geneva, a friend of Bayle and Newton, at the request of W. Burnet. It was originally written in French, under the title 'Discours sur l'Apocalypse.' The original was printed, contrary to the wish of Abauzit (who died in 1767), in the edition of his 'Œuvres Diverses,' London, 1770. Abauzit's essay gave a new impulse to these critical investigations; and it induced Dr. Leonhard Twells to write his defence of the Apocalypse in the third part of his 'Critical Examination of the late Text and Version of the New Testament in Greek and English,' 1732; which contains the first essay of a solid defence of the Apocalypse by internal and external arguments. T. C. Wolf inserted an abridged translation of this work in his 'Curæ Phil. et Crit.' vol. v., p. 387. The excellent work of Twells, which silenced the adversaries of the Apocalypse in England, became known in Germany, where, after thirty years, the combat was renewed.

There was a time when the philologists of Germany generally did not recognise the æsthetical value of the Apocalypse, being influenced by the opinions of Oeder, Semler, and his followers. Herder and Eichhorn, equally learned, without any predilection for orthodoxy, but with more tact than Semler and his school, showed that the despisers of the Apocalypse had only manifested their own want of taste, when they denied the æsthetical value of the Apocalypse; and thus, without being orthodox, Eichhorn facilitated a decision favourable to orthodoxy. Herder observed, that every Christian poet who had a spark of real poesy, enjoyed the Apocalypse; that the best hymns of the middle ages, on Jesus, Mary, the church, and the kingdom of God, are crowned with apocalyptical flowers; that Dante, Petrarch, and Milton were imitators of the Apocalypse.

There is in the Apocalypse neither the plastic beauty of the antique, nor the picturesque beauty of our western modern poesy; the oriental poetry loves immensity. The apocalyptical imagination opens heaven and hell, and, rising high above human and terrestrial forms, breaks through the limits of humanity and temporal existence. It calls down the heavenly Jerusalem, dimly shadowed forth by the things temporal. The poetry of the Apocalypse is that of infinity, of destruction, and of endless power.

Bretschneider, Bleek, De Wette, Ewald, Scholt, Lücke, have written against the authenticity of the Apocalypse. Their works contain further developments of the old arguments of Dionysius.

Hänlein, Schmidt, Kleuker, Hug, Eichhorn, Feilmoser, Lange, Bertholdt, Guerike, Olshausen, are modern defenders of the authenticity of the Apocalypse; to whom we may add among the English, Lardner, and his epitomisers, Dean Woodhouse, the Rev. Hartwell Horne, and others.

The most recent German opposers fairly grant, that the external testimonies are decidedly in favour of the authenticity, but they assert that these testimonies are overcome by the internal philological character of the work.

The Apocalypse has been attacked and defended with greater zeal than any part of the New Testament, because its contents excite a very strong interest either in favour or against this conclusion of the whole Bible. The fundamental idea of the Apocalypse, which Luther and other opposers of the Revelations did not understand, is the following: As Plato, in his books Περὶ Πολιτείας, considers the state to be an exact transcript of individual man, so St. John, taking yet a higher step, tells us in the Apocalypse that similar events, which happen in the life of individuals, shall also take place in the infinity of the whole universe. Professor Stuart of Andover, in the United States, in his Commentary on the Apocalypse, has very ably controverted the arguments of the opposers of its authenticity, and has successfully proved its right to admission among the canonical books, though his theory of the right interpretation of the book is more doubtful.

As the redemption of Christ saves the whole man,—spirit, soul, and body,—so Jesus Christ saves also the universe from sin and consequent perdition. The Apocalypse teaches by a sublime imagery, what the other apostolical writings more obscurely indicate; namely, that there shall be a period in which the spirit of the Lord shall not only operate in secret by governing the hearts of believers, but a period in which it shall entirely conquer, prevailing against all opposition, and shall finally establish a kingdom of universal peace and justice here on earth.

The leading idea, then, of the Apocalypse consists in the complete victory of what is good, and of Paradise regained, or re-established on earth.

APO'CALYPTIC KNIGHTS (Cavalieri dell' Apocalisse) were a secret society, formed A.D. 1693, professedly for the defence of the Roman Catholic church against Antichrist. The founder of the Apocalyptic order was Agostino Gabrino, the son of a merchant at Brescia. When, on Palm Sunday, 1693, in the church of St. Peter at Rome, the antiphony of Ps. xxiv. was sung: 'Quis est iste rex gloriæ?' 'Who is that king of glory?' Agostino Gabrino stepped forward with a drawn sword among the ecclesiastics, crying out, 'Ego sum rex gloriæ,' 'I am king of glory.' In a similar manner he disturbed public worship in the church of St. Salvator, and was, therefore, confined in a madhouse. A woodcutter belonging to the Apocalyptic knights laid information before the Inquisition against his order; by this tribunal the order was suppressed in 1694, and the knights confined in prison. About eighty knights, most of whom were tradesmen and labourers, wore constantly a sword at their side, even during menial occupations, and a star upon their breast. This star had seven corners, and a tail, and was surrounded by a golden thread, which circle represented the terraqueous globe. The tail of the star represented the sword seen by St. John in the Apocalypse. This order has been accused of an intended rebellion against the papal government and the higher ranks. Agostino Gabrino, called monarch of the Holy Trinity, intended to introduce polygamy, and his knights were to marry pure virgins only. The history even of such a set of madmen is not without its uses: ignorance and fanaticism will, in all ages, produce the same fruits. (Tenzel, 'Monatliche Unterredungen' for the year 1694, pp. 672-677, and of 1697, p. 883, &c.; Ersch and Gruber's 'Ency.')

APOCRENIC ACID. [CRENIC ACID.]

APO'CRYPHA (ἀπόκρυφοι βίβλοι) are such books as contain secrets and are kept in secret, from ἀποκρύπτειν, to conceal; consequently the term referred to those writings of the Gnostics and other sects which contained the knowledge of those mysteries which were communicated to their partisans only. These books are now known under the name of *pseudepigraphi*, (that is, 'books with false titles,') as the books of Adam, Enoch, the three patriarchs, &c. These volumes formed a kind of heretical canon in opposition to the orthodox canon, and hence arose the signification of the name Apocrypha, which now means *not canonical*, or not belonging to those writings which form the canon of the Holy Scriptures.

The name Apocrypha is especially given to those additions which were introduced into the Septuagint translation of the Old Testament, from whence they were transferred into the Vulgate and many subsequent translations. They are undoubtedly of early date, and are supposed to have been rejected by the first council of Nice in A.D. 325, or rather that the other books then received the sanction of the church, but no list of the books decided upon as authentic is given in the canons then issued. The reformers separated the Apocrypha from the Old Testament, and Luther placed them between the Old and the New Covenants, under the title of Apocrypha, or books which are not to be esteemed equal to the Holy Scriptures, but are still profitable to the reader. In opposition to the reformers, the Apocrypha were declared to be canonical by the council of Trent. Hence all translations which follow the Vulgate have the Apocrypha interspersed with the other writings which are admitted by all Christians to be canonical. The Bibles published by Protestants on the continent place separately—the additions to Esdras; the book of Tobit; Judith; rest of Esther; Wisdom of Solomon; Ecclesiasticus; Baruch, with the epistle of Jeremiah: the song of the Three Children; Susanna; Bel and the Dragon; the Prayer of Manasseh; the books of the Maccabees. About the year 1821, a debate arose in the British and Foreign Bible Society about the propriety of printing the Apocrypha together with the Holy Scriptures. About 1826, it was decided that the Apocrypha should not be circulated by the British and Foreign Bible Society. Nevertheless the disputes of the two opposite parties were continued for several succeeding years, and many pamphlets were published by both parties, until the apocryphalists were finally defeated by the anti-apocryphalists. Besides the Apocrypha, which form a kind of appendix to the Old Testament and belong to the literature of the later Jews, there are a number of other apocryphal writings of the Old and New Testaments, which have been collected by Fabricius in the 'Codex Pseudepigraphus Veteris Testamenti,' and the 'Codex Apocryphus Novi Testamenti,' and more completely by Thilo in the 'Codex Apocryphus Novi Testamenti,' Lipsiæ, 1832. Most of the apocryphal additions to the New Testament were collected and published in an English translation by William Hone, in 1820.

APOGE'E, from ἀπὸ, *from*, and γῆ, *the earth*, an astronomical term applied to the apparent orbits of the sun and moon, signifying the points of those orbits which are at the greatest distance from the earth. It is opposed to PERIGEE, which means the point nearest to the earth. For general considerations connected with this term, see APHELION, substituting the earth in place of the sun.

The sun is in its apogee when the earth is in its aphelion, and the motion of the solar apogee is the same as that of the earth's aphelion. The motion of the lunar apogee is more complicated. At new or full moon, its longitude is increasing: at the quarters it is decreasing. But the increase, on the whole, is greater than the decrease: so that, on the average, the apogee increases its longitude daily by 6′ 41″, or describes a whole revolution in about nine years. In the 'Nautical Almanac' will be found the time when the moon is in her apogee and perigee for every month. For example, we find that in February, 1859, the moon is in apogee at twenty-seven days seventeen hours (meaning seventeen hours after noon on the 27th, or five in the morning on the 28th, civil reckoning). On referring to the moon's right ascension for that time, we find it to be nineteen hours, twenty-four minutes, fifty-two seconds.

APOGLUCIC ACID. [GLUCIC ACID.]

APOLLO, one of the principal gods of the Grecian heaven, also named Phœbus, and in Homer and Hesiod most commonly called Phœbus Apollo (Φοῖβος Ἀπόλλων). He was the presiding deity of archery, prophecy, and music, and in later times of the sun: but in the early poets above-mentioned, the sun (Helios) is a different personage, and of different extraction, the son of Hyperion and Theia. ('Theog.' xviii. 371: see also the adventures of Ulysses in the island of Thrinakia, where the oxen of the sun, not of Apollo, are always spoken of.) According to Herodotus (ii. 156), Apollo is the same with the Egyptian Horus, the son of Dionysus and Isis. The Grecian deity was the son of Zeus and Leto (Jupiter and Latona). His mother, when the time of travail drew nigh, wandered through the earth, unable to find a place which would give her rest; for every land, and river, and mountain, feared too much the wrath of Hera (Juno), the jealous queen of heaven, to receive her. At last Delos, which was then a floating island driven about the Ægean sea, and called Asteria, afforded her a place of repose, and Apollo was born. He immediately proclaimed his functions to the assembled goddesses who watched his birth. "The harp, the curved bow be mine, and I will proclaim to men the unerring counsel of Zeus." ('Hymn to Apollo,' v. 131.) Thenceforward Delos was fixed. Leto promised, in return for the shelter afforded, that her son should honour that humble island above all other places; and it was always held especially sacred to him, and the principal seat of his worship. This story is beautifully related in the Homeric hymn above quoted, and in the hymn to Delos by Callimachus. Apollo is a leading personage in mythological fiction, and a favourite with the poets, who have engaged him in a great variety of adventures. He was the president and protector of the muses. He is usually represented in the prime of youth and manly beauty, with long hair, his brows bound with the sacred bay-tree (*Daphne*), bearing either the lyre, or his peculiar weapon, the bow. In later times he usurped the presidency of the healing art from its earlier deity, Paieon; hence Æsculapius was said to be the son of Apollo. The hawk, the raven, the swan, the grasshopper (*cicada*), were his favourite animals. His principal temples were at Delos, Delphi,—at both which places his oracles were in the highest repute—Tenedos, Patara, Claros, &c.; and from these he derives a great variety of distinctive epithets. He has many others peculiar to himself, which principally refer to his skill in archery, or may be interpreted to contain some allusion to the sun; as far-shooting, silver-bowed, golden-haired, golden-sworded, light-producer, &c. Müller, in the second book of his 'Dorians,' and in his 'Archäologie der Kunst,' § 359, has endeavoured with great ingenuity and learning to show that the fundamental idea of Apollo was that he was, in his essence, a god of health and order, the protector of the good, the averter and the destroyer of evil, and that of these, the various powers and attributes ascribed to him are mere ramifications. "He was conceived," as Müller remarks, "as purifying by propitiatory sacrifices, tranquillising the mind by music, and directing by prophecies to a higher order of things." On the whole, the idea conveyed by the worship of Apollo was the most elevating of any in the Grecian theology.

The word Phœbus is apparently connected with a Greek root, signifying *light*; but the origin and meaning of the word Apollo are entirely unknown. In later writers, and by the Latins, who do not appear to have had an ancient sun-god of their own, Apollo and the sun are confounded. It is observable, however, that Ovid, in the stories of Phaeton, and Clytie, which have especial reference to him in his character of the sun, always uses the word Sol, not Phœbus or Apollo, except once (ii. v. 399) at the conclusion of the former (Met. ii. 1. iv. 190). In Homer and Hesiod, as we have said, the two are clearly distinct. It is maintained, however, by some mythologists, and among them by Buttmann, that originally Apollo and Artemis were the sun and moon, and that the later writers who assigned to those deities the presidency over the two great luminaries, only revived the original belief which had fallen into disuse. (Buttmann, 'Mythologus,' v. i. ap.; Keightley.)

In the most flourishing periods of Greek art, Apollo was regarded as the consummation of manly, as Aphrodite was of feminine beauty. In the earliest times, at Delphi and Athens, Apollo Agyieus was worshipped under the form of a conical stone. The early pillar statues were decorated with a lyre or with arms, according as they were dedicated to the tranquillising or the avenging deity. When Apollo came to be represented under a human form it was, before the time of Phidias, either as a youth of majestic beauty, or of a riper age and with a grave, earnest, or severe countenance. At this time he was represented both with and without drapery. Pliny mentions a bronze statue of Apollo outside the Parthenon, as one of the finest works of Phidias; and it may be taken for granted that the Apollo of Phidias was the perfection of physical and intellectual beauty and dignity. By Praxiteles, Scopas, and their contemporaries, greater slenderness and elegance of form was given to the god. The face was made more oval, the masculine characteristics were scarcely developed: altogether something of refinement, softness, and delicacy was substituted for the simple grandeur of the earlier form.

The statues of Apollo may be broadly divided, according to the principle of Müller, into those of the contending, or the appeased and reposing god ('Archäol.' § 361). In the one class he carries the bow, or is otherwise distinguished as an avenging or a protecting deity; in the other the lyre is a common characteristic. Sometimes he is represented in the Pythian costume. On vases, gems, coins, and sarcophagi, Apollo is very frequently figured grouped with other deities: with Marsyas; with Hyacinthus; with Daphne; on the swan; destroying the family of Niobe, and in various other ways; for throughout the cycle of Greek art, Apollo was a prime favourite with artists. As of Aphrodite, every European museum contains numerous ancient representations of Apollo. In the British Museum there is an undraped marble statue, of heroic size and of early date; a colossal foot, 2 feet 11 inches long; a bronze statue about 2 feet high; and several representations on rilievi, vases, coins, &c.

The most celebrated of the existing statues of Apollo, is that known as the *Apollo Belvidere*, which was found at Capo d'Anzo, in the ruins of ancient Antium, about twelve leagues from Rome, in 1503. It was purchased by Pope Julius II., before his elevation to the pontificate; and was placed by him in the Belvidere of the Vatican, whence it derives its present name. It has been said to be the work of Agasias the Ephesian, but no certain indications of the sculptor are to be traced. It is now believed to have been made under the emperors, and as some think by the order of Nero himself; from the folds of the cloak, and other indications, it is probably a copy of a bronze statue. Be that as it may, it is one of the finest specimens of sculpture extant. It is a standing figure, more than seven feet high, and represents the god naked, except the cloak which is fastened round his neck, and hangs over the extended left arm. The left hand and the right forearm were lost, and were restored by Giovanni Angelo da Montorsoli, a pupil of Michael Angelo: so that the original action of the figure can only be conjectured. It is supposed, however, to represent Apollo as the destroying god, "the lord of the unerring bow," but as to the precise intention of the sculptor authorities differ; the received opinion was that Apollo was represented at the moment of having discharged an arrow at the serpent Python, watching the effect of his weapon: and accordingly, in the restoration, part of a bow was placed in the left hand. But Feuerbach ('Der Vaticanische Apollo,' Nürnberg, 1833) believes that it was intended to represent Apollo chasing away the Furies. Again, it has been suggested (by Hirt and Wagner), and with great probability, that it represented the god as the destroyer of the children of Niobe: and various other interpretations have been proposed. A serpent, the emblem of the healing art, is fixed on the stump of a tree, which gives stability to the figure. Byron's fine description of it ('Childe Harold,' iv. 161) is well known.

APOLLO'NICON, the name given to a chamber organ of vast power, supplied with both keys and barrels, built by Messrs. Flight and Robson, of St. Martin's-lane, London, and first exhibited by them at their manufactory, in 1817. The Apollonicon was either self-acting by means of complicated machinery, or could be played on in the usual manner, by means of keys. The music, when the organ was worked by machinery, was *pinned* on three cylinders or barrels, of about two feet eight inches long, each acting on a distinct division of the instrument; and these, in their revolution, not only admitted air to the pipes, but regulated and worked the stops, forming, by an instantaneous action, all the necessary combinations. The key-boards were five in number; the central and largest comprising five octaves, and the smaller ones—two on each side the larger—two octaves each. To the central key-board were attached a swell, and some compound pedals, enabling the performer to produce all the changes and variety of effect that the music might require. The instrument had also a key-board comprising two octaves of other pedals, operating on the largest pipes. These six key-boards were detached from the body of the organ, so that the performers sat with their backs to the instrument, and, consequently, with their faces to the audience. There were

1900 pipes, the largest twenty-four feet in length, and one foot eleven inches in aperture, sounding the G, two octaves below the first line of the base: the highest pipe gave the A in altissimo, two octaves above the second space in the treble. The number of stops was forty-five, and these in their combinations afforded good imitations of the various wind instruments used in an orchestra. Two drums were also inclosed in the case, and struck by a curious contrivance in the machinery. A tolerably correct estimate of the capabilities of this instrument may be made, when it is stated that it performed Mozart's overtures to the 'Zauberflöte,' 'Figaro,' and 'Idomeneo;' Beethoven's to 'Prometheus;' Weber's to 'Der Freischütz' and 'Oberon;' Cherubini's to 'Anacreon,' &c., without omitting a single note of the score, and with all the fortes and pianos, the crescendos and diminuendos, as directed by the composers.

Considered as a self-playing instrument, the Apollonicon was provided with two revolving cylinders, studded like that of a barrel organ.

The Apollonicon was five years in building, and cost 10,000*l.* During many years it attracted the notice of professional and amateur musicians, both by its automatic and its keyed action. At length, however, some of the mechanism became disordered; and as the commercial return for the vast expense incurred had scarcely been adequate, the instrument was withdrawn from public gaze, and perhaps no longer exists. Some of the details in this article will be rendered more intelligible by referring to ORGAN.

APOLOGE'TICS (*theologia apologetica*, apologetik) is the designation given in Germany to that branch of divinity which is most intimately connected with logic, metaphysics, and general history, and has for its object a systematic arrangement of those internal and external evidences by which Christians are enabled scientifically to justify the peculiarities of their faith. The name is derived from a Greek adjective *apologéticos* (ἀπολογητικός).

Since Christianity was opposed from the beginning by men who denied its high origin and its intellectual superiority, circumstances demanded on the part of Christians a compliance with the express injunction of the apostle Peter, "Be ready always to give an answer (πρὸς ἀπολογίαν, for an *apology*) to every man that asketh you a *reason* of that hope which is in you." (1 Pet. iii. 15.) Separate apologies have the same relation to apologetics that separate mathematical treatises have to the science of mathematics.

The science of apologetics was not the offspring of literary vanity; it was unknown till the attacks of the adversaries of Christianity assumed a learned and scientific character. In the first centuries of our æra, whilst most opposers asserted that the Christian religion was the cause of famine and earthquakes; and that Christian worship consisted in eating children, drinking human blood, committing incest, and adoring the head of an ass, or some such abominations, separate apologies were sufficient for the refutation of these absurd charges. The name is of still later origin than the science of apologetics. The word *apologetik* was universally adopted after Gottlieb J. Planck had used it. (See his 'Einleitung in die Theologischen Wissenschaften,' 1794-8, vol. i. pp. 231-362.) As the fundamental idea of mathematics is that of quantity; of jurisprudence, that of right; of æsthetics, that of the beautiful; so the fundamental idea of apologetics is that of supernatural revelation. The apologetics contain a further development of one part of dogmatics or doctrine, which is called bibliology. Apologetics teach how to defend the fundamental ideas of Christianity against unbelievers; polemics teach how to attack those who, admitting the Christian revelation to be true, err in particulars.

The science of apologetics treats of the

I. Possibility of revelation.

1. Logical possibility. Logical refutation of those who, like John Toland, Edelmann, and Rousseau, considered the idea of revelation to be self-contradictory.

2. Theological possibility. Metaphysical refutation of those who considered the idea of supernatural revelation to be repugnant to the attributes of God, impartial justice, general love, and immutability.

3. Anthropological possibility. Refutation of those who, like Immanuel Kant, deny the ability of man to perceive the supernatural.

II. Necessity of revelation, to be demonstrated by historical and ethnographical induction, especially by the history of philosophy.

III. Reality of revelation, demonstrated by a development of the internal evidence of the peculiar Christian doctrines, and confirmed by the historical credibility of the Gospel history.

Apologetics, though based upon the Gospel, constantly require a new adaptation to the times for which they are written. There are many good apologies, but apologetics are yet in their infancy. Among the societies, foundations, donations, &c., which have an apologetic character, may be mentioned the Bampton Lectures at Oxford, Hulse's foundation of the Christian Advocate at Cambridge, the London Society for promoting Christian Knowledge, with all similar societies.

APOLOGIES OF THE FATHERS are writings in defence of Christianity, composed from the beginning of the second to the sixth century. The opposers of Christianity generally attacked the moral character of the Christians rather than their doctrines. The fathers of the church, with the view of refuting the doctrines of heathenism and the false accusations against the followers of Jesus, composed *Apologies*, which were partly addressed to all well-informed heathens, partly written on particular occasions, and addressed to emperors in order to convince them of the injustice and folly of persecutions.

The apologies of Quadratus and Aristides are lost. Justinus Martyr describes, in two apologies, how he sought for truth in various systems of philosophy until he found it in the Gospel. In his Dialogue with the Jew Tryphon, Justinus Martyr appeals to the prophecies of the Old Testament. The apologies of Justinus contain many materials for the history of philosophy. Athenagoras defended the Christians against the charge of atheism, incest, infanticide, and other abominations with which they were charged. Tatianus, Theophilus of Antioch, and Hermas, proved the absurdity of paganism and the contradictions of philosophers, in order to show the necessity of revelation.

After these Greek apologists of the second century followed, among the Latins, Tertullian, who, in his 'Apologeticus,' eloquently shows how the faith and holiness of Christians were especially manifested under persecutions; and Minucius Felix, who, in his eloquent dialogue, 'Octavius,' introduces the representatives of various parties, whose arguments are overcome by the truth of the Gospel. Cyprian wrote 'De Idolorum Vanitate,' or, On the Absurdity of Idolatry. These apologists of the second century did not defend the systems of certain schools, but only the truth of Christianity.

In the fifth century the doctrines of the Gospel were systematised by Origen among the Greeks and Arnobius among the Latins, in order to defend them successfully against the attacks of Celsus, Porphyrius, Hierocles, and Julian, which were directed not only against the morals of the Christians, but also against their history and their doctrines. These writers compared the miracles of Jesus with those of Pythagoras and Apollonius of Tyana, and questioned the credibility of the Evangelists. They recognised the leading facts of the Gospels, but endeavoured to prove contradictions in minor points. The objections are answered in the eight books of Origen against Celsus, who wrote his attack on Christianity about one hundred years before it was replied to by Origen. But the greatest apologist among the fathers is Eusebius, whose historical and chronological works have an apologetical tendency, and whose evangelical preparation (προπαρασκευὴ εὐαγγελικὴ, or Εὐαγγελικῆς ἀποδείξεως προπαρασκευὴ) contains, in fifteen books, the introduction to his Evangelical Demonstration (εὐαγγελικὴ ἀπόδειξις), in twenty books. The first ten books of this work are still extant, in which he demonstrates the harmony of the Old with the New Testament, the moral dignity of Jesus, the sublimity of his plan, the rectitude of his disciples, and the absurdity of those who ascribed another plan to the disciples than that which they professedly followed. Eusebius examines, in a little publication against Hierocles, the life of Apollonius of Tyana by Philostratus, and shows the contradictions of the biographer, the knavery of this notorious individual, and how his performances differed from the miracles of Christ. The works of Athanasius and Chrysostomus contain apologetical materials. Cyrillus of Alexandria wrote ten books in reply to the Emperor Julian. Theodoret wrote twelve sermons under the title, 'Ἑλληνικῶν θεραπευτικὴ παθημάτων ἢ εὐαγγελικῆς ἀληθείας ἐξ Ἑλληνικῆς φιλοσοφίας ἐπίγνωσις, in which he gathers the arguments for Christian truth from the writings of the heathens, and compares the Greek philosophers with Moses, the prophets, and the apostles. The most important apologetical works among the Latins are the seven books of Arnobius ('Adversus Gentes') against the heathen; the seven books of Lactantius, 'Institutionum Divinarum;' the twenty-two books of St. Augustin, 'De Civitate Dei;' the catalogue of St. Jerome, by which he refutes the objection that no distinguished individuals embraced the Gospel ('Catalogus Virorum Illustrium'); and, finally, 'Orosii libri septem Historiarum adversus Paganos,' in which he refutes the assertion that plague, famine, earthquakes, and other horrible events were consequences of the Gospel. The science of apologetics has made progress in the same ratio in which the attacks upon Christianity became more systematic.

The following translations and editions will be interesting to English readers. Justin the philosopher, commonly called Justin Martyr, died about A.D. 165. His 'Apologia prima pro Christianis,' published by Dr. Grabe, Oxon., 1700; 'Apologia Secunda,' by Hutchinson, Oxon., 1703; 'Justin Martyr's Full Account of the Christian Worship, Baptism, and the Lord's Supper, with Notes of Dr. Grabe and Mr. Whiston;' 'Dialogus cum Tryphone Judæo,' London, 1722, 8vo.; 'The Apologies of Justin M., Tertullian, and M. Felix, with the Commentary of Vincentius Lirinensis,' by Reeves, 1709 and 1716,—an unfaithful translation. 'The Dialogue with the Jew,' by Brown, London, 1755, is an excellent translation, and very scarce in the book-market. Minutius Felix, of the third century, author of 'A Dialogue between Cæcilius a Heathen and Octavius a Christian,' is well translated by Sir David Dalrymple.

APOLOGUE, synonymous with fable (ἀπόλογος, *fabula*, fable), "a novel story contrived to teach some moral truth." (Johnson.) "It would be a high relief . . to hear an *Apologue*, or fable, well told, and with such humour as to need no sententious moral at the end to make the application." (Shaftesbury, 'Characteristics,' vol. iii., 'Miscell.,' iv. c. 1.) It is essential to an apologue that the circumstances told in it should be fictitious. Some have gone so far as to say that they must involve an impossibility, as in Æsop's fables, where we find beasts and inanimate things made to think and speak.

APO'LOGY (ἀπολογία), a Greek word, originally signifying a defence made in a court of justice by or for a person accused. (See the titles of several of the extant Greek orations.) The word ἀπολογεῖσθαι, to 'apologise,' to 'make a defence,' was the corresponding verb. There is extant a small piece attributed to Xenophon, entitled the 'Apology of Socrates;' and another, with the same title, by Plato. The word apology was adopted by the Christian fathers. [APOLOGIES.] At the present day it is only used in ordinary language in one sense—that of "asking pardon or excuse for some offence." But even in modern times the word has occasionally been used in the early Christian sense, as by Bishop Watson, in his treatise entitled an 'Apology for the Bible,' and by Barclay, in his 'Apology for the Quakers.'

APOPHTHEGM (ἀπόφθεγμα), a Greek word signifying 'a thing spoken out,' and, in its more technical sense, a pithy saying calculated to arrest the attention. "Certainly apophthegms are of excellent use. Cicero prettily called them *salinas*, salt-pits, that you may extract salt out of, and sprinkle it where you will. They serve to be interlaced in continued speech. They serve if you take out the kernel of them, and make them your own." (Bacon.)

We may take the following as examples of apophthegms:—"Bigotry murders religion, to frighten fools with her ghost."—'Lacon.' "We ask advice, but we mean approbation."—Ibid. Plutarch made a collection entitled 'The Apophthegms of Kings and Generals,' and dedicated it to the Emperor Trajan. Many of these apophthegms would be classed in modern times among anecdotes. The following is an example; it is one of the apophthegmata placed under the head of Alexander:—"An Indian was taken prisoner who had a very high reputation for archery, and was said to be able to shoot an arrow through a ring. Alexander bade him exhibit a specimen of his skill, and on his refusal, the king in a passion ordered him to be executed. On his way to his death, the man remarked to those who were taking him, that he had not practised for several days, and was afraid of missing his mark. Alexander hearing of this, admired the man, and, setting him loose, made him great presents, because he preferred death to the loss of his reputation." (Wyttenbach's edit., vol. i. p. 718.)

The Lacedæmonians were noted for affecting the apophthegmatic mode of speech; and Plutarch has collected their sentences also under the title of 'Laconica.'

APO'PHYGE, a term applied by architects generally to a concave surface lying between or connecting two flat surfaces not in the same plane, and particularly to a slight concavity which is almost invariably found to terminate the shaft of an Ionic or Corinthian column both above and below,—immediately above the uppermost fillet of the congeries of mouldings called the base, and under the moulding or mouldings of the hypotrachelium or necking. In the latter case, the apophyge is distinguished in the two positions as the lower and the upper. The more familiar English term for the same thing is the *escape*, or *scape*; and in French, the apophyge is termed the *congé*. Apophyge is from a compound Greek word signifying a *flying off*. [COLUMN.]

APOPHYLLIC ACID ($C_{16}H_{7}NO_{8}$, HO) is obtained from narcotine. It crystallises with or without water; in the latter case the crystals have the form of rhombic octohedrons, which are colourless. The cleavage faces have a pearly lustre resembling apophyllite, and hence the name bestowed on this acid. The crystals lose water, when heated, even under water, and become white without altering their form; they contain 9 per cent. of water, and are but little soluble in water. A saturated boiling solution yields long prismatic crystals on cooling, which do not effloresce; the acid which crystallises from a solution that has not been boiled has the cubo-octohedral form, and contains water.

This acid has a slightly acrid and astringent taste; it reddens litmus-paper, and it is insoluble in alcohol and in ether. The salts which it forms with bases are soluble: the ammoniacal salt crystallises in tables, and is very soluble; the salt of silver, formed by double decomposition, is after a certain time deposited in stellated crystals, which gradually increase in size; they explode at a moderate heat with the same violence as oxalate of silver; the residue is as black as charcoal, and after combustion leaves metallic silver.

APOPLEXY, from ἀποπληξία, a sudden blow, a deprivation of power and motion, &c. *Morbus attonitus, sideratio, percussio*, &c., are synonymous terms. In the animal body two sets of functions perfectly distinct from each other are combined, the *organic* and the *animal*; the organic include the various functions by which the structure of the body is built up and its integrity maintained, and the animal include the functions of sensation and voluntary motion. [LIFE.] The disease termed apoplexy is an affection of the animal functions, the organic remaining comparatively unimpaired. It is the loss of sensation and voluntary motion, while respiration, circulation, secretion, and the other functions of organic life continue to be performed, though not indeed without more or less disorder.

Of all the diseases to which the human body is subject, there is none which is commonly conceived to attack so suddenly, and to kill so rapidly. What is usually called the attack is indeed sudden; but the disease itself, so far from being sudden, is generally even slow in its progress, giving distinct and repeated indications of its presence and of its course. The signs by which the apoplectic constitution is denoted, the *premonitory signs* of the disease as they are termed, it is of the utmost importance to observe, because judicious measures adopted at this stage will almost always avert an attack, or render an attack mild which would otherwise have been mortal. There are few other diseases over which both the physician and the patient have so much control: the patient by the general management of himself, in removing the constitutional predisposition to it; and the physician by active remedies when the attack is instant, in effecting what the general management may have proved inadequate to accomplish. Prevention is often practicable; but when the attack has once come on, life is in imminent peril: the most judicious and powerful remedies, though resorted to instantly, and employed with the greatest skill, are commonly unable to avert death; and even when they do succeed, the functions of the brain and the general health have usually sustained so severe a shock, that life is no longer worth possessing.

In general, the premonitory symptoms are steady in their nature, uniform in their course, and so obvious that all may perceive and understand them. Considered individually, they may appear numerous and diversified; but they are really so much alike, that they all obviously belong to one class.

Among the premonitory symptoms, the most remarkable are the following, which are here enumerated in the order of their importance and frequency.

1. Drowsiness. This feeling may exist in every degree, from unusual dulness of mind to an uncontrollable propensity to sleep.

2. The next premonitory symptom is giddiness. Giddiness is more alarming than drowsiness, and would never fail to produce a conviction of danger, but that giddiness often arises from other causes; for example, from a disordered state of the stomach.

3. Connected with these two important symptoms are a number of subordinate sensations, such as frequent yawning, dulness of hearing, imperfect or disordered vision, noise in the ears, motes or sparks before the eyes, repeated sneezing, occasional hiccup, and the like.

4. Pain in the head. The intensity of the pain may vary from the slightest uneasiness to the most intolerable headache.

5. Last in the train comes a symptom which is more important than any of the preceding, because it demonstrates their true nature, and shows that the actual attack is instant; namely, paralysis, whatever its form or degree, whether it assume the shape of inability to articulate distinctly, or to write steadily, or to walk firmly, or in reading to fix the eye on the right line, or in talking or laughing to keep the mouth in the natural position, or in deglutition to swallow without unusual difficulty, or without exciting cough. If with this loss of muscular power there be at the same time a sense of pricking over the skin, or a numbness in the limbs or fingers, or difficulty in voiding the urine, or distortion of the face or mouth, dropping of the eyelid, stammering, unsteadiness in the gait, and so on, the attack may be considered as having actually commenced.

Of these premonitory symptoms one alone may be present, or two may be combined, or several may co-exist or may follow each other in rapid succession. The period of their duration, before the attack supervenes, is different in every individual case. Sometimes there elapse only a few hours; more frequently several days; occasionally many weeks. When they are present, no man is safe from a fatal attack for a single instant.

With regard to the attack itself, the phenomena are different according to its intensity. There are, indeed, various modes or forms of the disease which are mainly matters of degree: nevertheless, these diversities are not only very striking in their own nature, but in a practical point of view are highly important, because the remedies appropriate to the one are not suited to the other, at least without such modifications as, in point of fact, to render them different remedies.

For all practical purposes it will be sufficient to comprehend the various forms of the disease under four heads, namely, first, that in which the attack is sudden and violent; secondly, that in which the attack is comparatively slight at the commencement, but progressively increases in severity; thirdly, that in which the attack commences with apoplexy and terminates in paralysis; and, fourthly, that in which the attack commences with paralysis and terminates in apoplexy.

1. The sudden and violent form constitutes the *apoplexia fulminans* of the older authors; the *apoplexia fortissima* of more modern writers; and the *apoplexie foudroyante* of the French. In this form of the disease the patient is struck senseless and motionless instantaneously: he falls down and lies utterly deprived of all the functions of the animal life. The organic functions in the mean time go on, but in an unnatural and disordered manner. The respiration is slow, deep, and accompanied with that peculiar noise which is called stertor; the pulse is fuller, stronger, and slower than natural; the urine and fæces are passed without consciousness; the skin is covered with a cold and clammy perspiration; foam flows from the mouth; the face is flushed, tumid, and sometimes even livid. Death may take place in a few minutes, or a few seconds, or not until the end of the first, or even the second, day; but life is seldom protracted beyond the second day. Now and then the prompt and vigorous employment of the appropriate remedies saves life even in this form of the disease; but if they fail to restore consciousness in a few hours, they commonly fail altogether, and death almost always happens when the paroxysm continues undiminished during twenty-four hours.

On examining the state of the brain after death from this variety of the disease, the blood-vessels of every part of the cerebral substance and of the delicate membranes that invest it, are found gorged with blood; there is also sometimes an effusion upon its surface, beneath its membranes, and within its cavities, of the thinner portion of the blood called serum, while, in many cases, pure blood itself is poured out on various parts of the brain from some ruptured vessel. Occasionally no morbid appearance can be detected sufficient to account for the attack, or for death, the consequence of it.

2. In the second form of the disease, in which the attack is less violent in the commencement, but progressively increases in severity, the loss of sensation and voluntary motion is neither sudden nor complete, or, if it be so, the abolition of these functions is only of momentary duration. Instead of stupor and coma, the patient is seized with a sudden and violent attack of headache, attended often with sickness and vomiting. The pain of the head is sometimes so severe that the patient sinks down under it, pale, faint, and exhausted, occasionally with a slight convulsion; but from this state of depression he recovers rapidly, still however remaining weak, faint, and chilly, with a quick and feeble pulse, a sunk countenance, and occasional vomiting. This state having continued from one hour to three, or more, the heat increases, the pulse acquires strength, the face becomes flushed, the sunk expression of the countenance disappears, and torpor or stupor rapidly supervenes, the patient appearing dull and heavy, answering questions slowly and with difficulty, and sinking at last into a state of profound coma. From the first invasion of the attack to the coming on of perfect coma, the period may vary from one hour to three days and more. This form of the disease is at least equally dangerous with the preceding, and, in fact, generally proves fatal.

On examining the state of the brain after death from this variety, there are found extensive effusions of blood; softening of the substance of the brain; sometimes ossification (conversion into bone) of portions of its membranes; but far more constantly ossification of the coats of its blood-vessels, which organic change in the structure of the blood-vessels diminishes their strength, renders them incapable of resisting the current of the blood and of carrying on the circulation, and thus predisposes them to rupture.

3. The third form of the disease commences with a distinct apoplectic paroxysm, which terminates in paralysis. When the apoplectic symptoms disappear, some part of the body is found to be paralysed; it may be the muscles of the face, giving rise to various kinds of distortion; or the muscles of the limbs, occasioning inability to move the affected member; or the muscles of one side of the body, producing what is called *hemiplegia*; or the muscles of one half of the body, *paraplegia*. In the great majority of cases the speech is more or less affected, the power of articulation being either wholly lost or greatly impaired. Often the sensibility seems unimpaired, the patient endeavouring to express himself by words or signs; but, at other times, the mind itself is indistinct, confused, rambling, and incoherent. Occasionally in this form of the disease, the apoplectic state disappears rapidly, while the paralysis remains for years. Sometimes the paralysis slowly diminishes until suddenly another apoplectic attack supervenes, leaving the paralysis greater than before; at other times the paralysis continues undiminished for days, months, and years, until a second, or a third, or a fourth apoplectic paroxysm at length destroys the patient. In the few cases in which there is a perfect recovery from the paralysis, the mind is always slow in recovering its energy, and often never regains it.

On examining the state of the brain after death from this variety, there is commonly found an extravasation of blood into a defined cavity formed in the substance of the brain, constituting what is termed an apoplectic cell; but although this be the most ordinary form in which the blood is effused in this variety of the disease, yet there may also be a general extravasation of it, as in the other varieties, or mere effusion of serum; or softening of the cerebral substance, or ossification of the membranes, or of the blood-vessels, or several of these morbid conditions may be combined.

4. In the fourth and last form of the disease, in which the attack commences with paralysis and terminates in a complete apoplectic paroxysm, the premonitory symptoms are in general very distinctly marked. Drowsiness, giddiness, disordered vision, impaired memory, and pain of the head especially, commonly precede the attack. While the brain is thus affected, the limbs about to become paralytic are troubled with pricking, tingling, numbness, weakness, and cramp. These local ailments progressively increasing, the limbs at length become decidedly paralytic, and the paralytic state having continued for an indefinite period, an apoplectic paroxysm supervenes, often preceded and denoted by spasms or convulsions in the unparalysed limbs. The coma, which forms a part of the apoplectic paroxysm, sometimes comes on gradually, and is manifestly progressive in intensity, the patient at first being capable of giving a coherent answer when strongly roused, but by degrees the loss of sensation becomes more and more complete, until at last the stupor passes into a state of total insensibility, from which there is no recovery. Now and then the patient recovers from the apoplectic state, and slowly regains the condition he was in previously to the apoplectic attack; more frequently, on the contrary, the paralytic affection increases, and another apoplectic seizure quickly supervenes, which proves mortal.

In some cases the morbid appearances that present themselves on inspection of the brain after death from this variety, differ in no respect from those which have been described as belonging to the preceding form; but the most frequent and characteristic morbid change is the softening of some portion of the substance of the brain. This softening of the cerebral substance is the result of inflammation, which is generally not acute in its nature, and is slow in its progress. The vessels belonging to this softened portion lose their vitality, and allow the red particles of the blood to pass through them, so that the part morbidly changed is not only soft but red, from the infiltration of blood through the diseased blood-vessels.

From this account of the phenomena of the disease, and of the morbid changes apparent in the brain in fatal cases, we are enabled to form an accurate conception of the pathological condition of the brain in apoplexy. Two of the conditions essential to the performance of the functions of the brain, are a supply of a certain quantity of blood, flowing with a certain impetus, and freedom from pressure. Without a certain portion of blood flowing with due impetus, the functions of the brain fail; with more than a certain portion, or with the velocity of the current quickened or retarded beyond a certain point, they equally fail; and when the pressure induced by either of these states exceeds a certain degree, they also immediately cease. The substance of the brain is tender and delicate, and abounds beyond all other organs with blood-vessels. It is of a soft and yielding nature, but it is inclosed in a firm, unyielding case. Coupling this fact with the phenomena of the circulation, it is easy to conceive how almost its entire mass, and still more readily how particular portions of it, may become subject to undue pressure, and how, as an inevitable consequence, the functions of the brain may become deranged. Any cause which quickens or which retards the circulation through it may produce this effect: for example, a preternatural distension of the arteries with blood, or a preternatural intensity in their action, and a consequent increased impetus of the circulation; or, on the contrary, a relaxation of the veins, a preternatural turgescence of them from a too great quantity of blood poured into them, and a consequent retardation of the circulation through them. Either from a too great velocity or intensity of the circulation in the arterial vessels, or from too great distension of the veins in consequence of an impeded flow of the blood through them, the thinner portion of the blood or serum may be poured out upon the brain, which in this manner may become subject to undue pressure. In consequence of either of these diseased states, the coats, whether of the arteries or veins, may suddenly give way and break, and the blood poured out upon the brain from the ruptured vessels may exert such a pressure upon it as instantly to destroy its functions. Again, tumours occasionally form in the brain, which progressively increase in magnitude, and at length exert such a degree of pressure upon the cerebral substance, as is no longer compatible with the performance of its functions. Disease of the heart also is known to affect the circulation in the brain, and is present in a large number of apoplectic cases.

Prognosis.—When once an attack has come on, even though it be slight, it places the individual in imminent danger; both because it greatly increases the predisposition to a recurrence of the paroxysm, and because, when it does not destroy life, it gives a shock to the constitution which is seldom entirely repaired, and never without much time and most judicious management. In the paroxysm the immediate danger is proportioned to the profoundness of the coma, the degree of stertor, the slowness and laboriousness of the respiration, and the frequency and intermission of the pulse. Other unfavourable signs are, delirium, convulsions, paralysis, involuntary and unconscious discharge of the urine and fæces, and above all, the continuance of the paroxysm without material diminution of its severity after the judicious employment of powerful remedies. When the respiration is exceedingly slow and laborious—when the pulse sinks to such a degree than it can be scarcely felt, and when the head, chest, and limbs are covered with a cold, clammy sweat, dissolution is near. On the other hand, the favourable signs are, mildness of the paroxysm, diminution of the symptoms after the exhibition of the appropriate remedies, and more especially restoration to consciousness, return of the power of voluntary motion, with a calm and soft pulse, a gentle, warm, and general perspiration, and a spontaneous flow of blood from the nose, the rectum, and so on.

Causes.—The causes of the disease are either predisposing or exciting. The *predisposing* causes are: 1. Sex. It is decidedly more common in the male than in the female, because the male is more exposed to the exciting causes, and nothing so surely generates a predisposition to the disease, as the long-continued operation of an exciting cause. 2. Age. It may occur in childhood and youth: it is indeed rare in the former, but it is not uncommon in the latter; still, however, the great majority of cases without doubt occur at the more advanced stages of life. The period commonly conceived to be that in which it most frequently occurs, is the interval between forty and seventy. Out of sixty-three cases, two were between twenty and thirty years of age; eight from thirty to forty; seven from forty to fifty; ten from fifty to sixty; twenty-three from sixty to seventy; twelve from seventy to eighty; and one from eighty to ninety years. 3. Conformation of the body. The large head, short neck, full chest, sanguine and plethoric temperament, have from time immemorial been considered as forming the apoplectic constitution; and though the disease may and often does occur in the very opposite states of the system, yet there cannot be a question that the conformation of the body just described is peculiarly favourable to the formation of that pathological condition of the brain on which, as we have seen, the malady depends. 4. Mode of life. Luxurious living, especially combined with sedentary habits, is a most powerful predisposing cause. 5. Suppression of accustomed evacuations, namely, the suppression of the piles or of discharges from the skin, whether from the sudden disappearance of eruptions, the result of natural disease, or the drying up of a seton or issue. 6. Mental states. Violent emotion: cases continually occur in which persons drop down suddenly in a fit in a paroxysm of anger. Long-continued anxiety is almost as powerful an exciting cause as luxurious living. It is the common opinion that the studious are more prone to this disease than other classes; but this notion is ill-founded, for the evidence is complete that moderate intellectual labour is not only in a high degree conservative of the general health, but that it is more especially preventive of that peculiar condition of the brain on which apoplexy depends. The condition of all others most conducive to apoplexy is that in which at a somewhat advanced age the food habitually taken is large in quantity and rich and stimulating in quality, at the same time that the intellectual faculties are little excited; while the history of lawyers, judges, and philosophers would indicate a remarkable exemption from this disease in all its forms. To these predisposing causes may be added disease of the heart, and a degeneration of the blood-vessels of the brain.

The predisposing causes, of whatever nature, act either by favouring an habitual determination of blood to the brain, or by impeding its return from this organ, or by impairing its vital energy, while they favour a plethoric state of its vessels. Such a condition of the brain having been formed, the slightest exciting cause is often sufficient to produce an attack.

Among the most powerful *exciting* causes are intemperance in eating and drinking, violent emotions of mind, whatever determines the blood with undue impetus to the brain or impedes its return from it, such as great muscular exertion, dependent posture of the head, tight ligature around the neck, the use of the warm bath, and the like.

Both sets of causes, the predisposing and the exciting, bring about a paroxysm either by diminishing the vital energy of the brain, or by producing undue pressure on its substance.

Treatment.—The treatment of this disease must obviously vary with the pathological condition of the brain on which it depends. The skill of the physician consists in detecting what that pathological condition is, and in exactly adapting his remedies to it, which must differ widely, according as he is called to treat a threatening or an actual paroxysm, or to prescribe for a patient subsequent to an attack. To enter into a discussion of the different remedies suited to the manifold states of the brain, and of the system, in the various forms and stages of this malady, would require a larger space than can be allotted to it in this work. There are not many parts of his science in which the physician is required to make such nice and difficult distinctions, and in which life so completely depends on the accuracy of his discrimination. At one time the vital energy of the brain is so far exhausted as of itself to threaten the total abolition of its functions; at another time the arterial action or the venous congestion is so great as to threaten an immediate effusion of serum or a large extravasation of blood. For states so opposite, opposite remedies must of course be required; but the difficulty at all times is to interpret the outward signs aright. If, together with the premonitory symptoms which have been enumerated, namely, drowsiness, giddiness, headache, and so on, there be a flushed countenance, a dull or suffused eye, a hot skin, a strong or full pulse, the abstraction of blood may be indispensable to the preservation of life; but if, on the other hand, the countenance be pallid and sunk, the pulse full, and the skin cool, the smallest blood-letting may utterly exhaust the vital energies of a brain already greatly depressed, and the only chance of averting death may be the judicious employment of stimulating remedies. It is in clearly pointing out distinctions like these, and in guiding to the selection of the remedy appropriate to each, that science is the salvation of life. But such too are precisely the cases in which no skill on the part of the physician can succeed without the steady co-operation of the patient. The physician duly weighing the premonitory signs may foresee the impending danger, and give warning of it, and prescribe precisely the medicine and REGIMEN fitted to avert it; but if these are either altogether neglected, or only partially followed, the disease will hold on its course and life be lost. And this loss of life is deplorably frequent from the neglect on the part of the patient of the appropriate remedies in the primary stage of the disease, when such remedies may be employed with almost certain success; and the same is true from the neglect of such remedies in the stage subsequent to an apoplectic paroxysm, although in this stage the best-concerted measures have a much less chance of securing their object.

It is only necessary to add here, that whenever a person is seized with a fit of apoplexy, he should be carried into a large room, the freest possible circulation of fresh air should be promoted around the body, which should be placed in the horizontal posture, with the head, however, considerably raised, all bandages should be taken from about the head and neck, and especially from about the neck; and a medical man should be sent for instantly. Every observer of such a case should bear in mind that the loss of life may be the consequence of the loss of a minute.

APOSEPIDINE. [LEUCINE.]

APOSTLES (ἀπόστολοι, messengers, ambassadors, missionaries) were according to Luke vi. 13–16, those twelve disciples whom Jesus chose from the number of his followers to be his companions, and whom he commissioned to preach his doctrines, first among the Jews only (Matt. x. 5; Luke ix. 2), and after his resurrection to the Gentiles also (Matt. xxviii. 19; Mark xvi. 15). Jesus said concerning apostles, "As my Father hath sent me, even so send I you. He breathed on them and said, Receive ye the Holy Ghost. Whose soever sins ye remit, they are remitted unto them; and whose soever sins ye retain, they are retained." (John xx. 21–23.) The list of the apostles occurs Matt. x. 2; Mark iii. 16, &c.; Luke vi. 14, &c. The names of the apostles are, "Simon, who is called Peter, and Andrew, his brother; James, the son of Zebedee, and John, his brother; Philip and Bartholomew; Thomas, and Matthew, the publican; James, the son of Alpheus; and Lebbeus, whose surname was Thaddeus; Simon the Canaanite; and Judas Iscariot, who also betrayed him." After the death of Judas Iscariot, 120 disciples being assembled, Peter recommended the choice of another apostle. "Of these men which have companied with us all the time that the Lord Jesus went in and out among us, beginning from the baptism of John, unto that same day that he was taken up from us, must one be ordained to be a witness with us of his resurrection. And they appointed two, Joseph, called Barsabas, who was surnamed Justus, and Matthias. And they prayed, and said, Thou, Lord, which knowest the hearts of all men, show whether of these two thou hast chosen, that he may take part of this ministry and apostleship, from which Judas by transgression fell, that he might go to his own place. And they gave forth their lots, and the lot fell upon Matthias; and he was numbered with the eleven apostles." (Acts i. 15–26.) To these twelve apostles was afterwards added Saul, whose name among the Greeks was Paul, called to be an apostle of the Gentiles through the will of God. (Gal. i. 1; Col. i. 1; Rom. xi. 13; Acts ix.) By the instrumentality of St. Paul, the Gospel was most effectually propagated. Barnabas (Acts xiv. 14), being an apostolic missionary, is mentioned in the following manner:—"And when the apostles Barnabas and Paul heard," &c. From this passage we infer that the title *apostle* was not exclusively given to the immediate disciples of Jesus. (Comp. Acts xiv. 4; Rom. xvi. 7.)

APOSTLES, ACTS OF. [ACTS OF THE APOSTLES.]

APOSTOLIC FATHERS are those teachers of the Christian Church who distinguished themselves during the first two centuries, and derived their Christian knowledge from personal acquaintance with the apostles, such as Barnabas, Clemens Romanus, Ignatius of Antiochia, Hermas, and Polycarpus, of whom notices will be found in the BIOGRAPHICAL DIVISION of the ENGLISH CYCLOPÆDIA.

APOSTO'LICI, were imitators of the apostolic life mentioned by Epiphanius. ('Hæres.' 67.) In the middle ages they were called Cathari. Some of them indulged Manichæan speculations, and others distinguished themselves only by their obedience to the moral doctrine of the New Testament. The latter, called Apostolic Brothers, were very numerous on the banks of the Lower Rhine, about the middle of the 12th century. We learn from a letter written A.D. 1146, in which Everwin, ecclesiastical provost of Steinfelden, exhorts St. Bernhard, of Clairvaux, to confute these heretics, that they rejected oaths, infant baptism, fasts, ceremonies, worship of saints, purgatory, masses, second marriages, the power of the pope, &c. Some of them were brought before the ecclesiastical court of the archbishop of Cologne, and defended themselves by biblical quotations. After a disputation of three days, being still unconverted, the people dragged them to the flames, in which they died manfully.

Another apostolic brotherhood was founded by Gerhard Sagarelli of Parma, about A.D. 1260. This brotherhood Pope Nicolas IV. endeavoured to suppress by various decrees of 1286 and 1290. Nevertheless Sagarelli and his adherents spread through Italy, Germany, France, and Spain. They went about accompanied by women singing, and preaching especially against the corruptions of the clergy. In 1294, two brothers and two sisters were burnt alive at Parma. Sagarelli abjured his heresy, but was burnt in 1300 for having relapsed. From this time Dolcino of Milan became the head of this party, who predicted the sudden downfall of the Romish church. Dolcino divided the development of Christianity into four dispensations, the last of which began with his apostolic order. Dolcino escaped from the inquisitors into Dalmatia, but returned to Italy in 1304. He fortified, with 1400 followers, a mountain in the diocese of Novara, near the village Balmara, and plundered, for his support, the adjacent country. In 1306 he fortified the mountain Zebello, in the diocese of Vercelli, and fought against the troops of the bishop, until he was compelled by famine to surrender in 1307. Dolcino and his companion Margaretha of Trent, were burnt with many of their followers. These Apostolici rejected the authority of the Pope, oaths, capital punishments, &c. Some Apostolic Brothers are mentioned A.D. 1311, near Spoleto; and A.D. 1320, in the south of France. The synod of Lavaur, 1368, mentions them for the last time.

APO'STROPHE (ἀποστροφή). A turning away, "a sudden change in our discourse, when, without giving previous notice, we address ourselves to a person or thing different from that to which we were addressing ourselves before." (Beattie, 'Elements of Moral Science.') The term is also used, less properly, for an address to some absent or inanimate object, as in 'Julius Cæsar,' Act iii. Sc. I.

> O pardon me, thou bleeding piece of earth,
> That I am meek and gentle with these butchers.

It is also used to express the contraction or division of part of a word, as *boro'* for *borough*, *learn'd* for *learned*. This practice of division, intolerable in a language already overburdened with consonants, was much more frequent in the writers of a century, or a century and a half ago, than now; and seems to have been affected to give an air of negligence and familiarity to their style. It ought seldom to be used except in verse, and very sparingly there. The comma, by which the final *s* of the genitive case is separated from the word, is also called an apostrophe, as in "Israel's monarch."

APOTHECARIES, COMPANY OF, one of the incorporations of the city of London. In England, in former times, an apothecary appears to have been the common name for a general practitioner of medicine, a chief part of whose business it was, probably in all cases, to keep a shop for the sale of medicines. In 1345, a person of the name of Coursus de Gangeland, on whom Edward III. then settled a pension of sixpence a day for life, for his attendance on his Majesty some time before while he lay sick in Scotland, is called in the grant, printed in Rymer's 'Fœdera,' an apothecary of London. But at this date, and for a long time after, the profession of physic was entirely unregulated. It was not till after the accession of Henry VIII. that the different branches of the profession came to be distinguished, and that each had its province and particular privileges assigned to it by the law. An Act of Parliament was passed in the third year of that king (1511), by which, in consideration, as it is stated, of "the great inconvenience which did ensue by ignorant persons practising physic or surgery, to the grievous hurt, damage, and destruction of many of the king's liege people," it was ordered that no one should practise as surgeon or physician in the city of London, or within seven miles of it, until he had been first examined, approved, and admitted by the Bishop of London, or the Dean of St. Paul's, who were to call in to assist them in the examination, "four doctors of physic, and of surgery other expert persons in that faculty." In 1518, the physicians were for the first time incorporated, and their college founded, evidently with the view that it should exercise a general superintendence and authority over all the branches of the profession. In 1540, the surgeons were also incorporated and united, as they continued to be till the beginning of the present century, with the barbers. The two associations thus established appear, however, to have very soon begun to overstep their jurisdiction. It was found necessary, in 1543, to pass an Act for the toleration and protection of the numerous irregular practitioners, who did not belong to either body, but who probably formed the ordinary professors of the healing art throughout the kingdom. In this curious statute, the former Act of 1511 is declared to have been passed, "amongst other things, for the avoiding of sorceries, witchcraft, and other inconveniences;" and not a little censure is directed against the licensed and associated surgeons for the mercenary spirit in which they are alleged to have acted, while much praise is bestowed upon the unincorporated practitioners for their charity in giving the poor the benefit of their skill and care, and for the great public usefulness of their labours generally. The import of the enactment is expressed in its title, which is, "An Act that Persons being no common Surgeons may minister outward Medicines." The persons thus tolerated in the administration of outward medicines, of course comprehended those who kept shops for the sale of drugs, to whom the name of apothecaries was now exclusively applied. The acceptation of the name, as thus confined, may be gathered from Shakspere's delineation of the apothecary in 'Romeo and Juliet' (published in 1597), as one whose business was "culling of simples," who kept a "shop," the "shelves" of which were filled with "green earthen pots," &c., and who was resorted to as a dealer in all sorts of chemical preparations.

It is evident, however, that persons dealing in drugs and simples, who would thence be supposed to know more of their qualities than their neighbours, must have been often applied to for advice. There is a curious chapter, added to an edition of R. Recorde's 'Urinal of Physik,' stated to have been written in the reign of Elizabeth, by a physician. and bearing the date, apparently as a reprint, of 1662. The title of the book is, 'A Detection of some Faults in Unskilful Physicians, ignorant and careless Apothecaries, and unknown running Chirurgeons.' After some complaints of unlearned physicians, he gives 'seven articles,' which he had submitted to the Bishop of Salisbury, in which city he dwelt, for the reformation of matters. The first is, that no physician be allowed to practise without a licence from some university or the bishop of the diocese. The second is, "that no chirurgeon should practise his chirurgery unless he could read and write, and have knowledge of the simples belonging to his art. And that he presume not to let blood, or undertake any hard cure, without the physician's counsel, if he may conveniently have it." This "chirurgeon" seems not to differ much from a general practitioner. The third article recommends that no apothecary be permitted to "minister of his own head, or ordain any purgation or other composition of physic for any man." The remaining articles recommend that a court of physicians should examine, convict, and punish any offenders against these regulations. According to the physician's own account, the apothecaries—perhaps, however, only in Salisbury—took very high ground, and had their pretensions recognised by at least some physicians. He says, "What maketh many apothecaries now-a-days to set so little by the physician? This is one chief cause: they play the physicians themselves; they give and minister medicines of their own device (God wot a mad device) indifferently unto all men; yea, and the more ignorant they are, the bolder they be; for who is so bold as blind Bayard? Many of them will not stick to look in waters, and not be ashamed, even in the physician's presence, to ordain this or that medicine for any kind of disease. If any physician do gently admonish them of the faults, and specially of giving medicines after their own brain, they will say that they may as well prescribe medicines as physicians do sometimes use to make them." He adds, in another part of his account of the apothecaries, "it were good also that no kind of poison should be pounded or dissolved in any mortars occupied daily for the shop, for thereof hath chanced much evil." Carelessness, it would seem, is not the growth of to-day.

The apothecaries of London were at length incorporated by James I. on the 9th of April, 1606, and united with the Company of Grocers. They remained thus united till the 6th of December, 1617, when they received a new charter, forming them into a separate company, under the designation of the Master, Wardens, and Society of the Art and Mystery of Apothecaries of the City of London. This is the charter which still constitutes them one of the city companies, although various subsequent Acts of Parliament have materially changed the character of the society.

It appears to have been only a few years before the close of the 17th century, that the apothecaries, at least in London and its neighbourhood, began generally to prescribe, as well as to dispense medicines. This encroachment was strongly resisted by the College of Physicians, who, by way of retaliation, established a dispensary for the sale of medicines to the poor at prime cost, at their hall in Warwick Lane. A paper controversy of great animation rose out of this measure; but the numerous tracts which were issued on both sides are now all forgotten, with the exception of Garth's burlesque epic poem, entitled 'The Dispensary,' first published in 1697. The apothecaries, however, may be considered as having made good the position they had taken; although for a considerable time their pretensions continued to be looked upon as of a somewhat equivocal character. In 1703, the House of Lords decided, in the case of William Rose (we quote from the 'London Journal of Medicine' for May, 1850), "that the duty of an apothecary consisted not only in compounding and dispensing, but also in directing and ordering the remedies employed in the treatment of disease."

Addison, in the 'Spectator,' No. 195, published in 1711, speaks of the apothecaries as the common medical attendants of the sick, and as performing the functions both of physician and surgeon. After mentioning blistering, cupping, bleeding, and the inward applications employed as expedients to make luxury consistent with health, he says, "The apothecary is perpetually employed in countermining the cook and the vintner." On the other hand Pope, in his 'Essay on Criticism,' published the same year, has the following lines in illustration of the domination which he asserts to have been usurped by the critic over the poet:—

> 'So modern 'pothecaries, taught the art
> By doctors' bills to play the doctor's part;
> Bold in the practice of mistaken rules,
> Prescribe, apply, and call their masters fools.'

Nor, indeed, did the apothecaries themselves contend at this time for permission to practise as medical advisers and attendants any further than circumstances seemed to render it indispensable. In a cleverly written tract in their defence, published in 1724, and apparently the production of one of themselves, entitled 'Pharmacopolæ Justificati; or the Apothecaries vindicated from the Imputation of Ignorance, wherein it is shown that an Academical Education is nowise necessary to qualify a man for the Practice of Physic,' we find the following opinion expressed (p. 31), "As to apothecaries practising, the miserable state of the sick poor, till some other provision is made for their relief, seems sufficiently to warrant it, so long as it is confined to them." We may here observe, that the custom of persons being licensed by the bishops to practise medicine within their dioceses continued to subsist at least to about the middle of the last century. It is exclaimed against as a great abuse in a tract entitled 'An Address to the College of Physicians,' published in 1747.

It has been stated in various publications, that the order of dealers in medicines, known as chemists or druggists, first made their appearance about the end of the last century. As they very soon began to prescribe as well as to dispense, the rivalry with which they were thus met was as eagerly opposed by the regular apothecaries, as their own encroachments had in the first instance been by the physicians. In certain resolutions passed by a meeting of members of the Apothecaries' Company on the 20th of November, 1812, among other causes which are asserted to have of late years contributed to degrade the profession, is mentioned the intrusion of pretenders of every description; "Even druggists," it is said, "and their hired assistants, visit and administer to the sick; their shops are accommodated with what are denominated private surgeries; and, as an additional proof of their presumption instances are recorded of their giving evidence on questions of forensic medicine of the highest and most serious import!" But in all this the druggists really did no more than the apothecaries themselves had begun to do a hundred years before. We doubt, too, if the first appearance of these interlopers was so recent as has been assumed. We find a tract, printed on a single folio leaf 'at the Star in Bow Lane in 1683,' entitled 'A Plea for the Chemists or Non-Collegiats,' in which the author, Nat Merry, stoutly defends the right of himself and the other manufacturers of chemical preparations to administer medicines, against the objections of the members of the Apothecaries' Company, who seem to have been themselves at this time only beginning to act as general practitioners. And in 1708, we find a series of resolutions published by the Court of Apothecaries, in which they complain of the intrusion into their business of foreigners—that is, of persons not free of the company. Their charter, though it appeared to bestow upon them somewhat extensive privileges, had been found nearly inoperative from the omission of any means of executing its provisions, and of any penalties for their infringement. In 1722, therefore, an Act of Parliament was obtained by the company, giving them the right of visiting all shops in which medicinal preparations were sold in London, or within seven miles of it, and of destroying such drugs as they might find unfit for use. This Act expired in 1729; and although an attempt was made to obtain a renewal of it, the application was not persevered in. But in 1748 another Act was passed, empowering the Society to appoint ten of their members to form a Court of Examiners, without whose licence no one should be allowed to utter medicines in London, or within seven miles of it. It was stated before a Committee of the House of Commons, that there were at this time about 700 persons who kept apothecaries' shops in London, not one-half of whom were free of the company. But this Act probably had the effect of putting the unlicensed dealers down; which may account for the common statement, that no such description of dealers ever made their appearance till a comparatively recent period. In an Introductory Essay prefixed to the first volume of the 'Transactions of the Associated Apothecaries and Surgeon Apothecaries of England and Wales,' (8vo, London, 1823), in which it is admitted that anciently "the apothecary held the same situation which appertains, or ought to appertain, to the present druggist, who arose," it is affirmed, "about thirty years ago," the following remark is added: "For some time previous to that period, indeed, certain apothecaries existed, who purely kept shop, without prescribing for diseases: but very few of these existed even in London; for in the memory of a physician lately dead, there were not more, as he stated, than about half-a-dozen persons in London, who kept what could be called a druggist's shop."

Until a comparatively recent period the jurisdiction of the Company of Apothecaries did not extend beyond the metropolis and its immediate neighbourhood. But in 1815, an Act of Parliament was passed, which placed the Society in altogether a new position, by giving to the Court of Examiners, then increased to twelve members, the sole right of examining and licensing apothecaries throughout England and Wales. It was enacted, that after the 1st of August in that year, no person not so licensed should practise as an apothecary, except such only as were already in practice. It was also made imperative that candidates for examination should have previously served an apprenticeship of at least five years with a member of the company.

The history of the steps taken to procure this Act is very minutely detailed in the Essay prefixed to the 'Transactions of the Associated Apothecaries and Surgeons,' already referred to. The application was commenced, and indeed principally carried through, by this private society; the Colleges of Physicians and Surgeons, and the Apothecaries' Company themselves, having declined joining in it. The Act, however, fell in one material respect very far short of the design entertained by its projectors, inasmuch as the opposition of the chemists and druggests rendered it necessary to introduce a clause into it exempting that class of dealers altogether from its operation.

From the circumstance that in country places, with very few exceptions, no person can practise medicine without keeping a supply of drugs for the use of his patients, or in other words, acting as an apothecary, this statute gave to the Society of Apothecaries the complete control of the medical profession throughout England. Every general practitioner had not only to purchase his licence, but to serve a long apprenticeship with a member of the company. The price of a licence to practise in London or within ten miles of it, was ten guineas, and in any other part of the country, six guineas. The penalty for practising without this licence was twenty pounds. It was expressly declared in the Act that the Society may appropriate the moneys which they thus receive in any way they may deem expedient.

It is right to state that the parties by whom the Act was sought, did not originally contemplate the giving of these extensive powers to the Apothecaries' Company. In one of their first reports, dated the 5th of December, 1812, the committee of management express themselves as of opinion "that the management of the sick should be as much as possible under the superintendence of the physician;" and it was then proposed that a new and a distinct privileged body should be created to examine and license practitioners, composed of members of all the different branches of the profession. This scheme, however, was abandoned when both the Colleges of Physicians and Surgeons refused to co-operate in getting it carried into effect.

Before this Act came into operation a large proportion of the medical practitioners in country places throughout England were graduates of the Universities of Edinburgh, Glasgow, and Dublin, or licentiates of the Royal Colleges of Surgeons of these cities, or of that of London, none of whom obtained their degrees or certificates without passing through a long course of study and a rigorous examination. Persons thus qualified were admitted as surgeons in the army and navy, and into the service of the East India Company; but they were no longer allowed to act as country practitioners in England. This privilege could only be obtained by a service of five years in the shop of a practitioner who was a member of the Company of Apothecaries, and by undergoing an examination in London before the Court of Examiners.

In April, 1835, the Court of Examiners issued new regulations for raising still higher the qualifications of candidates for the licence of the company, and it has been further raised at intervals since. Every candidate whose attendance on lectures commenced on or after the 1st of October, 1858, must now have attended the following lectures and medical practice during not less than three winter and two summer sessions: each winter session to consist of not less than six months, and to commence not sooner than the 1st nor later than the 15th October; and each summer session to extend from the 1st of May to the 31st of July.

First Winter Session.—Chemistry, anatomy, and dissections.

First Summer Session.—Materia medica and therapeutics, botany, and practical chemistry, which is to include a specific course of instruction in the laboratory, and an opportunity of acquiring a knowledge of the various reagents for poisons.

Second Winter Session.—Anatomy, physiology, dissections, principles and practice of medicine, and clinical medical practice, which must be attended during the full term of eighteen months; twelve months in an hospital connected with a recognised medical school, and six months at a recognised hospital or dispensary, if more convenient.

Second Summer Session.—Clinical practice of medicine, with the same conditions as in the winter session; midwifery, and diseases of women and children, with attendance on not less than twenty cases; forensic medicine and toxicology; and demonstrations on morbid anatomy.

Third Winter Session.—Clinical lectures, seventy-five, which may be commenced in the second summer session, but the attendance must be certified; clinical medical practice, as before; and demonstrations on morbid anatomy.

The above course of study may be extended over a longer period than three winter and two summer sessions, provided the lectures and medical practice are attended in the prescribed order and in the required sessions. The examination of candidates for certificates to practise as apothecaries is divided into two parts. The first examination, which may be passed after the second winter session, if the candidate has completed his nineteenth year, embraces Latin, including the pharmacopœia and physicians' prescriptions; anatomy; physiology; general and practical chemistry; botany; and materia medica. In the second, after the third winter session, the five years' pupilage being completed, the subjects are: practice of medicine and pathology; midwifery, including the diseases of women and children; and forensic medicine and toxicology. For a certificate of qualification to act as an assistant to an apothecary in compounding and dispensing medicines, the examination will be in translating physicians' prescriptions, and the 'Pharmacopœia Londinensis'; and in pharmacy and materia medica.

In the statement issued by the Company of Apothecaries in May, 1844, they say: "The increased number of medical students attending lectures in conformity with the regulations led to the increase of medical teachers, and not only did new schools spring up in the metropolis, but, under the auspices of the Court of Examiners, public schools of medicine were organised in the provinces: and at the present day Manchester, Liverpool, Birmingham, Leeds, Bristol, Hull, Sheffield, Newcastle, and York, have each their public school, at which the student may pursue and *complete* his medical education." It is added that "no mean proportion of those whose examination has given evidence of the highest professional attainment, have been pupils of the provincial schools." The influence of the regulations of the Court of Examiners on the medical profession is very great. The opinion of very eminent members of the medical profession before a select committee of the House of Commons in 1834, as to the manner in which the Apothecaries' Company had performed the duties devolving upon them as an examining body, is decided in its approbation.

Notwithstanding this reform, a strong feeling of dissatisfaction continued to prevail in many quarters, at the exclusion from the right to practise of all persons except those who have served an apprenticeship of five years with an apothecary, and a bill was brought into the House of Commons in 1832 to remove this disability. It was withdrawn in consequence of some difference of views as to a minor point among the parties by whom it was promoted. The object was not to take the right of examination and licence from the Court of Examiners of the apothecaries, but to permit the licentiates of the Scotch and Irish Universities, and of the Colleges of Surgeons, to practise in England, as well as those who have the diploma of the Apothecaries' Company.

From this time the agitation for a reform of the regulations respecting the professors of medicine was almost incessantly continued.

In almost every session of Parliament a bill, and sometimes more than one, was introduced for this purpose; but the difficulty of reconciling the various views of the three branches of physicians, surgeons, and apothecaries, prevented any of them from becoming law. At length, in 1858, an Act was passed (21 & 22 Vict. cap. 90), by which a Medical Council was appointed for the whole of the United Kingdom, to consist of one person chosen from each of the following bodies: The Royal Colleges of Physicians and Surgeons of London; the Apothecaries' Society of London; the Universities of Oxford, Cambridge, Durham, and London; the Colleges of Physicians and Surgeons of Edinburgh; the Faculty of Physicians and Surgeons of Glasgow; the Universities of Aberdeen and Edinburgh (one); the Universities of St. Andrew's and Glasgow (one); the King's and Queen's College of Physicians in Ireland; the Royal College of Surgeons in Ireland; the Apothecaries' Hall of Ireland; the University of Dublin; the Queen's University in Ireland; and six persons (four for England, and one each for Scotland and Ireland) to be nominated by Her Majesty in Council. This Medical Council were chosen or nominated for five years, with provision for filling up vacancies, and to them were entrusted the power of examining candidates for the practice of medicine, to whom they are to award certificates according to their qualifications, and in the department they have chosen. The Council are empowered, in order to afford facilities for examination, to appoint Branch Councils, to whom are deputed full functions for examining and granting certificates in various localities, and such have been appointed in Edinburgh and Dublin. Every person receiving a certificate is to have his name and qualification published in an annual register, and only such as are registered are capable of filling any medical office in the army or navy, or in any hospital or infirmary, or of medical officer to a Poor Law Union; and unless so registered, cannot recover in a court of law any charge for medicine or attendance, which, if registered, he is enabled to do; and no certificate, as from a medical practitioner, is to be valid, unless such practitioner is registered. All persons on the register are empowered to practise in any part of the United Kingdom or the colonies, according to the qualification in the register. The General Council have the right of prescribing the course and degree of stringency in the examination, and may interfere to prevent candidates being accepted from places where a proper course of previous study has not been pursued. Persons on the register are exempted from serving on juries, from all corporate, parochial, ward, hundred, and township offices, and from serving in the militia. Fees are payable on examination and being placed on the register, and penalties are imposed upon fraudulently procuring admission on the register, or for falsely pretending to be on it. The General Council are also to cause to be compiled, and to publish, a 'British Pharmacopœia,' "with a list of medicines and compounds, and the manner of preparing them, and the true weights and measures by which they are to be prepared and mixed." But nothing in the Act is to apply to the trades of chemists and druggists or of dentists.

The Apothecaries rank as the fifty-eighth in the list of City companies. Their arms are, azure, Apollo in his glory, holding in his left hand a bow, in his right an arrow, bestriding the serpent Python; supporters, two unicorns: crest, a rhinoceros, all *or*; motto, "Opiferque per orbem dicor." They have a hall in Water Lane, Blackfriars, at which medicines are sold to the public; and where all the medicines are prepared that are used in the army and navy. They also possess a garden, to which every medical student in London is admitted, of above three acres in extent, at Chelsea, in which exotic plants are cultivated. The ground was originally devised to them, in 1673, for sixty-one years at a rent of five pounds, by Charles Cheyne, Esq., lord of the manor of Chelsea, and afterwards granted to them in perpetuity, in 1721, by his successor Sir Hans Sloane, on condition that they should annually present to the Royal Society, at one of their public meetings, eighty specimens or samples of different sorts of plants, well-cured and of the growth of the garden, till the number should amount to two thousand. This they have done, and the specimens are preserved by the Royal Society. They still observe an old custom of making every summer a number of herbalizing or simpling excursions to the country, which are now, we believe, so conducted as to be valuable botanical lessons to the apprentices or pupils by whom the members of the society are accompanied on these occasions. The society gives every year a gold and a silver medal to the best-informed students in botany, who have attended their garden.

APOTHEO'SIS (ἀποθέωσις, a deification, literally, a god-making), the enrolment of a mortal among the gods. The mythology of Greece is full of instances of this: it is sufficient to call to mind Minos, Hercules, and other heroes, who received divine honours. It was one of the doctrines of Pythagoras, that good men after death were raised into the order of gods. To exalt fellow-men to this extent, however, was foreign to the disposition of republican states; and, therefore, though the Greeks always held in high respect the heroes of ancient times, we hear of no deifications from the time when a republican form of government became prevalent in Greece, until the spirit of independence was broken, and the Greeks became as obsequious to kings and princes, as they had formerly been unbending. There is, however, an example to the contrary recorded by Herodotus (v. 47): The people of Egeste built an *heroum* to Philippus, though he fell in battle against them, and offered sacrifices to him, as Herodotus himself testifies; it was on account of his beauty that he was deified. Alexander, according to some rather doubtful stories, not only claimed divine parentage, but a divine nature while on earth; and the compliment of deification was commonly paid to the princes of the various dynasties who succeeded to his empire. On the coins of the Seleucidæ we often find the word "God" (Θεός). In Rome, also, we find Romulus raised to the rank of a god; but there are no instances of Romans admitted to the rank of deity, from the expulsion of Tarquin, until the empire of the Cæsars. Julius Cæsar was worshipped as a god after his murder. Augustus, while yet alive, was declared the tutelary god of all the cities of the empire, and the succeeding emperors after death were enrolled among the numerous tenants of heaven. It is to the death and reception of Julius Cæsar into heaven, that the 5th Eclogue of Virgil is by some supposed to refer.

The term *Apotheosis*, however, is more especially used to signify the ceremony by which the Roman emperors were admitted, if we may use the expression, after death to divine honours. This is minutely described by Herodian (lib. iv. c. 3), and the passage presents so curious a picture of the absurdities into which an idolatrous religion betrayed its votaries, that we translate it here: "It is the custom of the Romans to deify those of their emperors who die, leaving successors; and this rite they call *apotheosis*. On this occasion, a semblance of mourning, combined with festival and religious observances, is visible throughout the city. The body of the dead they honour after human fashion, with a splendid funeral; and making a waxen image in all respects resembling him, they expose it to view in the vestibule of the palace, on a lofty ivory couch of great size, spread with cloth of gold. The figure is made pallid, like a sick man. During most of the day senators sit round the bed on the left side, clothed in black; and noble women on the right, clothed in plain white garments, like mourners, wearing no gold or necklaces. These ceremonies continue for seven days; and the physicians severally approach the couch, and, looking on the sick man, say that he grows worse and worse. And when they have made believe that he is dead (ἐπὰν δὲ δόξῃ τετελευτηκέναι), the noblest of the equestrian and chosen youths of the senatorial orders take up the couch, and bear it along the Via Sacra, and expose it in the old forum. Platforms like steps are built on each side: on one of which stands a chorus of noble youths, and on the opposite, a chorus of women of high rank, who sing hymns and songs of praise (ὕμνους καὶ παιᾶνας) to the deceased, modulated in a solemn and mournful strain. Afterwards they bear the couch through the city to the Campus Martius; in the broadest part of which, a square pile is constructed entirely of logs of timber of the largest size, in the shape of a chamber, filled with faggots, and on the outside adorned with hangings interwoven with gold and ivory images and pictures. Upon this, a similar, but smaller chamber is built, with open doors and windows, and above it, a third and fourth, still diminishing to the top, so that one might compare it to the light houses, which are called *Phari*. In the second story they place a bed, and collect all sorts of aromatics and incense; and every sort of fragrant fruit or herb or juice; for all cities and nations and persons of eminence, emulate each other in contributing these last gifts in honour of the emperor. And when a vast heap of aromatics is collected, there is a procession of horsemen and of chariots around the pile, with the drivers clothed in robes of office, and wearing masks made to resemble the most distinguished Roman generals and emperors. When all this is done, the successor to the empire applies a torch to the building; and others set fire to it on every side, which easily catches hold of the faggots and aromatics. And from the highest and smallest story, as from a pinnacle, an eagle is let loose to mount into the sky as the fire ascends; which is believed by the Romans to carry the soul of the emperor from earth to heaven: and from that time he is worshipped with the other gods." Compare with this description Dion's account (book 74), of the funeral ceremonies of Pertinax.

In conformity with this practice, it is common to see on medals struck in honour of an apotheosis, an altar with fire on it, and an eagle taking its flight into the air. Several representations of real or supposed apotheoses have been preserved in ancient gems and sculptures; of which the most celebrated is the apotheosis of Homer, formerly in the Colonna palace at Rome, but now in the Townley Gallery of the British Museum. This monument shows, in the lower compartment, the interior of a temple, and thence upwards the process of the apotheosis. This work of art has been illustrated by some of the most eminent of modern scholars. Montfaucon has published the apotheosis of Romulus in the third volume of the supplement to his 'Antiquities'; and there is an apotheosis of Augustus, on an onyx eleven inches by nine, in the Imperial Library at Paris.

APO'TOME, in ancient Greek music (from ἀπὸ, *from*, and τέμνω, *to cut*), the remainder of a whole tone when diminished by a *limma* [LIMMA], or smaller semitone, the ratios being 2187 and 2048. The Greeks were aware that the tone-major could not be rationally divided into two equal parts; they therefore divided it into a greater and less semitone, which they called *apotome* and *limma*, the difference whereof is a *comma*. [COMMA.] Under the heads TONE, and SCALE, MUSICAL, OF THE GREEKS, will be found further information concerning the ancient manner of dividing the octave.

APPARA'TUS SCULPTO'RIS, or the Sculptor's Workshop, a constellation formed by Lacaille. It is situated in that region of the heavens immediately to the eastward of the large star Fomalhaut, or a Piscis Australis, and hardly rises above the horizon in our hemisphere. It is bounded by Cetus and Aquarius on the north, Fornax Chemica on the east, Piscis Australis on the west, and Phœnix on the south. There are no bright stars in this constellation. The following is a classified enumeration of those which are visible to the naked eye :—

Magnitude	Number of Stars.
5	4
5·5	8
6	28
Total number of stars	40

APPARENT (in Astronomy). When it is necessary or convenient to reduce an observed phenomenon, either by clearing it of the effects of any optical delusion, or substituting for it the phenomenon which would have been observed at some more commodious station, that which is actually observed is called the *apparent* phenomenon, in opposition to that which results from correction or reduction, which is called the *real* or *true* phenomenon.

APPARENT MAGNITUDE, the angle under which any line appears at the eye; that is, the angle made by lines drawn from its extremities to the eye. [MAGNITUDE.]

APPARENT MOTION, the velocity and direction in which a body appears to move, when the spectator himself is in motion, without being conscious of it. For further detail see MOTION.

APPARITION. The mind affects the body; the body affects the mind; and some insight may be obtained into the disordered states of the mind, by considering the physical conditions which are necessary to sound thought.

It is not true, as is commonly supposed, that we see with the eye, and hear with the ear, and taste with the tongue. The true seat of these sensations is the brain, and the eye, the ear, the tongue, are organs adapted to receive impressions from external objects, which impressions are transmitted from the organs by an appropriate apparatus to the brain, where they become sensations. When an object is presented to an organ of sense, it produces a change in the nerves of that organ. This change is conveyed by the nerves to the brain; a corresponding change is occasioned in the brain, and through the brain in the mind; and it is this change in the mind which is expressed by the term sensation. Ideas, on the contrary, are copies of sensations, renovations of prior feelings, in general differing from sensations in being less intense.

The functions of the brain, then, are sensation, and, if the analogous term be allowed, ideation, together with the action and re-action of these two states on each other, known under the name of intellectual operation. The main instrument by which intellectual operation is carried on is what is termed association. It is a property of the mind to combine and unite the sensations and ideas it receives in such a manner, that, after this combination or union has been once formed, if any one of these sensations and ideas be revived, the single sensation or idea so revived will immediately call up to view all the sensations and ideas that had previously been connected with it; and this power of association, as long as its action is sound, is observed to operate in a uniform and determinate manner. For example, when sound, association excites ideas in a certain order, generally in the order of sensation. Thus, if the sensations A B C were impressed upon the mind in the order of those letters, B will re-excite not A, but C. Association, when sound, operates by exciting ideas with a certain degree of velocity. If the rapidity of the succession of the trains of ideas pass beyond a certain point, instead of distinct there is confused thought. Association, when sound, operates by exciting ideas with a certain degree of vivacity. Sensation is not produced, unless the external object be applied to the organ of sense with a certain degree of force; while, if propelled against it with too great an impetus, instead of specific sensation, it excites only pain. In like manner, unless the trains of ideas recalled by association possess a certain degree of vivacity, they present to the mind an indistinct assemblage of images; if, on the other hand, they are too vivid, they are equally incapable of forming the elements of sound thought.

In order that the brain may carry on these operations, that is, in order that it may receive the impressions conveyed to it by the nerves from the organs of sense, in order that it may convert these impressions into sensations, and in order that it may duly combine and revive them, it must be in a sound state. The chief agents which maintain the brain in a sound state are its organic nerves, and its circulating vessels. Like every other organ, the brain is maintained in a healthy condition by the process of nutrition. [NERVOUS SYSTEM, NAT. HIST. DIV.] Disease may take place in the substance of the brain, and this disease may assume a variety of forms far too great to be enumerated here, the slightest of which may be incompatible with the production of sound thought. If, on the other hand, the flow of blood through its circulating vessels be deranged, the process of thought may be equally disordered. Stop the flow of blood to the brain altogether, insensibility will follow instantly; fainting will supervene, and this state will be quickly succeeded by death, unless the vital current be re-admitted. Quicken the circulation beyond a certain point, insensibility equally follows; and, though the preternatural velocity of the circulation should stop short of inducing insensibility, it may yet disturb the ordinary process of thought in an infinite variety of modes.

Now there is scarcely a single disease which is not capable of disturbing, in a greater or less degree, the action of the organic nerves of the brain; but the maladies which most commonly and remarkably disturb the functions of these nerves, are certain diseases of the abdominal viscera, particularly of the alimentary canal, and more especially of that portion of it which forms the stomach; certain diseases of the liver, and of the mesenteric glands, and of the urinary and reproductive organs. In like manner excitation or depression of the action of the blood-vessels of the brain, beyond a certain point, uniformly disorders sensation and all the mental operations. Striking illustrations of both are afforded by the effect of many physical agents, as well as of natural diseases. Of the first, the effects of the inhalation of nitrous oxide affords an example. When nitrous oxide is received into the lungs, the pulse is increased in strength, fulness, and velocity. A corresponding change takes place in the mental impressions. Sensation becomes more vivid; the sensibility to touch increases; luminous points dazzle the eye; the hearing is more acute; recollections, generally of a pleasing nature, and of uncommon intensity, pass rapidly through the mind. One individual compares his feelings, under the influence of this gas, to those which he experiences when witnessing an heroic scene upon the stage; another likens them to the emotions he felt when, on the occasion of the commemoration held at Westminster Abbey in honour of Handel, he heard seven hundred instruments playing at one time.

The inhalation of ether, chloroform, and amylene, produces also analogous effects. These substances have, in fact, been employed to the extent of depriving the brain of its consciousness, so that it is no longer aware of external sensations, and suffers no pain. [ANÆSTHETICS.]

The inhalation of malaria, the poison which produces fever, affords an equally striking illustration of the modification of sensation, and of all the subsequent operations of the mind, by a cause affecting the nerves and blood-vessels of the brain. Febrile miasma is a depressing, nitrous oxide a stimulating, agent; the effect of the former on the brain ought therefore to be the reverse of the latter, and, accordingly, on receiving into the lungs the febrile miasma, the pulse becomes oppressed and weak; languor and lassitude pervade the limbs; the countenance becomes pale, the surface cold; headache, giddiness, and sometimes vomiting supervene, while the mind is feeble, dull, dejected, incapable of the effort of attention, and utterly unable to control or even to connect the trains of gloomy and distressing images which terrify the imagination. "Some circumstances had occurred," says a physician who carefully observed the phenomena which attended the progressive derangement of his own mind under the influence of fever, "to render me anxious and dispirited; of these I took an exaggerated and gloomy view. I had been studying during several months with unusual severity. One day in the cold weather of January, after having been occupied many hours in the practical duties of my profession, I returned home fatigued. Great as was my bodily exhaustion, the depression of my mind was still more remarkable. My head ached, and unable to study or to attend to any professional engagement, I lay on the sofa and attempted to read, chance having thrown in my way the American novel called the 'Water Witch.' I became interested in the story, but the pain and confusion of my head increasing, I requested a friend to read to me, my own eye continually wandering from the page. The progress of the fever was rapid; its chief force fell upon the organ that had been recently over-excited, the brain; and delirium came on early, and somewhat suddenly. Immediately before I became decidedly delirious, I received an invitation to the soirées given by the Duke of Sussex to the members of the Royal Society. The friend I asked to return an answer expressive of my regret that I should be unable to attend on account of illness, used, as I conceived, an expression not strictly correct: this verbal inaccuracy, I thought, was construed into wilful falsehood; the matter was brought before this assemblage of learned men, who unanimously declared that it ought to exclude me from the society of honourable men, and that I should no more be admitted amongst them. This announcement was brought me from the palace, accompanied with martial music, but of a more solemn and impressive kind than I had ever heard before, in which was predominant the sound of bells, soft, and as if of silver tone. Remonstrance was vain: the decision of which I succeeded in obtaining a reconsideration, was confirmed; this confirmation was brought me in the same manner as the first announcement, accompanied with the same kind of music, only still more solemn and impressive. I saw no person forming the band of musicians, but occasionally I heard very distinctly their measured step. I now thought myself an abandoned and lost being; and the apprehension that every one about me hated and sought occasion to destroy me, took possession of my mind. My physicians, my nurses, my dearest friends, were in league with a malignant spirit, which assumed the shape of the demon of the 'Water Witch.' By an object of my tender affection, who was anxiously watching over me, but in whom I now saw only the willing agent of the demon, I was betrayed, and through this treachery the malignant spirit obtained entire possession of me. No sooner was I in the power of the demon than she began to suggest to me the commission of crimes abhorrent to my nature, and at last there fixed upon my mind the impression that I had really been guilty of the crimes, by the vivid picture of which my imagination had been disturbed. I pass over the hurricanes and storms I encountered, evidently suggested by the descriptions in the novel I had just been reading: on the sudden subsidence of these I thought I stood before an invisible tribunal. I felt a solemn consciousness that an all-seeing eye was on me; while there was visible to me only a portion of the deck of the Water Witch, and very obscurely the shadow of my malignant accuser. Not the crimes falsely laid to my charge, but the actual events of my life, even the events of childhood and youth, long forgotten, were now called up with extraordinary vividness; all the circumstances of place, person, dress, language, and attitude, such as had actually accompanied them, being revived. Of each of these events I was compelled to give a true account, an invisible hand recording every syllable that fell from my lips, and a secret power obliging me to utter the words which expressed the exact truth. During this ordeal I saw the countenances of dear friends, and of secret and open enemies, those that had long been dead, as well as those that were still living; the former cheering me by their attitudes and words, the latter scowling upon me and assuming menacing postures, but uttering no sound. And now again I felt myself under the power of the demon, by whose uncontrollable agency I was compelled to accuse myself of the crimes of her own suggesting; and while suffering the bitter anguish of self-reproach, and expecting some fearful punishment, I again saw my dearest friends, with their innocent and happy countenances, engaged in occupations with which associations of a highly pleasurable nature had been formed in my mind, but whom I could not make sensible of my presence, and with whom I was doomed to hold affectionate intercourse no more. After this I have no remembrance of anything that passed, until conscious of the return of some obscure and vague recollections. I had the impression that some calamity had befallen me; but I felt as if a soft and refreshing breeze were blowing gently upon me; and soon I found myself in a vast ocean, in a beautifully-constructed vessel, with a fresh and invigorating breeze, sailing rapidly along a coast presenting the most magnificent and lovely scenery; and at length the vessel entered gallantly a port unknown to me, but the strand was crowded with human beings with happy faces, and still happier voices. I had returned from a long voyage, but I could not make out where I had been. I felt hungry and fatigued; and now, for the first time, I recognised the individuals of my family, after having been violently delirious upwards of a fortnight, during the last three days of which time I lay in a state of total insensibility, my physicians and friends expecting every moment to be the last."

Whoever will consider carefully the mental phenomena produced by the different and opposite conditions of the brain, the one produced by the operation of physical agents, the other arising under the influence of disease, will have no difficulty in conceiving the origin of spectral illusions, either with the consciousness that they are illusions, or with a temporary or permanent persuasion that they are real existences, and whether arising from external or internal causes, or from both combined.

The case of Nicolai, the celebrated bookseller of Berlin, affords a curious illustration of the long continuance of vivid spectral illusions, without the slightest belief of the real existence of the apparitions. "In a state of mind completely sound, and after the first terror was over, with perfect calmness," says this remarkable man, "I saw, for nearly two months, almost constantly and involuntarily, a vast number of human and other forms, and even heard their voices.

"My wife and another person came into my apartment in the morning, in order to console me, but I was too much agitated by a series of incidents, which had most powerfully affected my moral feeling, to be capable of attending to them. On a sudden, I perceived, at about the distance of ten steps, a form like that of a deceased person. I pointed at it, asking my wife if she did not see it? It was but natural that she should not see anything. My question therefore alarmed her very much, and she immediately sent for a physician. The phantom continued about eight minutes. I grew at length more calm, and being extremely exhausted, fell into a restless sleep, which lasted about half an hour. The physician ascribed the apparition to a violent mental emotion, and hoped there would be no return; but the violent agitation of my mind had in some way disordered my nerves, and produced further consequences, which deserve a minute description.

"At four in the afternoon, the form which I had seen in the morning re-appeared. I was by myself when this happened, and being rather uneasy at the incident, went to my wife's apartment, but there likewise I was persecuted by the apparition, which however at intervals disappeared, and always presented itself in a standing posture. About six o'clock there appeared also several walking figures, which had no connection with the first. After the first day the form of the deceased person no more appeared, but its place was supplied with many other phantasms, sometimes representing acquaintances, but mostly strangers: those whom I knew were composed of living and deceased persons, but the number of the latter was comparatively small. I observed the persons with whom I daily conversed did not appear as phantasms—these representing chiefly persons who lived at some distance from me.

"These phantasms seemed equally clear and distinct at all times, and under all circumstances, both when I was by myself and when I was in company, and as well in the day as at night, and in my own house as well as abroad; they were however less frequent when I was in the house of a friend, and rarely appeared to me in the street. When I shut my eyes, these phantasms would sometimes vanish entirely, though there were instances when I beheld them with my eyes closed; yet, when they disappeared on such occasions they generally returned when I opened my eyes. I conversed sometimes with my physician and my wife of the phantasms which at the moment surrounded me. They appeared more frequently walking than at rest, nor were they constantly present. They frequently did not come for some time, but always re-appeared for a longer or a shorter period, either singly or in company, the latter however being most frequently the case. I generally saw human forms of both sexes, but they usually seemed not to take the smallest notice of each other, moving as in a market-place, where all are eager to press through the crowd; at times however they seemed to be transacting business with each other. I also several times saw people on horseback, dogs, and birds. All these phantasms appeared to me in their natural size, and as distinct as if alive, exhibiting different shades of carnation in the uncovered parts, as well as different colours and fashions in their dresses, though the colours seemed somewhat paler than in real nature. None of the figures appeared particularly terrible, comical, or disgusting; most of them being of an indifferent shape, and some presenting a pleasing aspect.

"The longer these phantasms continued to visit me, the more frequently did they return; while at the same time they increased in numbers about four weeks after they had first appeared. I also began to hear them talk. These phantasms sometimes conversed among themselves, but more frequently addressed their discourse to me; their speeches were commonly short, and never of an unpleasant turn. At different times there appeared to me both dear and sensible friends of both sexes, whose addresses tended to appease my grief, which had not yet wholly subsided; their consolatory speeches were in general addressed to me when I was alone. Sometimes however I was accosted by these consoling friends while I was engaged in company, and not unfrequently while real persons were speaking to me."

Of the natural constitution of his mind, Nicolai states: "My imagination possesses in general *a great facility in picturing.* I have, for example, sketched in my mind a number of plans for novels and plays, though I have committed very few of them to paper, because I was less solicitous to execute than to invent. I have generally arranged these outlines when in a cheerful state of mind I have taken a solitary walk, or when travelling I have sat in my carriage, and could only find employment in myself and my imagination. Constantly, and even now, do the different persons whom I imagine in the foundation of such a plot *present themselves to me in the most lively and distinct manner, their figure, their features, their manner, their dress, and their complexion, are all visible* to my fancy. As long as I meditate on a fixed plan, and afterwards carry it into effect, even when I am interrupted and when I must begin it again at different times, all the acting persons *continue present in the very same form* in which my imagination at first produced them. I find myself frequently in a state between sleeping and waking, in which a number of pictures of every description, often of the strangest forms, show themselves, change, and vanish. In the year 1778 I was afflicted with a bilious fever, which at times, though seldom, became so high as to produce delirium. Every day, towards evening, the fever came on, and if I happened to shut my eyes at that time, I could perceive that the cold fit of the fever was beginning, even before the sensation of cold was observable. This I knew by the distinct appearance of coloured pictures, of less than half their natural size, which looked as in frames. They were a set of landscapes, composed of trees, rocks, and other objects. If I kept my eyes shut, every minute some alteration took place in the representation. Some figures vanished and others appeared. But if I opened my eyes, all was gone; if I shut them again, I had a different landscape. In the cold fit of the fever, I sometimes opened and shut my eyes every second, for the purpose of observation, and every time a different picture appeared, replete with various objects, which had not the least resemblance to those that appeared before. These pictures presented themselves without interruption, as long as the cold fit of the fever lasted. They became fainter as soon as I began to grow warm; and when I was perfectly so, all were gone. When the cold fit of the fever was entirely past, no more pictures appeared; but if on the next day I could again see pictures when my eyes were shut, it was a certain sign that the cold fit was coming on."

This is a remarkable instance of spectral illusion manifestly arising from a physical cause, in a person of a philosophical turn of mind, able to refer the illusions to their real source, and therefore to maintain his consciousness of their true nature. It was otherwise with John Beaumont, the author of a 'Treatise on Spirits and Apparitions,' who was a man of hypochondriacal disposition, and who, while labouring under this bodily disease, saw hundreds of imaginary men and women about him, and in whose real existence he came to be a firm believer. Among the spirits that visited him, there were two who became his constant attendants, and who called each other by their names: several spirits would often call at his chamber, and ask whether such spirits lived there, calling them by their names, and they would answer, they did. One spirit which came for several nights together, and rung a little bell in his ear, told him that his name was Ariel. The two spirits that constantly attended him were ladies of a brown complexion, about three feet in stature; they had both black loose net-work gowns, tied with a black sash about the middle; and within the net-work appeared a gown of a golden colour, with somewhat of a light striking through it. "These women told me they would kill me if I told any person in the house of their being there, which put me in some consternation, and I made a servant sit up with me four nights in my chamber, before a fire, it being in the Christmas holidays; telling no person of their being there. One of these spirits in woman's dress lay down upon the bed by me every night; and told me, if I slept, the spirits would kill me, which kept me waking for three nights. In the mean time, a near relation of mine went (though unknown to me) to a physician of my acquaintance, desiring him to prescribe me somewhat for sleeping, which he did, and a sleeping potion was brought me, but I set it by, being very desirous and inclined to sleep without it. The fourth night I could hardly forbear sleeping, but the spirit, lying on the bed by me, told me again I should be killed if I slept; whereupon I rose, and sat by the fire-side, and in a while returned to my bed; and so I did a third time, but was still threatened as before; whereupon I grew impatient, and asked the spirits what they would have?—told them I had done the part of a Christian, in humbling myself to God, and feared them not; and rose from my bed, took a cane, and knocked at the ceiling of my chamber; a near relation of mine lying then over me, who presently rose and came down to me, at two o'clock in the morning; to whom I said, you have seen me disturbed these four days past, and that I have not slept —the occasion of it was, that five spirits, which are now in the room with me, have threatened to kill me if I told any person of their being here, or if I slept; but I am not able to forbear sleeping longer, and acquaint you with it, and now stand in defiance of them: and thus I exerted myself about them; and, notwithstanding their continued threats, I slept very well the next night, and continued so to do, though they continued with me above three months, day and night."

We have seen that some minds, such as that of Nicolai, have a strong natural tendency to form vivid pictorial images of everything that interests them; in others, there is a like tendency to the intense renovation of past impressions. "I remember," says Dr. Ferriar, "that, about the age of fourteen, if ever I had been viewing any interesting object in the course of the day, such as a romantic ruin, a fine seat, or a review of a body of troops, as soon as evening came on, if I had occasion to go into a dark room, the whole scene was brought before my eyes, with a brilliancy equal to what it had possessed in daylight, and remained visible for several minutes. I have no doubt that dismal and frightful images have been often presented to the mind in the same manner after scenes of domestic affliction or public horror." Certain states of the body, and certain affections of the mind, powerfully predispose to the intense renovation of past impressions, however those impressions have been induced, and whatever their nature, the immediate exciting cause of the renovation being often some external object acting upon the senses or upon the imagination under circumstances favourable to the illusion. A large class of spectral illusions are referable to this head, of which the following may be taken as an example. A gentleman was benighted, while travelling alone, in a remote part of the highlands of Scotland, and was compelled to ask shelter for the evening at a small lonely hut. When he was to be conducted to his bed-room, the landlady observed, with mysterious reluctance, that he would find the window very insecure. On examination, part of the wall appeared to have been broken down to enlarge the opening. After some inquiry, he was told that a pedlar, who had lodged in the room a short time before, had committed suicide, and was found hanging behind the door in the morning. According to the superstition of the country, it was deemed improper to remove the body through the door of the house; and to convey it through the window was impossible, without removing part of the wall. Some hints were dropped that the room had been subsequently haunted by the poor man's spirit. My friend laid his arms, properly prepared against intrusion of any kind, by the bed-side, and retired to rest, not without some degree of apprehension. He was visited in a dream by a frightful apparition, and, awaking in agony, found himself sitting up in bed, with a pistol grasped in his right hand. On casting a fearful glance round the room, he discovered by the moonlight a corpse dressed in a shroud, reared erect against the wall close by the window. With much difficulty he summoned up resolution to approach the dismal object, the features of which, and the minutest parts of its funeral apparel, he perceived distinctly. He passed one hand over it, felt nothing, and staggered back to bed. After a long interval, and much reasoning with himself, he renewed his investigation, and at length discovered that the object of his terror was produced by the moonbeams, forming a long, bright image, through the broken window, on which his fancy, impressed by his dream, had pictured, with mischievous accuracy, the lineaments of a body prepared for interment. Powerful associations of terror, in this instance, had excited the recollected images with uncommon force and effect.

The peculiarity of constitution expressed by the term predisposition, whether corporeal or mental, is not only deeply implicated in the production of a general tendency to the formation of these phantoms, but it often determines even the specific character which each assumes. Since the predisposition varies in each individual, the same morbid cause may conjure up images the most diversified. The inhalation of nitrous oxide commonly excites vivid images of a pleasing nature, accompanied with grateful sensations; but in some cases it presents to the imagination frightful pictures, and produces on the system painful effects; and, for the same reason, the morbid cause, whatever it be, which gives rise to spectral illusions, may in one excite soothing and delightful visions, and in another hideous and appalling spectres. The daughter of Sir Charles Lee "saw, about two of the clock in the morning, the apparition of a little woman between her curtain and her pillow, who told her she was her (deceased) mother: that she was happy, and by twelve of the clock that day she should be with her. Whereupon she knocked up her maid, called for her clothes, and when she was dressed she went into her closet, and came not out again till nine, and then brought with her a letter, sealed, to her father; brought it to her aunt, the Lady Everard, told her what had happened, and desired, that as soon as she was dead it might be sent to him. She desired that the chaplain might be called to read prayers; and when prayers were ended, she took her guitar and psalm-book, and sat down upon a chair without arms and played and sang so melodiously and admirably, that her music-master, who was then there, admired at it. And near the stroke of twelve, she rose and sat herself down in a great chair with arms, and fetching a strong breathing or two, immediately expired." In this case, a spectral illusion occurring in a tender and susceptible frame, produced such a powerful impression upon the imagination, as absolutely to destroy life. The contrast to this is the case of the sturdy assessor to the Westminster Assembly, who received a visit from the arch-fiend himself, and whom he treated with a cool contempt, which must have astonished his Satanic majesty. "The devil, in a light night, stood by his bedside. The assessor looked awhile, whether he would say or do anything; and then said, 'If thou hast nothing to do, I have;' and so turned himself to sleep."

There are many cases on record which directly prove that there is often the closest possible connection between the very shape which these phantasms assume and the images which have previously occupied the mind. A writer in the 15th volume of Nicholson's 'Philosophical Journal,' who was haunted with the apparition of frightful spectres, and who was at length struck with some connection between these images and his previous thoughts, states, that he tried the experiment, whether, by fixing his meditation upon other objects, he could not make these assume the place of the phantasms which persecuted him; that with this view, while the faces were flashing before him, he reflected upon landscapes and scenes of architectural grandeur; that accordingly, after a considerable interval of time, a rural scene of hills, valleys, and fields appeared before him, which was succeeded by another and another, in ceaseless succession; that the manner and times of their respective appearance, duration, and vanishing, did not sensibly differ from those of the faces; that the scenes were calm and still, without any strong lights or glare; that, after a time, these figures changed entirely, and consisted of books, parchments, or papers, containing printed matter. The writer adds, "I was now so well aware of the connection of thought with these appearances, that, by fixing my mind on the consideration of manuscript instead of printed type, the papers appeared, after a time, only with manuscript writing, and afterwards, by the same process, instead of being erect, they were all inverted or appeared upside down. The intelligent and philosophical Nicolai saw nothing but men and women, in their natural form and aspect, horses, dogs, and birds: the illusions of superstitious minds consist of angels or devils, which assume all sorts of fantastic shapes. Remigius, who was a commissioner for the trial of witches in Lorrain, and who boasts that, in the course of fifteen years, he had condemned 900 criminals to the stake, paid particular attention to the form, features, and dress of demons; yet his statements clearly show that they did not vary from the gross sculptures and paintings of the middle ages, and that recollected images only were present to the persons labouring under the delusions for which they suffered death. They are said to be black faced, with sunk but fiery eyes; their mouths wide, and smelling of sulphur; their hands hairy, with claws; their feet horny and cloven. "A devil would appear like an angel, seated in a fiery chariot; or riding on an infernal dragon, and carrying in his right hand a viper; or assuming a lion's head, a goose's feet, and a horse's tail; or putting on a raven's head, and mounted on a strong wolf; with innumerable other fantastic shapes of a similar description. These mysterious and frightful images were not only made familiar to the imaginations of the people, but even to their very senses. They could go neither into their dwellings nor their temples without seeing them; they were sculptured on the walls of the church, they were carved on the wainscots of the domestic halls, and the air and the earth were peopled with them; there was not a hill nor a valley, not a wood nor a grove, not a fountain nor a stream, in which they were not seen and heard, and communed with. No place was void," says Burton, "but all full of spirits, devils, or other inhabitants; not so much as a hair breadth was empty in heaven, earth, or water above or under the earth." "Our mothers' maids," observes Reginald Scot, "have so terrified us with an ugly devil, having horns on his head, fier in his mouth, and a tail in his breach, eies like a bacon, fangs like a dog, claws like a beare, a skin like a niger, and a voice roaring like a lion, that we start and are afraid when we hear any one cry *baugh!*"

What wonder that these hideous phantoms should make an indelible impression on weak and ignorant minds, and exert an influence even over strong and cultivated understandings, which their better reason could not at all times resist! What wonder when, from corporeal disease, sensations and ideas were rendered preternaturally intense, or the vivacity of ideas was so increased as to overpower actual impressions, that these spectres should be seen in solitude, and heard in the storm; should dance before the eye, and whisper in the ear; should assume a menacing aspect in the dreams of the guilty, and come with the cherub's smile in the visions of the innocent; should be to the maniac all that existed, and to the feverish and dying what most they hoped or feared!

In regard to ghosts, it is observable that they were remarkably abundant in this country during the interregnum after the civil war in 1649. "The melancholic tendency of the rigid Puritans of that period; their occupancy of old family seats, formerly the residence of hospitality and good cheer, which in their hands became desolate and gloomy; and the dismal stories propagated by the discarded retainers to the ancient establishments, ecclesiastical and civil, contributed altogether to produce a natural horror unknown in other periods of our history." It is well known that ghosts commonly appear in the same dress they wore when living; sometimes, indeed, they are clothed all in white, but these are chiefly the "churchyard ghosts, who have no particular business, but seem to appear *pro bono publico*, or to scare drunken rustics from tumbling over their graves. Dragging chains is not the fashion of English ghosts, chains and black vestments being chiefly the accoutrements of foreign spectres, seen in arbitrary governments,—dead or alive English spirits are free." Ghosts are commonly pale, and often assume a misty or cloudy appearance, the spectral idea of colour not quite equalling in intensity the vividness of an immediate sensation. The phantoms seen by Nicolai were always of a paler colour than real beings; and when they began to diminish and disappear, their colour became fainter and fainter, until at last they appeared entirely white.

We cannot dismiss the subject of apparitions without observing, that the manner in which these phantoms have vanished before the light of knowledge affords a striking illustration of the blessings which descend even to the lowest of the people from the diffusion of the sound principles of philosophy. The powerful and capricious spirits which filled "the heavens, the earth, and the waters above and under the earth," added, in no inconsiderable measure, to the sum of human suffering. They were, in general, hideous in form, and malignant in intention; the number of the good small, that of the evil countless; and though of "soft and uncompounded essence," they might have come in what shape they chose, "dilated or condensed, bright or obscure," yet they did assume "forms forbidden," such as "retire to chaos, and with night commix;" and their visitations were much more often accompanied with "blasts from hell" than "airs from heaven." They produced powerful emotion, for the most part painful and of pernicious tendency. They afforded materials for the fiction of the poet, and the pencil of the painter; but the imagery of the one and the figures of the other were distinguished for incongruity and deformity, not for beauty and grace. Haunting the couch of sickness, in minds debilitated by disease, they often chased reason from its throne, and sometimes deprived the sufferer of life. The ignorant they terrified with false fears, and they afforded no compensation in the uniformity and efficacy with which they visited the guilty with remorse. As agents in the administration of reward and punishment they were most unjust. If they brought down vengeance on the criminal, it was not for the commission of crime, but the neglect of punctilios; and if, as guardian angels, they hovered about the pillow of the dying, they were not messengers of evil to the wicked, and ministers of grace to the good; but this "blessed troop, with faces bright like the sun, bearing garlands, and promising eternal happiness," was as disposed to waft to heaven the soul of the sinner as of the saint. By preoccupying the mind, they took off the attention from the observation of nature, and deprived it both of the power and of the disposition to discover the true solution of those physical, mental, and moral phenomena which could not wholly escape notice, and in this lies the real malignity of their influence. They incapacitated the mind for the perception of truth, disposed it for the reception of the grossest delusions of credulity, and prepared it for the admission of the most fallacious account of the sources of calamity and suffering. In the hands of the priest and the tyrant, they were potent to delude and enslave; and they did their work faithfully. The human mind will anticipate the future, and must reflect upon the past. In the former, there will always be sufficient to fear, and in the latter enough to regret, without the stimulus of fictitious terror, or the imputation of imaginary guilt. As long as the human frame can suffer, and is subject to death, the mind will require whatever light philosophy can pour upon it to preserve it from error, and whatever consolation religion can afford, to save it, at least, from misery, if not from despair. In philosophy, there is light, and in religion, consolation; and he is a friend to man who labours to secure to him these inestimable blessings, free from the admixture of ignorance and the alloy of superstition.

(*Westminster Review*, No. ii.; *An Essay towards a Theory of Apparitions*, by John Ferriar, M.D., 1813; *Sketches of the Philosophy of Apparitions, or an Attempt to trace such Illusions to their Physical Causes*, by Samuel Hibbert, M.D., 1824.)

APPARITOR, an officer employed in the ecclesiastical courts, "so called," says Burn, "from that principal branch in their office, which consisteth in summoning persons to appear;" as the canons direct that letters citatory are not to be sent by those who have obtained them, nor by their messenger, but the judge shall send them by his own faithful messenger. In 21 Hen. VIII. c. 5, as well as in the canons, apparitors are hence called summoners, or summers. The above Act restrains the number of apparitors kept by bishops, archdeacons, or their vicars or officials, or other inferior ordinaries.

Apparitor is a Roman word, and was used as a general term to signify any person who was in attendance on public functionaries (*iis apparebant*, whence the name) to execute their orders. The term accordingly includes a great variety of officers in the Roman system. Under the later Empire various magistrates and functionaries had their apparitors, whose duties and privileges are enumerated in the Justinian Code, 12, tit. 52, &c.

APPEAL (*appeller*, to accuse), in the old criminal law of England, was a vindictive action at the suit of the party injured by some heinous offence, in which the appellant, instead of merely seeking pecuniary compensation as in civil actions, demanded the punishment of the criminal.

It differed from an indictment in some material points. Being a proceeding instituted by a private person in respect of a wrong done to himself, the prerogative of the crown was not permitted to suspend the prosecution or to defeat it by a pardon. It seems to have been in reference to this peculiarity that the appeal is said to have been called by the celebrated Chief Justice Holt "a noble birthright of the subject," inasmuch as it was the only mode by which the subject could insist upon the rigorous execution of criminal justice without the risk of royal interposition on behalf of the offending party. Even a previous acquittal on an indictment for the same identical offence was no bar to the prosecution by the appellant; nor was a previous conviction a bar, where the execution of the sentence had been intercepted by a pardon. It was in the power of the appellant alone to relinquish the prosecution, either by releasing his right of appeal or by accepting a compromise.

Another remarkable feature of an appeal was the mode of trial, which in cases of treason or capital felony was either by jury or by battle, at the election of the defendant.

Where the latter form of trial was adopted, the following was the order of proceeding. The appellant formally charged the *appellee* with the offence: the latter distinctly denied his guilt, threw down his glove, and declared himself ready to prove his innocence by a personal combat. The challenge was accepted by the appellant, unless he had some matter to allege, in what was termed a *counterplea*, showing that the defendant was not entitled to the privilege of battle, and both parties were then put to their oaths, in which the guilt of the accused was solemnly asserted on one side and denied on the other. A day was then appointed by the court for the combat, the defendant was taken into custody, and the accuser was made to give security to appear at the time and place prefixed. On the day of battle, the parties met in the presence of the judges, armed with certain prescribed weapons, and each took a preliminary oath, of which the effect was that he had resorted to no unfair means for securing the assistance of the devil in the approaching contest. If the defendant was vanquished, sentence was passed upon him, and he was forthwith hanged. But if he was victorious, or was able to persist in the combat till starlight, or if the appellant voluntarily yielded, and cried *craven*, then the defendant was acquitted of the charge, and the appellant was not only compelled to pay damages to the accused, but was further subjected to very heavy civil penalties and disabilities.

Some of the details of this singular mode of trial, as reported by contemporary writers, are sufficiently ludicrous. Thus we are told that the combatants were allowed to be attended within the lists by counsel, and a surgeon with his ointments. In the reign of Charles I., Lord Rea, on a similar occasion, was indulged with a seat and wine for refreshment, and was further permitted to avail himself of such valuable auxiliaries as nails, hammers, files, scissors, bodkin, needle, and thread. (See Rushworth's 'Collections,' cited in Barrington's 'Observations,' p. 328.) We also learn from the 'Close Rolls' recently published, that parties under confinement preparatory to the trial were allowed to go out of custody for the purpose of practising or taking lessons in fencing. (See Mr. Hardy's 'Introduction,' p. 185.) The whimsical combat between Horner and Peter, in the 'Second Part of Henry VI.,' has made the proceedings on an appeal familiar to the readers of Shakspere; and the scene of a judicial duel upon a criminal accusation has been more recently presented to us in the beautiful fictions of Sir Walter Scott.

It appears probable that the trial by battle was introduced into our jurisprudence from Normandy. The 'Grand Coustumier' of that country, and the 'Assizes of Jerusalem,' furnish evidence of its early existence.

The courts of criminal jurisdiction in which it was admitted were the King's Bench, the Court of Chivalry, and (in the earlier periods of our legal history) the High Court of Parliament.

In some cases the appellant was able to deprive the accused of his choice of trial, and to submit the inquiry to a jury. Thus, if the appellant was a female; or under age; or above the age of sixty; or in holy orders; or was a peer of the realm; or was expressly privileged from the trial by battle by some charter of the king; or laboured under some material personal defect, as loss of sight or limb; in all such cases he or she was allowed to state in a counterplea the ground of exemption, and to refer the charge to the ordinary tribunal. The party accused was also disqualified from insisting on his wager of battle, where he had been detected in the very act of committing the offence, or under circumstances which precluded all question of his guilt. Indeed (if early authorities are to be trusted) it is far from clear that a criminal, apprehended *in flagranti delicto*, did not undergo the penalties of the law forthwith, without the formality of any trial at all. (See Palgrave's 'English Commonwealth,' vol. i. p. 210.) The law on this latter point formed the subject of an interesting discussion in the Court of King's Bench in the year 1818, in the case of *Ashford* v. *Thornton*, reported 1 Barn. & Ald. 405. Upon that occasion the defendant had been acquitted upon a prior indictment for the murder of a female, whom he was supposed to have previously violated. The acquittal of the accused upon evidence which appeared to many sufficient to establish his guilt occasioned great dissatisfaction, and the brother and next heir of the deceased was accordingly advised to bring the matter again under the consideration of a jury by the disused process of an appeal. The defendant waged his battle in the manner above described, and the appellant replied circumstances of such strong and pregnant suspicion as (it was contended) precluded the defendant from asserting his innocence by battle. It was, however, decided by the court that an appeal, being in its origin and nature a hostile challenge, gave to the appellee a right to insist upon fighting, and that the appellant could not deprive him of that right by a mere allegation of suspicious circumstances. The case would have proceeded in due course, if the legal antiquaries had not been disappointed of the rare spectacle of a judicial duel by the voluntary abandonment of the prosecution. In the following year an Act (59 Geo. III. ch. 46) was passed to abolish all criminal appeals and trial by battle in all cases both civil and criminal. ('Blackst. Comm.,' Mr. Kerr's ed., vol. iv. p. 376.)

The cases in which, by the ancient law, appeals were permitted, were treason, capital felony, mayhem, and larceny. Indeed, the earliest records of our law contain proofs that appeals were a common mode of proceeding in many ordinary breaches of the peace, which at this day are the subject of an action of trespass. The wife could prosecute an appeal for the murder of her husband; the heir male general for the murder of his ancestor; and in any case the prosecutor might lawfully compromise the suit by accepting a pecuniary satisfaction from the accused. Hence it was that the proceeding was in fact frequently resorted to for the purpose of obtaining such compensation, rather than for the ostensible object of ensuring the execution of justice on the offender. (See further, Hawkins's 'Pleas of the Crown,' book ii. chaps. 23 and 45; Kendal's 'Argument for Construing largely,' &c.; *Bigby* v. *Kennedy*, Sir Will. Blackstone's 'Reports,' p. 714; and the ingenious speculations of Sir F. Palgrave on the origin of trial by battle, in his work on the Commonwealth of England.)

Besides the appeal by innocent or injured parties, a similar proceeding was in certain cases instituted at the suit of an accomplice. The circumstances under which this might be done will be found under the article APPROVER.

APPEAL. The removal of a cause from an inferior court or judge to a superior one, for the purpose of examining the validity of the judgment given by such inferior court or judge, is called an appeal.

An appeal from the decision of a court of common law is usually prosecuted by *bringing error*, as it is termed, by means of which the judgment of the court below undergoes discussion, and is either affirmed or reversed in the court of error. [ERROR.]

The term appeal, used in the above sense, is by the law of England applied in strictness chiefly to certain proceedings in Parliament, in the privy council, in the courts of equity, in the Admiralty and ecclesiastical courts, and in the court of quarter sessions.

Thus, an appeal lies to the House of Lords from the decree of the Court of Chancery in this country, and in Ireland; and from the decision of the court of session in Scotland.

An appeal lies to the queen in council from the decrees and decisions of the colonial courts, and indeed from all judicatures within the dominions of the crown, except Great Britain and Ireland. [JUDICIAL COMMITTEE.] To the same jurisdiction are referred (in the last resort) all ecclesiastical and admiralty causes, and all matters of lunacy and idiotcy.

A decision of the Master of the Rolls or any of the Vice-Chancellors may be reversed or altered by the Lord Chancellor, or by the Lords Justices of the Court of Appeal in Chancery, upon a proceeding in the nature of an appeal.

An appeal lies directly from the vice-admiralty courts of the colonies, and from other inferior admiralty courts, as well as from the High Court of Admiralty, to the queen in council.

In the ecclesiastical courts, a series of appeals is provided from the Archdeacon's Court to that of the bishop, and from the bishop to the archbishop. From the archbishop the appeal lay to the pope until the reign of Henry VIII., when the supremacy being transferred to the crown, the appeal was thenceforth to certain delegates named by the sovereign. The court of delegates, appointed for each cause, to whom the sovereign *delegated* his authority, was the ordinary appellate tribunal, until the transference of their jurisdiction to the crown in council, by the statute 2 & 3 Will. IV. c. 92.

Such are the principal heads of appeal, to which we may add the appellate jurisdiction of the justices of the peace assembled at the quarter sessions, to whom various statutes have given authority to hear, upon appeal, the complaints of persons alleging themselves to be aggrieved by the orders or acts of individual magistrates.

In some cases an appeal in lieu of error is allowed from the superior courts of common law to the Exchequer Chamber, and thence to the House of Lords.

APPEARANCE. [PLEADING.]

APPLE. This fruit, which, from its hardiness and great abundance, combined with its excellent flavour, is one of the most important productions of cold climates, is, in its wild state, the austere crab-apple of the hedges. At what period it first began to acquire from cultivation the sweetness and other qualities which are peculiar to it in its domesticated state, or by what accident the tendency to amelioration was first given it, we have no means of ascertaining. All that we know is, that the apple is spoken of by Homer as being one of the fruit trees cultivated in the gardens of Alcinous and of Laertes, that it was a favourite fruit of the Romans, who had many varieties, and that it has never ceased to be an object of great interest with all northern nations.

It is a most inexplicable circumstance, that while some kinds of plants will produce a great multitude of varieties when raised from seed, and are susceptible of an almost unlimited degree of improvement, there are others of very nearly a similar nature which seem almost incapable of varying at all: and yet there are so many instances of it that the fact will not admit of doubt. Among these instances are the apple and the hawthorn: millions of millions of the latter have been raised in this country alone, and yet our gardens do not contain above half-a-dozen well-marked varieties; of the apple, on the contrary, which is, botanically, closely allied to the hawthorn, the varieties are innumerable; in the last edition of the 'Catalogue of the Garden of the Horticultural Society,' 1,400 are described; and it is probable that this is not more than half the number really known.

In the beginning, varieties, it may be supposed, were produced accidentally, owing to the peculiar tendency to change that this species of fruit possesses. A few varieties once obtained and placed in a garden, their blossoms would be certain to fertilise each other mutually, giving and taking the peculiar properties of one another: if the seeds of these were again sown, a greater degree of variation would arise; and this being repeated from generation to generation, the progeny would soon begin to differ so much from the original parents as scarcely to be recognisable. Until within comparatively a few years, varieties were procured in no other way than in this, and by constantly destroying inferior kinds as better were obtained; but since the discovery of the effect produced by fertilising one variety with another, a very rapid advance has taken place towards bringing the apple to its highest state of perfection, and the cultivator has no longer to trust to mere chance for the results of his experiments.

In procuring improved varieties of the apple, no other mode which leads to certain results has been discovered, than this of cross-fertilisation: but, at the same time, it is believed that the following circumstances ought to be kept in view: 1st, the seed from which the new variety is to be obtained should be fully formed, and 2nd, it should be taken from as perfect a specimen as it may be practicable to procure; for it has been found by experience, that any debility or defect in the parent is, in fruit trees, very apt to be communicated to their offspring. No person has been more successful in experiments of this kind than Mr. Knight, the President of the Horticultural Society, who thus describes his method of proceeding. "Many varieties of the apple were collected, which had been proved to afford, in mixture with each other, the finest ciders; a tree of each was then obtained by grafting upon a paradise stock, and these trees were trained to a south wall, or if grafted on a Siberian crab, to a west wall, till they afforded blossoms, and the soil in which they were planted was made of the most rich and favourable kind. Each blossom of this species of fruit contains about twenty chives, or males, and generally five pointals or females, which spring from the centre of the cup or cavity of the blossom. The males stand in a circle just within the bases of the petals, or flower leaves, and are formed of slender threads, each of which terminates in a small yellow ball or anther. It is necessary, in these experiments, that both the fruit and seed should attain as large a size, and as much perfection, as possible; and, therefore, a few blossoms only were suffered to remain upon each tree from which it was intended to obtain seeds. As soon as the blossoms were nearly full grown, every male in each was carefully extracted, proper care being taken not to injure the pointals or females: and the blossoms, thus prepared, were closed again, and suffered to remain till they opened spontaneously. The blossoms of the tree which it was proposed to make the male parent of the future variety were accelerated by being brought into contact with the wall, or retarded by being detached from it, so that those were made to unfold at the required period; and a portion of their pollen or farina, when ready to fall from the mature anthers, was, during three or four successive mornings, deposited upon the pointals of the blossoms, which consequently afforded seeds. It is necessary in this experiment that one variety of apple only should bear unmutilated blossoms; for where other varieties are in flower at the same time, the pollen of these will often be conveyed by bees to the prepared blossoms, and the result of the experiment will in consequence be uncertain and unsatisfactory."

"Every seed, though many be taken from a single apple, will afford a new and distinct variety, which will generally be found to bear some resemblance to each of its parents. Examples of this are presented in the Grange apple and Downton pippin, and in the Foxley apple and Siberian Harvey."

Of all the apples cultivated by our ancestors, a very small number only is known to the present generation. This may have been owing to their having gradually given way to better kinds; but, in the opinion of Mr. Knight, it is rather to be ascribed to an expenditure of their vital principle. This distinguished physiologist is of opinion, that no varieties of fruit trees are capable of remaining in perfection beyond a limited number of years: he thinks that after that period they suffer from the debility attendant upon old age, and that, although their existence may be protracted by means of grafting or budding them upon healthy stocks, yet that in the end they will entirely disappear. This opinion is founded upon the well-known fact, that the oldest varieties of the apple are now the most diseased, especially the celebrated golden pippin, which was formerly the common hardy cider-apple of the Herefordshire orchards, but which is now only preserved with difficulty in gardens. But it must be remembered, that however plausible this theory may be, it is open to several objections, among which more especially are the following: it is not impossible that the varieties alluded to by Mr. Knight were originally less hardy than those now cultivated, and that their constitutions were not adapted to the cold summers which generally prevail at the present epoch in England,—a supposition which is rendered the more probable by the circumstance, that the golden pippin still flourishes in all its pristine vigour in the island of Madeira. It may also be conjectured that neglect was a great cause of the disappearance of the golden pippin, and other kinds, from the cider orchards; for if, as is so often the case, the trees were once allowed to fall into a state of decay, then every scion taken from such trees for the purpose of propagation would carry its own debility along with it; and thus a disease, acquired in the first instance by neglect, would be perpetuated according to the well-known laws of vegetable physiology. (See Lindley's 'Outline of the First Principles of Horticulture,' p. 24, &c.)

It is not our intention in this place to enter into any detailed account of the varieties of the apple, for which we must refer our readers to works treating exclusively on such subjects, especially to the 'Guide to the Orchard and Kitchen Garden;' we shall rather confine ourselves to topics of general interest, such as the selection of varieties for small gardens or orchards, the modes of pruning and planting the trees, keeping the fruit when gathered, and propagation.

England is celebrated for the excellence of its cider; a beverage which perhaps acquires its highest degree of excellence in Herefordshire, and the neighbouring counties. In those districts, it has been found that the best varieties are the *foxwhelp*, a worn-out sort, much used for mixing with other kinds, to which it communicates strength and flavour; the *red must;* the *hagloe crab*, which, however, is only good in a dry soil, on a basis of calcareous stone, in a warm situation and season; the *grange apple;* the *orange pippin;* the *forest styre*, which is supposed to produce a stronger cyder than any other, but is not a good bearer; the *yellow Elliot;* the *Bennett;* the *Siberian Harvey; Stead's kernel;* the *friar*, which is very hardy; and above all, the *golden Harvey*, or *brandy apple*. The specific gravity of the juice of these varieties has been stated by Mr. Knight to be as follows:—

Foxwhelp	1076-1080	Yellow Elliot	1076
Red must	1064	Bennett	1073
Hagloe crab	1081	Siberian Harvey	1091
Grange	1079	Stead's kernel	1074
Orange pippin	1074	Friar	1073
Forest styre	1076-1081	Golden Harvey	1085

Besides these, the *coccagee* and the *Siberian bitter-sweet* are in much estimation.

For the kitchen, the apple is certainly, of all fruits, the most useful; and perhaps it is here that its utility to man is most conspicuous, because it proves, when cooked, a nutritious and wholesome food. In every district there is an abundance of local varieties, which are considered by their cultivators as of peculiar excellence. But for those who are anxious to possess the kinds which have been determined by comparison to be the best of all, we should recommend the following: for summer use, the *Keswick codlin* and the *Hawthornden;* for autumn, the *Wormsley pippin* and the *Alfriston;* for winter and spring, the *Bedfordshire foundling, Dumelow's seedling, Dr. Harvey, Brabant Bellefleur*, and *Gravenstein;* and for drying, the *Norfolk Beaufin*. Of all these, the Gravenstein, Alfriston, and Brabant Bellefleur are the best.

Of table apples, the varieties are endless; but by far the greater part of the local sorts, and of those commonly cultivated, is of only second-rate quality. The finest variety of all is the *Cornish gilliflower;* no other equals this in excellence, but it is unfortunately a bad bearer. Of those which combine productiveness and healthiness with the highest quality, the six following must be considered the best: *golden Harvey, old nonpareil, Hubbard's pearmain, Ribston pippin, Dutch mignonne, Court of Wick*. Finally, the best selection that could be made for a small garden, so as to obtain a constant succession of fruit from the earliest to the latest season, would be the following, which are enumerated in their order of ripening, the first being fit for use in June, and the last keeping till the end of April.

White Juneating.	Fearn's pippin.
Early Red Margaret.	Court of Wick.
White Astrachan.	Golden Harvey.
Sugar-loaf pippin.	Golden pippin.
Borovitsky.	Beachamwell.
Oslin.	Adam's pearmain.
Summer golden pippin.	Pennington's seedling.
Summer Thorle.	Hughes's golden pippin.
Duchess of Oldenburgh.	Cornish gilliflower.
Wormsley pippin.	Dutch mignonne.
Kerry pippin.	Reinette du Canada.
Yellow Ingestrie.	Skye-house russet.
Gravenstein.	Braddick's nonpareil.
Autumn pearmain.	Old nonpareil.
Golden reinette.	Court-pendu plat.
King of the pippins.	Lamb-Abbey pearmain.
Ribston pippin.	Newtown pippin.

In *pruning* the apple-tree, as indeed in all similar cases, three objects are chiefly kept in view; the first of which is to remove superfluous, or excessively vigorous shoots; the second is to admit light and air to all parts equally; and the third is to check exuberance, and thus to promote fruitfulness. The mode of proceeding in the two first cases is so obvious as not to require explanation; for the third, a few simple rules will suffice. As the apple is a tree of very hardy habits, if its branches are allowed to go unpruned, they will not produce any considerable number of lateral shoots, but will have a great tendency to keep lengthening from their terminal buds, which always produce barren and vigorous shoots; it is the lateral shoots only that are fertile, and they are so only when stunted, or in the state of what are technically called *spurs*. The mode of procedure is then obviously to destroy the terminal barren shoots, and to encourage the lateral fertile ones. This is effected by shortening back all the leading shoots every year, to a distance from their point of origin, which varies according to their strength: where they are very strong, the leading shoots should not be reduced more than within twelve or fifteen inches of their base, but when they are weaker, they may be cut to within nine inches. By this means the onward growth of the branch is momentarily arrested; the ascending sap is impelled into the lateral buds, which are thus developed, and form branches, some of which will be sure to grow so slowly as to become productive; for notwithstanding the check the branch may receive from the amputation, it will after a little while again lengthen by means of the bud nearest its extremity, and this latter will then grow so fast as effectually to hinder the new lateral shoots from acquiring much vigour. Of the lateral shoots then obtained, some will be required to form new branches, others will be preserved for fruiting, and others will at once become fruit spurs; the first will be treated as those from which they sprang, the second are to be cut down to within an inch of the bottom, which will generally cause the surrounding eyes to form fruit spurs; the third will be left until they have borne fruit, when they are cut out so as to leave only a single bud behind. In all cases, the fruit spurs, which, like the leading branches, have a tendency to lengthen, should have that tendency stopped by being cut back to the length of about three inches.

Apple-trees are *trained* in the form either of *standards, dwarfs, espaliers*, or *balloons*.

No particular care is requisite in the management of *standards* beyond providing them with a straight stem six feet high, and a head consisting of three or four healthy shoots to commence with; and afterwards keeping the branches so pruned that they do not chafe against each other in windy weather, nor overshadow each other; all the rest is generally provided for sufficiently by nature herself. They are principally employed in planting orchards, being now seldom admitted into good gardens. As these orchards are of inestimable value to the farmer and the peasant, the best mode of planting them cannot be too generally understood: we therefore select, from many others, the following method recommended by Mr. Knight. "Let a soil of good quality be selected for a nursery, which should be trenched eighteen inches deep, and planted with seedling crab stocks of one year old, each plant being placed at the distance of six feet from the others. These will be fit for grafting at two years old; and an acre of ground, thus planted, will contain about 1500 trees, and, consequently, enough to plant about forty acres, where each tree stands at twelve yards distance from others. A nursery thus planted, when the trees are seven or eight years old from the seed, will form a more productive orchard than can be obtained by any other means with which I am acquainted; and during the earlier periods of the growth of the trees, they will be rather benefited than injured if the ground be planted with potatoes, or other low-growing crops, with proper manure. During the growth of the trees in the nursery, they should not be pruned to single stems, without leaves, as is usually done in nurseries, but each should retain many small lateral branches, which will tend to make the young trees grow strong and taper in their stems, and will afford much fruit whilst the trees are very young. I would recommend the Downton pippin for an experiment of this kind, in preference to any other variety.

"At the end of eight or nine years from the time when the trees are first planted, they will have covered with their branches the whole surface of the ground, and will then begin to injure each other, if the whole be suffered to remain. At this period, therefore, every other row of trees, and at no distant subsequent period, every other tree in the remaining rows, must be taken away; and if this be done with proper care, and leaving the roots at least two feet long upon each side of the trunks, such trees may be removed with still less risk than such as are much smaller. But to insure success, it will be necessary to take off much the greater part of the lateral branches; and the holes in which the trees are to be planted must be made not less than six feet wide, and eighteen inches deep, placing the turf, if the field be pasture, in the bottom, and taking care that the trees be not planted deeper in the soil than they previously grew. Each tree will require, during the first year, a stake and a few bushes to protect it; after which, nothing more will be wanting than to wash its trunk annually with lime and water, and cow dung, to defend it from the teeth of sheep and cattle."

For garden purposes, *dwarf* apple trees are so far superior to all others, that they are now almost exclusively planted. Independently of the little space they occupy, the small degree in which they overshadow the soil, and the great facility they offer for gathering their fruit, they are generally so much beyond the influence of high winds as to have but little of their crop blown down by autumnal gales, and their fruit is also finer than on standards. No directions for their management can be given better than the following excellent observations of the author of the 'Guide to the Orchard and Fruit Garden.'

"Trees for this purpose should have their branches of an equal strength: those which have been grafted one year, or what are termed by nurserymen Maiden plants, are the best; they should not be cut down when planted, but should stand a year, and then be headed down to the length of four or six inches, according to their strength; these will produce three or four shoots from each cut-down branch, which will be sufficient to form a head. At the end of the second year, two or three of the best placed of these from each branch should be selected, and shortened back to nine, twelve, or fifteen inches each, according to their strength, taking care to keep the head perfectly balanced (if the expression may be allowed), so that one side shall not be higher nor more numerous in its branches than the other; and all must be kept, as near as may be, at an equal distance from each other. If this regularity in forming the head be attended to and effected at first, there will be no difficulty in keeping it so afterwards, by observing either to prune to that bud immediately on the inside, next to the centre of the tree, or that immediately on the outside. By this means, viewing it from the centre, the branches will be produced in a perpendicular line from the eye; whereas, if pruned to a bud on the right or left side of the branch, the young shoot will be produced in the same direction; so that if the branches formed round a circle be not thus pruned to the eyes, on the right successively, or the left successively, a very material difference will be found, and the regularity of the tree will be destroyed in one single year's pruning; which may be readily illustrated thus:—fix four branches, either in a direct line or to a circular hoop, at the distance of eight inches from each other; let the branch on the left be called *a*, the second *b*, the third *c*, the fourth *d*; head down *a* to the left-hand bud; *b* to the right, *c* to the left, and *d* to the right. When these have grown a year, those between *a* and *b*, and between *c* and *d*, will be ten inches: thus the distances now are not as eight to eight, but as six to ten; which would require two years pruning in a contrary direction to restore the head to its former regularity; and it must not be forgotten that this system of pruning will hold good in every other case.

"What has just been said has reference only to the leading shoots, which are always produced from the terminal buds when pruned, and which alone form the figure and beauty of the tree. The intermediate space must of course be provided for at the same time, having a regard to the number of branches thus employed, that they do not crowd each other. On the contrary, they must be kept thin, and perfectly open, so as to admit plenty of sun and air, without which the fruit produced will be small and good for but little: the middle of the tree, indeed, must be kept quite open from the first to the last, taking care that all the surrounding branches lead outwards, and preserve a regular distance from each other.

"*Espalier* apple-trees were formerly much used, but they are in all respects so greatly inferior to dwarfs, and so much more expensive to keep in good order, that we omit all further notice of them.

"A mode of managing apple-trees called *Balloon* training has been much recommended. It consists simply in this: you plant a common standard tree, with a stem six or seven feet high, and with five or six good equal-sized branches; to the tip of each branch is to be attached a cord which passes under a peg driven into the ground near the stem, and by means of which the branches may be gradually drawn downwards so as to become inverted, when, from the breadth of the part of the tree whence the branches diverge, and the approximation of their points, the whole assumes the appearance of a balloon. All the care that these trees require is, to have their branches kept at equal distances by means of a hoop, or some such contrivance, until they are strong enough to preserve their acquired direction, and to have all the shoots which will every year spring upwards from them carefully cut away, except such as can be brought down so as to fill up the spaces in the circumference of the balloon head. Trees thus managed produce an abundance of spurs, and when loaded with fruit are beautiful objects; like dwarfs, they occupy but little room, and their crop is not liable to be blown down; but they have this very great disadvantage, that all their buds are exposed to the sky in the spring, when they flower; consequently they are liable to suffer very much from the effect of spring frosts; so that they will scarcely ever bear, except in very favourable seasons, or in very mild and sheltered places. It is, in fact, only into gardens sloping to the south or south-west, and on the sides of valleys, that balloon apple-trees should be admitted.

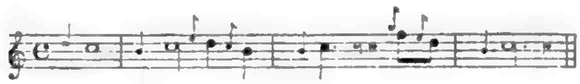
"Many different methods of *preserving* apples have been recommended, and almost every one has some favourite plan of his own. As far as our own experience goes, the best mode is to allow the fruits, after being gathered, to lie till their superfluous moisture has evaporated, which is what is technically called *sweating*; the apples should then be wiped quite dry, wrapped in tissue paper, and stowed away in jars or chests of pure silver sand which has been previously dried in an oven. They should always be taken out of the sand a few days before they are wanted, and laid in dry fern or some such substance; they then absorb oxygen, and acquire a little sweetness, which is necessary to their perfection."

The apple is *propagated* by either budding or grafting; the former practice is preferable for standards, the latter for dwarfs. The stocks that are employed are the wild crab, the doucin or English paradise, and the French paradise apple. The former should be used for standards only, as it imparts too much vigour to the scions to render them manageable as dwarfs; the French paradise should always be employed for the latter, as it has the property of stunting the shoots, and rendering them much more fertile. The doucin or English paradise stock, which is what the English nurserymen usually sell as *the* paradise stock, is intermediate in its effect between the crab and the French paradise, being less vigorous than the first and more so than the last. When there is no wish to confine the dwarf trees within a very narrow compass, this kind of stock, which is hardier than the French paradise, is the proper one to employ; but if the dwarfest trees that can be procured are the objects of the cultivator, then the latter only should be planted.

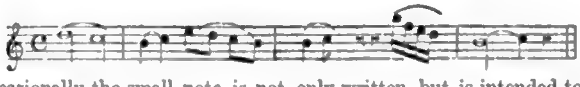
In conclusion, it is only necessary to add, that the proper season for planting the apple is in October or November, as soon as the leaves are dead or discoloured, and beginning to drop. Vegetation at that season is not altogether torpid, but goes on just enough to enable the plants to send out a few rootlets before winter, and to prepare themselves for taking advantage of the first period of growth in the succeeding spring—a period, the commencement of which is never exactly known by external indications.

APPOGIATURA (in Music), is a note of expression or embellishment, written in a smaller character than the essential notes of the melody. It is used for the purposes of emphasis, especially in recitative. The appogiatura takes its length or duration from the note it precedes, whence it usually abstracts half (except in the case of a dotted or pointed note, from which it takes two-thirds). In the following example, many varieties of the appogiatura are introduced:

As written.



As performed.



Occasionally the small note is not only written, but is intended to be performed, as a very short one. The appogiatura gives tenderness to the air, and is therefore not adapted to music of an energetic or majestic kind. In the hands of an accomplished performer, it is perhaps the most expressive and impassioned addition entrusted to his discretion; but, like other niceties, it fails in inferior hands.

APPORTIONMENT. Apportionment of rent, &c. is a term of law, signifying the dividing of a rent, annuity, or other payment recurring at fixed periods, and may be either among several persons entitled to the rent, or between the person entitled to the rent and the person or persons liable to the payment of it.

A rent issuing out of land may be apportioned in two ways; one by granting the reversion of part of the land out of which the rent issues, the other by granting part of the rent to one person and part to another. When rent is reserved upon a lease, and the lessor disposes of part of the lands in reversion, either by will or deed, the rent is apportionable, provided the lessee concur. But the lessee is not bound by any apportionment made without his consent. If the lessor or a stranger recovers any part of the land, or the lessor enters for a forfeiture upon part thereof, or the lessee surrenders a part to the lessor, the rent will be apportioned in respect to the part so recovered or surrendered and the part remaining in the hands of the lessee.

When a lessee aliens a part of the land comprised in his lease, the alienee is liable in an action of covenant for a proportional part of the rent reserved on the lease, the covenant for payment of rent being one which runs with the land; and therefore as respects him there is an apportionment of the rent. The alienation of a part of the lands does not however, any more than an assignment of the whole, discharge the original lessee from his liability upon his express personal covenant for payment of the whole rent. The right of distress for the whole rent upon every part of the land of course remains unaffected by the assignment, unless, as is sometimes done in the case of building leases, the original grantor agrees to restrict his right of distress on the lands aliened to a proportionate part of the rent.

If a man having a rent-charge issuing out of lands purchases any part of them, the rent-charge is extinct as to the whole; but if part of the land out of which the rent issues descends upon the owner of the rent-charge, the rent will be apportioned. And this will also be the case upon a partition of the lands out of which the rent issues. If a grantee of a rent-charge release all his right in part of the land charged, he extinguishes the whole rent; but if a grantee of a rent-charge release part of the rent to the grantor, the residue will remain charged on the land, for here the grantee deals with the rent only, not with the land. On the principles here stated a difficulty arises on the sale of part of lands subject to a rent-charge. Where the party entitled to the rent is willing to release the land to be sold, the mode sometimes adopted is for the owner of the rent-charge to assign it to a trustee upon trust to receive it exclusively out of the lands intended to remain charged. Another mode is for the annuitant to join in the conveyance of the lands sold, and to add a proviso that the other lands shall continue liable. This plan, however, is open to the objection that as the proviso operates as a new grant, the rent-charge becomes liable to the incumbrances of the owner of the land created before the conveyance. A third mode, sometimes adopted, is that of the owner of the rent-charge covenanting not to distrain on the lands sold, but it seems doubtful whether such a covenant does not operate as a release of the rent-charge. If the owner of the rent-charge will not concur, the only plan seems to be for the vendor to covenant with the purchaser that the lands not sold shall be exclusively liable, and give an indemnity by demise or otherwise against the rent-charge. It seems that the technical rule of law which is productive of so much inconvenience ought to be altered.

By the common law, if a lessor tenant for life died within the half-year at the end of which rent was due upon a lease not made in execution of a power, and which therefore determined on the death of the tenant for life, the half year's rent could not be apportioned, and was therefore lost both to the representatives of the lessor and to the remainder-man or reversioner, upon whom the lease was not binding.

To remedy this evil it was provided by the stat. 11 Geo. II. c. 19, § 15, that where a lessor tenant for life died before the rent-day, his executors might recover from the tenant a proportionate part of the rent then growing due, making all just allowances. But as this statute was construed to apply only to persons strictly tenants for life, and had no application to the case of a lease made by a tenant in fee or by a tenant in tail under a power, if in either of these cases the lessor died in the interval between two periods of the rent being due, the whole rent went, according to the rule of the common law, to the heir or remainder-man, and there could be no apportionment in favour of the executor. The law has now been altered by the stat. 4 & 5 Wm. IV. c. 22, the object of which is to apply the principle of equitable apportionment to all property which consists in periodical and fixed money payments.

By the first section it is declared that rents reserved on leases determining on the death of the person making them (though not strictly tenant for life), or on the death of the tenant *pur autre vie*, shall be considered as within the provisions of the above-mentioned stat. 11 Geo. II. c. 19, § 15.

By the 2nd section it is enacted that from the passing of the act all rents service reserved on any lease by a tenant in fee, or for any life interest, or by any lease granted under any power (and which leases shall have been granted after the passing of the act), and all rents-charge and other rents, annuities, pensions, dividends, moduses, compositions, and all other payments of every description in the United Kingdom of Great Britain and Ireland made payable or coming due at fixed periods under any instrument that shall be executed after the passing of the act (or being a will or testamentary instrument) that shall come into operation after the passing of the act, shall be apportioned so and in such manner that on the death of any person interested in any such rents, annuities, pensions, dividends, moduses, compositions, or other payments, as aforesaid, or in the estate, fund, office, or benefice from or in respect of which the same shall be issuing or derived, or on the determination by any other means whatsoever of the interest of any such person, he or she, and his or her executors, administrators, or assigns, shall be entitled to a proportion of such rents, annuities, pensions, dividends, moduses, compositions, and other payments, according to the time which shall have elapsed from the commencement or last period of payment thereof respectively (as the case may be), including the day of the death of such person or of the determination of his or her interest, all just allowances and deductions in respect of charges on such rents, annuities, pensions, dividends, moduses, compositions, and other payments being made; and that every such person, his or her executors, administrators, or assigns, should have such and the same remedies at law and in equity for recovering such apportioned parts of the said rents, annuities, pensions, dividends, moduses, compositions, and other payments, when the entire portions of which such apportioned parts shall form part shall become due and payable, and not before, as he, she, or they would have had for recovering and obtaining such entire rents, annuities, pensions, dividends, moduses, compositions, and other payments if entitled thereto, but so that persons liable to pay rents reserved by any lease or demise, and the lands, tenements, and hereditaments comprised therein shall not be resorted to for such apportioned parts specifically as aforesaid, but the entire rents of which such portions shall form a part shall be received and recovered by the person or persons who, if the act had not passed, would have been entitled to such entire rents; and such portions shall be recoverable from such person or persons by the parties entitled to the same under the act in any action or suit at law or in equity. It seems doubtful whether the above enactment will apply to the case of an annuity payable at certain periods and determinable at the death of the grantor, because if the annuity cease by the death of the grantor on any day before that of payment, the 'entire portion' can never become payable. It is advisable therefore to retain the usual apportionment clause in the grants of such annuities.

The 3rd and last section provides that the act is not to apply to cases in which it shall be expressly stipulated that no apportionment shall take place, nor to annual sums made payable on policies of assurance of any description.

Rights of common are apportionable in certain cases. Common of pasture where it is appendant may be apportioned either where the commoner purchases a part of the land in which he has the right of common, or upon an alienation of part of the land to which the right is appendant. In the case of common of pasture appurtenant, there will be apportionment in the second case, but not in the first. Common of estovers or piscary cannot be apportioned, neither can the rights of horsebote, haybote, &c. be appendant to the freehold.

Conditions in general cannot be apportioned by the act of the parties, though they may where a division of the estate is caused by the act of law or by the act and wrong of a lessee upon condition.

(Upon the subject of Apportionment see Cruise, *Dig.* vol ii. 36, vol. iii. 72, 302 *et seq.*)

APPRAISEMENT, from *apprécier*, *appriser*, or *appraiser*, "to set a price upon an article." When goods have been taken under a distress for rent, it is necessary, in order to enable the landlord to sell them according to the provisions of the statute 2 William and Mary, sess. i. c. 5, that they should be previously appraised or valued by two appraisers. These appraisers are sworn by the sheriff, under-sheriff, or constable, to appraise the goods truly according to the best of their understanding. After such an appraisement has been made, the landlord may proceed to sell the goods for the best price that can be procured. By the statute 48 Geo. III. c. 140, an *ad valorem* stamp duty is imposed upon appraisements.

APPRAISERS are persons employed to value property. By the statute 46 Geo. III. c. 43, it was first required that any person exercising the calling of an appraiser should annually take out a license to act as such, stating his name and place of abode, and signed by two commissioners of stamps. By the same statute a stamp duty of 6*s.* was imposed upon such licenses; and unlicensed persons were forbidden to act as appraisers under a penalty of 50*l.* The same duty was continued by the General Stamp Act, 48 Geo. III. c. 149, but by the 8 & 9 Vict. c. 76, the duty was raised to 2*l.*

APPRENTICE, from *apprendre*, to learn, signifies a person bound by indenture to serve a master for a certain term, receiving, in return for his services, instruction in his master's profession, art, or occupation. In addition to this, the master is usually bound to provide the necessary food and clothing for the apprentice, and sometimes to pay him small wages, but most commonly the master receives a premium. Formerly the word was used to denote those students of the common law in the societies of the inns of court who—not having completed their professional education by ten years' study in those societies, at which time they were qualified to leave their inns and to execute the full office of an advocate, upon being called by writ to take upon them the degree of serjeant-at-law—were yet of sufficient standing to be allowed to practise in all courts of law except the court of Common Pleas. This denomination of apprentice (in law Latin, *apprenticii ad legem nobiliores, apprenticii ad barras*, or simply *apprenticii ad legem*) appears to have continued until the close of the 16th century, after which this term fell into disuse, and we find the same class of advocates designated, from their pleading without the bar, as *outer* barristers, now shortened into the well-known term, barristers. (See Spelman's 'Gloss. ad verbum;' Blackstone's 'Commentaries,' vol. i. 23; vol. iii. 27.)

Apprenticeship appears to have been unknown to the ancients; and although it has been stated that in Rome the distribution of the citizens into companies or colleges according to their trades took place at an early period, we can discern in the Roman history no distinct traces of such a system as apprenticeship. Its origin is to be sought in the institutions of modern Europe, and it probably sprung up in conjunction with the system of associating handicraft trades in the 12th century, the natural result, perhaps, of those more general combinations of citizens or of burgesses, which were formed for the purposes of mutual protection against feudal oppression. The restraint of free competition, the assertion of peculiar privileges, and the limitation of the numbers of such as should participate in them, were the main results to which these institutions tended: and for these purposes a more obvious or effective instrument than apprenticeship could hardly be found. To exercise a trade, it was necessary to be free of the company or fraternity of that trade; and as the principal if not the only mode of acquiring this freedom in early times was by serving an apprenticeship to a member of the body, it became easy to limit the numbers admitted to this privilege, either indirectly by the length of apprenticeship required, or more immediately by limiting the number of apprentices to be taken by each master. So strict in some instances were these regulations, that no master was allowed to take as an apprentice any but his own son. In agriculture, apprenticeship, though in some comparatively later instances encouraged by positive laws, has never prevailed to any great extent, which is probably to be attributed to its origin as a part of the system of associated trades. The tendency to association, indeed, is not strong among the agricultural population, combination being, to the scattered inhabitants of the country, inconvenient and often impracticable; whereas the inhabitants of towns are, by their very position, invited to it.

Subsequently to the twelfth century, apprenticeship has prevailed in almost every part of Europe. In France, Germany, Italy, and Spain, it may be distinctly traced, and it probably existed in various other countries. It is asserted by Adam Smith, that seven years seems anciently to have been all over Europe the usual term established for the duration of apprenticeships in most trades. There seems, however, to have been no settled rule on this subject, for there is abundant evidence to show that the custom in this respect varied not only in different countries, but in different incorporated trades in the same town.

In Italy, the Latin term for the contract of apprenticeship was *acconventatio*. From an old form of an Italian instrument, given by Beier in his learned work, 'De Collegiis Opificum,' it appears that the contract, which in most respects closely resembled English indentures of apprenticeship, was signed by the father or other friend of the boy who was to be bound, and not by the boy himself, the latter testifying his consent to the agreement merely by being present.

In France, the trading associations prevailed to a great extent, under the names of "Corps de Marchands" and "Communautés." At the latter end of the 17th century, there were in Paris six "Corps de Marchands," and one hundred and twenty-nine "Communautés," or companies of tradesmen, each fraternity having their own rules and laws. Among these bodies the duration of apprenticeship varied from three to eight or ten years. It was an invariable rule in the "Corps de Marchands," which was generally followed in the "Communautés," that no master should have more than one apprentice at a time. There was also a regulation that no one could exercise his trade as a master until, in addition to his apprenticeship, he had served a certain number of years as a journeyman. During the latter term he was called the "compagnon" of his master, and the term itself was called his "compagnonage." He had also, before being admitted to practise his trade as master, to deliver to the "jurande," or wardens of the company, a specimen of his proficiency in his art, called his "chef-d'œuvre." He was then said "aspirer à la maîtrise." The sons of merchants living in their father's house till seventeen years of age, and following his trade, were reputed to have served their apprenticeship, and became entitled to the privileges incidental to it without being actually bound. These companies or associations were finally abolished at the revolution, when a perfect freedom of industry was recognised by the laws, and this, with a few exceptions, has continued to the present day. But though the contract of apprenticeship has ceased in France to be imperative upon the artisan, it has not fallen into disuse; and an Act passed the 12th of April, 1803, prescribes the rights and duties both of master and apprentice. It does not, however, lay down any particular form, and leaves the time and other conditions of the contract to be determined by the parties.

In Germany, though we find the same institution, it varies not only in the name, but has some other remarkable peculiarities. The companies there called *gilden*, *zünfte*, or *innungen*, appear to have exercised in many respects a sort of judicial control over their members, and, either on account of moral or physical defects, to have refused admission to applicants for freedom at the discretion of the elders or masters. They seem to have occasionally admitted workmen who had not served a regular apprenticeship into the lower class of members of a trade; but to become masters was only allowed to those who had gone through the regular stages of instruction. The course which continues to the present day is as follows:—The apprentice, after having served the term prescribed by his indenture (*aufdings-brief*), is admitted into the company as a companion (*gesell*), which corresponds in many respects to the French *compagnon*. Having passed through the years of his apprenticeship, called *lehr-jahre*, satisfactorily, he becomes entitled to receive from the masters and companions of the guild a certificate, or general letter of recommendation (*kundschaft*), which testifies that he has duly served his apprenticeship, and has been admitted a member of the company, and commends him to the good offices of the societies of the same craft, wherever he may apply for them. With this certificate the young artisan sets out on his travels, which often occupy several years, called *wandel-jahre*, supporting himself by working as a journeyman in his particular art or trade in the various towns in which he temporarily establishes himself, and availing himself of his *kundschaft* to procure admission into the fellowship and privileges of his brother workmen of the same craft. On his return home, he is entitled, upon producing certificates of his good conduct during his *wandel-jahre*, to become a master. In Germany, the periods of servitude have varied in different states and at different periods; in general, the term is seven years; but in some instances an apprenticeship of five or three years is sufficient.

Neither in Ireland nor in Scotland have the laws relating to associated trades or apprentices been very rigorously enforced. In the former, the same system of guilds and companies certainly existed; but, as it was the policy of the English government to encourage settlers there, little attention was paid to their exclusive privileges; and in 1672 the Lord Lieutenant and Council, under authority of an Act of Parliament, issued a set of rules and regulations for all the walled towns in Ireland, by which any foreigner was allowed to become free of the guilds and fraternities of tradesmen on payment of a fine of 20*s*. A statute containing very similar enactments was passed in 19 Geo. III. The term of apprenticeship, also, in Ireland, was of a moderate length, five years being required by 2 Anne, c. 4, for the linen manufacture, which, by 10 Geo. I., c. 2, was reduced to four years. It is asserted by Adam Smith, that there is no country in Europe in which corporation laws are so little oppressive as in Scotland. Three years are there a common term of apprenticeship even in the nicer trades, but there is no general law on the subject, the custom being different in different communities.

It is, perhaps, impossible to ascertain precisely at what time apprenticeships first came into general use in England. But that the institution is one of very old date is certain, being probably contemporaneous with the formation of the guilds or companies of tradesmen. In the statutes of the realm, however, there is no reference to such an institution for about 200 years after the guilds are known to have existed, apprentices being first incidentally noticed in an act (12 Rich. II. c. 3) passed in 1388. But that about this time apprenticeship had become extremely common is proved by a statute passed in 1405-6 (7 Hen. IV. c. 17), which contains the singular enactment, that no one shall bind his son or daughter apprentice unless he have land or rent to the value of 20*s*. by the year; the cause of which provision is stated to be the scarcity of labourers in husbandry, in consequence of the custom of binding children apprentices to trades. In the act (8 Hen. VI. c. 11) which repealed this statute in favour of the city of London, the putting and taking of apprentices is stated to have been at that time a custom of London time out of mind. The same statute was repealed (by the 11th Hen. VII. c. 11) in favour of the citizens of Norwich, and (by the 12th Hen. VII. c. 1) in favour of the worsted-makers of Norfolk; and in the former act we find the first mention of any particular term of servitude, the custom of the worsted-sheerers of Norwich being confirmed by it, which required an apprenticeship of seven years. Except in London, it does not appear that at an early period there was in England any uniform practice in this respect, but that the duration of the apprenticeship was a matter for agreement between the parties to the contract. In Madox's 'Formulare Anglicanum,' there is an indenture of apprenticeship dated in the reign of Henry IV., which is nearly in the same form as the modern instrument; and in that case the binding is to a carpenter for six years. It is, however, probable that before the statute of the 5th Eliz. c. 4, the term of apprenticeship was seldom less than seven years. In London, the period of seven years at the least was expressly prescribed by the custom as the shortest term; and Sir Thomas Smith, in his 'Commonwealth of England,' written about the time of the passing of the statute of Elizabeth, says, in reference to the previous practice, that the apprentice "serveth, some for seven or eight years, some nine or ten years, as the master and the friends of the young man shall think meet, or can agree together."

The statute of the 5 and 6 Edw. VI. c. 8, which enacts that no person shall weave broad woollen cloth, unless he have served a seven years' apprenticeship, may be adduced as a further proof that this term was fast becoming the customary one, when, by the 5th Eliz. c. 4, it was made the law of the land, and one uniform practice in all trades introduced throughout England. But neither by that statute, nor by the customs of London and Norwich, which were excepted by the act, was a longer term of apprenticeship than seven years forbidden.

The London apprentices, in early times, were an important, and often a formidable body. They derived consequence from their numbers, the superior birth of many of them, and the wealth of their masters, but particularly from their union, and the spirit of freemasonry which prevailed among them. The author of a curious poem published in 1647, entitled 'The Honour of London Apprentices,' observes, in his preface, that "from all shires and counties of the kingdom of England and dominion of Wales, the sonns of knights, esquiers, gentlemen, ministers, yeomen, and tradesmen, come up from their particular places of nativity and are bound to be prentices in London." He also mentions "the unanimous correspondence that is amongst that innumerable company."

It may be readily supposed that such a body, in the midst of a large metropolis, densely crowded with population, and frequented by strangers of all kinds, was not a little obnoxious to the police; and accordingly, we find in the 16th and 17th centuries a constant succession of tumults, and some instances of serious and alarming insurrections arising among the apprentices. Thus the fatal riot in London against foreign artificers, which took place on the 1st of May, 1517, and from which that day was called 'Evil May Day,' was commenced and encouraged by the apprentices.

In the year 1595, certain apprentices in London were imprisoned by the Star-Chamber for a riot; upon which, several of their fellows assembled and released them by breaking open the prisons. Many of these were taken and publicly whipped by order of the Lord Mayor. This caused a much more formidable disturbance; for 200 or 300 apprentices assembled in Tower-street, and marched with a drum in a warlike manner to take possession of the person of the Lord Mayor, and, upon the principle of retaliation, to whip him through the streets. Several of the ring-leaders in this riot were tried and convicted of high treason. (See 'Criminal Trials,' vol. i. p. 317.)

In the troubles of the civil wars the apprentices of London took an active part as a political body; numerous petitions were presented from them to the parliament, and they received the thanks of the House "for their good affections." Nor did they confine their interference merely to petitions, but, under sanction of an ordinance of parliament promising to them security against forfeiture of their indentures, they were inrolled into a sort of militia. They also took part in the restoration, and in the reign of Charles II. they were frequently engaged in tumults. The last serious riot in which they were concerned took place in 1668. On this occasion they assembled themselves tumultously together during the holidays, and proceeded to pull down the disorderly houses in the city. For this exploit, several of them were tried and executed for high treason.

In 1681, when Charles II. was desirous of strengthening his hands in every way against the corporation of London, he thought it necessary to endeavour to secure the favour of the apprentices, and sent them a brace of bucks for their annual dinner at Sadler's Hall, where several of his principal courtiers dined with them. The apprentices, however, were divided in opinion; for there were numerous petitions from them both for and against the measures of the court.

Subsequently to this time their union appears to have been gradually dissolved, and we do not find them again acting together in a body. After they had ceased, however, to form a separate class, the laws which had called them into existence, though partially repealed as to some trades, continued generally in force; nor was it until a very late period that the progress of more liberal opinions finally put an end to them. But the exclusive spirit which had dictated them was so far modified by the spirit of English liberty, that the monopolies upheld by them were never so strictly enforced, nor the evil of them so much felt in this country as on the continent. For not only were the apprentice-laws condemned by the liberal and speculative philosopher, but they found no favour in the courts of law. They were frequently reprobated by judges and legal writers; and Lord Mansfield denounced them as being "against the natural rights of man, and contrary to the common law rights of the land." Acting upon this view of the impolicy of the system, the decisions of the courts tended rather to confine than to extend the influence of the statute of Elizabeth, and thus the operation of it was limited to market-towns, and to those trades which were actually in existence at the time it was passed. And although in consequence of this doctrine, many absurd anomalies and inconsistencies were introduced, yet the exclusion of some manufactures, and particularly of the principal ones of Manchester and Birmingham, from the operation of the act, had probably a favourable effect in causing it to be less strictly enforced even against those who were held to be liable to it. It was proved by a mass of extremely interesting evidence produced before a committee of the House of Commons in 1814, that the provisions of the statute of Elizabeth neither were, nor could be, carried into effect in our improved state of trade and manufactures. An alteration in the law could therefore be no longer delayed. And though the question was brought before the legislature on a petition praying that the 5th Eliz. c. 4, might be rendered more effectual, the result was the passing of an act (54 Geo. III. c. 96) by which that statute, so far as it enacts that no person shall exercise any trade without having served a seven years' apprenticeship to it, was wholly repealed. There is in the act of 54 Geo. III. c. 96, a reservation in favour of the customs and bye-laws of the city of London, and of other corporate towns, but in general the necessity of apprenticeship, as a means of access to particular trades, is abolished, and a perfect liberty, in this respect, is established. Moreover by the act to provide for the regulation of municipal corporations (5 & 6 Will. IV. c. 76, s. 14), any persons may use any trade in boroughs, although not free of the city or borough, or of the trading company.

Apprenticeship, though no longer absolutely necessary, still continues to be the usual mode of learning a trade, and as such is recognised by law; it may therefore be useful to mention, in a summary manner, some of the leading provisions of the law upon the subject. By the common law, an infant, or person under the age of twenty-one years, being unable to contract any obligation except for his own benefit, cannot bind himself apprentice so as to entitle his master to an action of covenant for departing his service, or other breaches of the indenture. The statute of 5 Eliz. c. 4, ss. 42, 43, enacts that every person bound by indenture according to the statute, although within the age of twenty-one, shall be bound as amply, to every intent, as if he were of full age. But by these words of the statute, the infant is not so bound as that a remedy lies against him upon any covenant of the indenture; and it has therefore been a common practice for a relation or friend to be joined as a contracting party in the indenture, and engaging for the faithful discharge of the agreement. But by the custom of London, an infant, unmarried and above the age of fourteen, may bind himself apprentice to a freeman of London, and it is said that, by force of the custom, the master may have such remedy against him as if he were of full age, and consequently an action of covenant. Any person under the age of twenty-one years is, by 5 Eliz. c. 4, ss. 35, 36, compellable to be bound apprentice, if so required by any householder using half a plough of land in tillage. The same act also provides that the binding must be by indenture, so that binding by deed-poll, or by an agreement to execute an indenture, on a parol binding, have been held not to constitute an apprenticeship, though, by statute 31 Geo. II. c. 11, a binding by deed not indented enabled a person to gain a settlement, and now no deed is required to be indented.

By statute of 43 Eliz. c. 2, confirmed by 8 & 9 Will. III. c. 30, and by subsequent acts, the churchwardens and overseers of a parish, with the assent of two justices of the peace, might bind children of paupers apprentices till the age of twenty-one, and not only persons in husbandry and trade, but gentlemen of fortune and clergymen might be compelled to take them, subject to appeal to the sessions; but by the 7 & 8 Vict. c. 101, the powers for compelling persons to take parish apprentices were repealed; and under the same statute, all bindings of parish apprentices are now made by guardians of the poor (instead of churchwardens and overseers), and they need not be allowed by justices, but are subject to the rules of the poor-law commissioners. Parish apprentices may also be bound (7 & 8 Vict. c. 112; 14 & 15 Vict. c. 96) to the sea service. Various regulations have been made by several acts of parliament, and in particular by 56 Geo. III. c. 139, for ensuring that parish apprentices shall be bound to proper masters, and securing them from ill-treatment. The statute (14 & 15 Vict. c. 11) provides for the apprentices being periodically visited by the parish officers. Special provisions also exist, regulating apprenticeship in mills and factories, and in mines and collieries, and also in respect of chimney-sweepers. A settlement is gained by apprentices in the parish where they last resided forty days during the service (13 & 14 Car. II. c. 12). [POOR LAW; SETTLEMENT.]

An indenture cannot be assigned over, either by common law or equity, but by custom it may. Thus, by the custom of London and other places it may be done by a "turn-over." Parish apprentices may also (32 Geo. III. c. 57, s. 7), with the consent of two justices, be assigned over by indorsement on the indentures.

An indenture is determinable by the consent of all the parties to it; also by the death of the master, apprenticeship being a personal trust between master and servant. But it is said that the executor may bind the apprentice to another master for the remainder of his term. And if there is any covenant for maintenance, the executor is bound to discharge this as far as he has assets. In the case of a parish apprentice (32 Geo. III. c. 57, s. 1), this obligation only lasts for three months, where the apprentice-fee is not more than 5*l.*, and the indenture is then at an end, unless upon application by the widow or executor, &c., of the master to two justices, the apprentice is ordered to serve such applicant for the remainder of the term. By the custom of London, if the master of an apprentice die, the service must be continued with the widow, if she continue to carry on the trade. In other cases, it is incumbent on the executor to put the apprentice to another master of the same trade. By the Bankrupt Act, 12 & 13 Vict. c. 106, the bankruptcy of a master is a complete discharge of an indenture of apprenticeship; and where an apprentice-fee has been paid to the bankrupt, the court is authorised to order any sum to be paid out of the estate for the use of the apprentice which it may think reasonable.

A master may by law moderately chastise his apprentice for misbehaviour. He cannot, of his own accord, discharge him. But if he have any complaint against him, or the apprentice against his master, on application of either party to the sessions, by 5 Eliz. c. 4, or to two justices in the case of a parish apprentice, by 20 Geo. II. c. 19, and other acts, a power is given to punish or to discharge the apprentice, and in some cases to fine the master. If any apprentice, whose premium does not exceed 10*l.*, run away from his master, he may be compelled (6 Geo. III. c. 25) to serve beyond his term for the time he absented himself, or make suitable satisfaction, or be imprisoned for three months. If he enters another person's service, his master is entitled to his earnings, and he may bring an action against any one who has enticed him away. On the other hand, by the statute, 14 & 15 Vict. c. 11, masters or mistresses of apprentices or servants are legally liable to provide them necessary food, clothing, &c.; refusing or neglecting to do so, or assaulting them so as to endanger life, or permanently injure health, they are guilty of misdemeanour, punishable by imprisonment not exceeding three years.

In London, moreover, in case of misconduct by the master towards the apprentice, or by the apprentice towards the master, either party may summon the other before the chamberlain, who has power to adjudicate between them, and, upon the disobedience or refractory conduct of either party, may commit the offender to Bridewell.

The main objections to apprenticeship are, its interference with the property which every man has, or ought to have, in his own labour, and its encroachment not only on the liberty of the workman, but also of those who might be disposed to employ him, and who may safely be allowed to judge whether he is fit to be employed or not. To require in the more common mechanical trades the same length of apprenticeship as in the nicer and more difficult arts, is manifestly unnecessary and inexpedient; and it is obvious that long apprenticeships have a tendency rather to repress than encourage a love of industry, as an apprentice is excluded from the greatest incentive to voluntary labour, namely, a participation in the fruits of his exertions or skill. Most of these objections apply to apprenticeship as a necessary rather than a voluntary contract, and are of course removed by the present state of the law. At the age at which apprentices are usually bound some subjection to restraint is desirable; and, whether by being bound as an apprentice, or by working as a journeyman, a workman is most likely to gain a complete knowledge of his trade, and to acquire habits of industry, may be left to the determination of those who are practically interested in the question.

APPROACHES. This term is applied to the covered roads which are made by a besieging army to protect them from the fire of the place attacked. They consist generally of trenches excavated in the ground, the earth being thrown towards the fortress to screen them from the defenders. Occasionally, as on rocky or marshy ground, they are made by bringing masses of earth to the ground in bags, or by stuffed gabions, wool packs, or any other bulky material which can be easily obtained. For further particulars see SIEGE.

APPROVER. By our ancient law, where a person indicted for treason or felony confessed the crime charged in the indictment, he might be admitted by the court to reveal on oath the accomplices of his guilt, and he was then called an *approver*.

The court might either give judgment and award execution upon him, or admit him to be an approver. In the latter case a coroner was directed to receive and record the particulars of the approver's disclosure, which was called an *appeal*, and process was thereupon issued to apprehend and try the *appellees*, namely, the persons whom the approver had impeached as the partners of his crime.

As the approver, in revealing his accomplices, rendered himself liable to the punishment due to the crime which he had confessed, and was only respited at the discretion of the court, it was conceived that an accusation made under such circumstances was entitled to peculiar credit, and the accomplices were therefore put upon their trial without the intervention of a grand jury.

Here, however, as in other appeals [APPEAL], the accused were allowed to choose the mode of trial, so that the approver might be compelled to fight each of his accomplices in succession. But, unlike an appeal by an innocent person, the prosecution might be defeated by a pardon either to the approver or to the appellee.

If the approver failed to make good his appeal, judgment of death was given against him. If he succeeded in convicting the appellee, then he was entitled to a small daily allowance from the time of being admitted approver, and to a pardon.

The appeal by approvers had become obsolete before the abolition of it by parliament; and the present practice is to prefer a bill of indictment against all parties implicated in the charge, and to permit the criminal, who confesses his guilt, to give evidence against his companions before the grand jury. If upon the trial the demeanour and testimony of the accomplice is satisfactory to the court, he is recommended to the mercy of the crown. (2 Hawk., *Pleas of the Crown*, ch. 24; 'Blackst. Comm.' Mr. Kerr's ed., vol. iv. p. 390.)

APPROXIMATION, from the Latin, signifies a *drawing near to*. In mathematics, results are said to be found by approximation, when the process employed gives nearly, but not exactly, the result required.

Strictly speaking, the observed phenomena in every branch of experimental philosophy are approximations, more or less near, to the truth. Thus the distance of the sun, or the diameter of a planet, are only known approximately: but general custom does not sanction the application of the term to any "drawing near" in which the imperfection arises from error of the senses, or of instruments. It is only when the defects of mathematical analysis oblige us to be content with a formula which gives results only nearly true, that the latter are said to be approximate. To this part of the subject, then, we confine ourselves.

It may be stated as a general fact, that there are very few mathematical processes, except those of pure geometry, which give absolutely correct determinations, in which the answer obtained is neither more nor less than is necessary to satisfy the conditions of the question. But the fault is not in the processes themselves, but in the problems which it is necessary to submit to them, and in the nature of arithmetical, as distinguished from geometrical, magnitude. It is worth while, briefly, to elucidate this point. In geometry, the mind conceives one line or angle to differ from another by some magnitude of the same kind which can be *assigned*, and a magnitude is rather imagined to be given, than actually given. If we attempt to *construct* the line or angle of geometry, we must have recourse to approximation, and that of the roughest character, since the errors are as great as those of the senses. It is only by laying down the postulate that any line or angle can be assigned independently of all mechanical methods, that geometry becomes a science of absolute exactness. In arithmetic, on the contrary, the very first notion of numbers throws a theoretical difficulty in the way. We can imagine a line to grow or increase *continuously*; that is, in such a way that it shall not increase from one to two feet, without previously assuming every possible length which lies between one and two feet. This idea is forced upon us whenever we see points moving to or from each other. But is it therefore true, that every possible length which is greater than one foot and less than two, can be expressed by one foot and some determinate numerical fraction of a foot? This question reduces itself to the following. Let A D be

greater than A B (one foot), and less than A C (two feet); if B C be successively divided into two equal parts, three equal parts, four equal parts, and so on, *ad infinitum*, does it follow that some one or other of the subdivisions must of necessity fall upon the point D, previously taken at hazard? If we appealed to the evidence of the senses, we should certainly answer in the affirmative, for, though the finest compasses were used, we should soon find some point of subdivision so near to D, as not to be distinguishable from it by the severest test our senses could apply. But our mechanical points are minute solids, while the mathematical point has neither length, breadth, nor thickness. Conceive the latter, and the affirmative answer does not appear self-evident; for though the continuation of the points of subdivision is unlimited, the number of points which can be taken in the line is also unlimited. But we can demonstrably answer the question in the negative (see the 'Treatise on the Study of Mathematics,' by the Society for the Diffusion of Useful Knowledge, p. 81): as an instance, let B D be equal to the side of that square of which B C is the diagonal, or let B C be the circumference of that circle of which B D is the diameter. In neither case can one of the subdivisions of B C ever fall on D.

Here then is a fruitful source of the necessity of having recourse to approximation, since we cannot be sure that any required relation between concrete magnitudes is absolutely expressible in numbers. In fact, we may state the following as a result of experience, though, not so far as we know, capable of demonstration: numbers being taken at hazard, and submitted to any process which requires the solution of an equation higher than the first degree, the odds are greater than can be assigned against obtaining an absolute result without approximation. In a common table of logarithms, fixing at hazard upon any number, the odds are nearly seventeen thousand to one against choosing a number of which the logarithm can be exactly given.

This would appear to throw an air of uncertainty over almost all the conclusions of pure mathematics, and justly so, if it were not for the following truth, which, except so far as the labour of approximation is concerned, renders it practically immaterial whether a result is obtained exactly, or by approximation. Any equation whatsoever, which expresses the conditions of a possible problem, if not capable of exact solution, may yet be so far satisfied that a number or fraction can be found, which, on being tried in the given equation, shall produce an error smaller than any we may think it necessary to name at the outset. For instance, the ratio which the circumference of a circle bears to its diameter does not admit of an exact and absolute determination. If any two numbers be named, their ratio is either too great or too small. But supposing it asked to determine the circumference of a circle from its diameter so nearly, that the error shall not be so much as a foot for every hundred miles of diameter, or in that proportion. It can be shown to be more than sufficient for this purpose to multiply the diameter by 355 and divide by 113; which, if the diameter were 100 miles, would give 314 miles, 280 yards, and 1 foot: this, though too small, is within the conditions of the question, not being too small by one foot. Again, though it is impossible exactly to solve the equation $x^2=7$ or $x^2-7=0$, that is, to find a fraction which, multiplied by itself, shall make 7, yet naming any fraction, however small, at pleasure, for example, one millionth or ·000001, it is possible so to determine x, that x^2-7, though not absolutely *nothing*, shall be less than the proposed fraction, one-millionth.

It is not our purpose here to enter upon methods of approximation: no space which we could devote to the subject would suffice to explain any of them with sufficient detail to render them of practical use. We shall therefore content ourselves with giving a general view of one of the great methods, we might say, *the* great method, usually employed, and shall thereby, in succeeding articles, show the young mathematician that various methods, upon which he must have come in the course of his reading, contain a common principle, though disguised under the various forms of calculation which it is necessary to employ in different cases. We must now suppose the reader acquainted with the elements of the differential calculus.

When a number is given, and certain processes are also known, so that they can be performed either exactly or approximately, we are in possession of the solution of the following question—given the number, and the process, to find the result of the process. Hence immediately there results reason for inquiry into the inverse question—knowing the process, and the result of it, what was the number on which the process was employed? The way of finding this number is called the inverse process, and, if of sufficiently frequent occurrence, a name is given to it, and the rule for finding it is put into words, and arranged in its most systematic form. Thus the process of *squaring* or multiplying a number by itself, is known when multiplication is known, and the question is easily answered, what is the square of $2\frac{1}{2}$ or any other number, or what *results* from the process of *squaring* employed upon the *number* $2\frac{1}{2}$? From this arise such questions as the following:— The *result* of *squaring* is found to be 50; what was the *number employed?* This can only be answered approximately; that is, no number squared can give *exactly* 50, though one can be found, the square of which is as near 50 as we please. This operation occurs sufficiently often to receive the name of the extraction of the square root, and the rule for approximating to it is well known. We can now carry the generalisation a step farther, for the result of the last is to put a new process into our hands which we may consider as direct, since the means of performing it in all cases, approximately at least, have been found. We may now ask, what is the result of the process denoted by

$$x^2+\sqrt{x^3-1},$$

any number being substituted instead of x: but the inverse question —namely, suppose the above process to have been performed, and the result to be 20; what number was employed?—presents itself and requires new investigations. Neither the direct nor inverse process in this case has received a name; and it is evident that, name as many as we may, each addition will give new processes, require new inverse processes, and so on *ad infinitum.*

Previous to entering upon the process of approximation, it is necessary to inquire into the effect which a small change in the number employed would produce upon the result. We say a *small* change, because the changes of any magnitude require formulæ of great intricacy, compared with small changes. The consideration of the effect of such changes is, among other things, the object of the DIFFERENTIAL CALCULUS; into which we can here enter no further than to state, that in connexion with every process it discovers others, which we shall here call by the names of the *first* derived process, the *second* derived process, &c.; the two first of which are indispensable, the first for obtaining the approximation, the second for ascertaining the degree of accuracy to which the approximation has been carried. These *derived* processes (as we here call them) are the first and second differential coefficients. [DIFFERENTIAL CALCULUS.]

Let $f x$ represent the required process or FUNCTION. Let $f' x$ and $f'' x$ represent its first and second derived functions. We suppose this notation known to the reader; but any one who has studied algebra may be prepared to follow us by reading the first thirteen pages of the treatise of the Society for the Diffusion of Useful Knowledge, entitled 'Elementary Illustrations of the Differential and Integral Calculus.' If the operations which $f x$ indicates to have been performed upon x, be successively performed on a and $a+h$, giving fa and $f(a+h)$, it may be proved that

$$f(a+h)=fa+h\ f'a+\frac{h^2}{2}f''(a+\theta h) \quad \text{(A)},$$

where θ is a fraction less than unity, or θh is less than h. This rule only admits of exception where fx is such that either $f''x$ becomes very large, or $f'x$ very small, for some value of x lying between a and $a+h$; and since in approximations h is a very small quantity, this will rarely happen, and when it does happen, the results of an attempt to approximate will soon point it out. Let us now suppose that we wish to find x in such a way that $fx=0$. Every case may be easily reduced to this: for example, to solve $x^2=7$ is to find or approximate to a value of x, which makes $x^2-7=0$. The first step is to find by trial some value of x which will very nearly satisfy the proposed condition, that is to find a, so that fa shall be small. No general rule can be given for this part of the process, which is, however, easily done in most cases. To carry an example with us, let us suppose it required to solve the equation:

$$x^3-2x=5$$

or to make

$$x^3-2x-5=0$$

Here fx is x^3-2x-5, and by the rules of the differential calculus, $f'x$ is $3x^2-2$, and $f''x$ is $6x$. We soon find that there is a root between 2 and 2·1, for if $x=2$, then x^3-2x is 4, and if $x=2·1$, it is 5·061; the first less than 5, the latter greater, but not much. We therefore take 2·1 as the approximate value of x found by trial.

Returning now to equation (A), let us suppose a the approximate value increased by h, in such a way that $a+h$ shall be the real value of x required, or $f(a+h)=0$. This gives

$$h=-\frac{f a}{f' a+\frac{1}{2}h f''(a+\theta h)} \quad \text{(B)},$$

in which h is not, strictly speaking, determined, because it occurs on the second as well as the first side. But h is small, because a is nearly the value required, and therefore we may approximate to the value of h from (B) by rejecting the small term

$$\tfrac{1}{2}h f''(a+\theta h)$$

from the denominator of the fraction, which gives

$$h=-\frac{fa}{f'a}$$

for an *approximate* value of h: so that the new value of x obtained from the step just made is

$$a-\frac{fa}{f'a}.$$

With this new valne of x we may recommence the process, and find a new correction; and so on.

Resuming the example, we find putting $a=2·1$,

$$fa=a^3-2a-5=·061,$$
$$f'a=3a^2-2=11·23,$$
$$h=-\frac{·061}{11·23}=-·0054 \text{ nearly},$$
$$x=a+h=2·0946 \text{ nearly}.$$

Trying this value in x^3-2x-5, we find it ·005, nearly; less than the tenth part of its preceding value. With 2·0946 for a, the process must be now repeated.

The degree of approximation thus obtained may be estimated as follows, though we can only very briefly explain it to those who have no more practice in the differential calculus than we have hitherto supposed. Resuming the correct equation (B), we see that, if we call fa, as obtained, a small quantity of the first order, $(fa)^2$ of the second, and so on, then h will be of the same order as fa, unless $f'a$ be also of that order, which is one of the excepted cases. Hence, in rejecting θh, we reject only quantities of the first order from the term $f''(a+\theta h)$, or of the second from $\frac{1}{2}h f''(a+\theta h)$, or of the *third* order from the whole fraction, since fa is itself of the first order. This will appear from the development of the second side of (B) by common division. Thus rejecting θh, and developing

$$-\frac{fa}{f'a+\frac{1}{2}h f''a}$$

as far as terms of the second order, we have

$$h=-\frac{fa}{f'a}\left(1-\frac{f''a}{f'a}\frac{h}{2}+\text{\&c.}\right),$$

in which, if on the second side we write $-\frac{fa}{f'a}$ for h, which rejects terms of the second order only, we still reject terms of the *third* order only in the value of h. Hence

$$h=-\frac{fa}{f'a}\left(1-\frac{1}{2}\frac{f''a\,fa}{(f'a)^2}\right) \text{ nearly},$$

and its ratio to its preceding value $-\frac{fa}{f'a}$, is

$$1-\frac{1}{2}\frac{f''a\,fa}{(f'a)^2},$$

whence $-\frac{1}{2}\frac{f''a\,fa}{(f'a)^2}$ represents roughly the greatest part of itself, by which the correction $\frac{fa}{f'a}$ may be erroneous, the sign indicating whether it is too small or too great. In the preceding example, where $a=2·1$, and where

$$fa=a^3-2a-5=·061,$$
$$f'a=3a^2-2=11·23,$$
$$f''a=6a=12·6,$$

the preceding fraction is roughly $-\frac{1}{32}$, so that the correction ·0055 may possibly be one thirty-second of itself too great, or about ·0002 too great.

This method does not appear to be of much use for the second approximation; but becomes more powerful at every succeeding step. Whatever number of correct decimal places is obtained at the end of any one of the successive approximations, it is, roughly speaking, doubled by the next; since the second term of the preceding development of h, being

$$\frac{1}{2}\frac{f''a}{(f'a)^3}\cdot(fa)^2,$$

is of the same order as the square of h, or of the same order as

$$\left(\frac{fa}{f'a}\right)^2.$$

In treating the various articles, DIVISION, SQUARE ROOT, &c., EQUATION, we shall show that principles analogous to the preceding have been adopted in the rules for approximating.

Various methods of approximation are found in the Hindoo Algebra; but, as far as we can find, Vieta is the first who generalised the main principle so far as to connect the approximate solution of equations with the particular cases of division and the square root, which were known before Hutton, in his 'History of Algebra' (see his Tracts), attributes this extension to Stevinus, but on searching the works of the latter, we cannot find anything which, in our opinion, justifies the assertion. The connexion of the arithmetical rules, in which successive figures are successively found, with the preceding, will not at once be obvious; but our limits oblige us to refer to INVOLUTION AND EVOLUTION on this point. Newton first applied the theory of derived functions directly to algebraical equations; and the method was further extended by Lagrange.

APRIL, the fourth month of the year, consists of thirty days, which was the number said to be assigned to it by Romulus. Numa Pompilius deprived it of one day, which Julius Cæsar restored, and which it has ever since retained. In the original Alban or Latin Calendar, April held the first station, and then consisted of thirty-six days. (Pitisci, 'Lexicon Antiq. Roman.' tom. i. p. 129; Brady's 'Clavis Calendaria,' p. 67.) Its name is usually considered to have been derived from *aperire*, to open; either from the opening of the buds, or of the bosom of the earth in producing vegetation. The Anglo-Saxons called it Ooster or Easter-Monath. In this month the sun travels through parts of the signs of Aries and Taurus, that is to say, of those parts of the ecliptic which astronomers designate by those names. The real motion of the sun among the constellations is through parts of Pisces and Aries. [PRECESSION; ZODIAC.]

APRIL CEREMONIES. The custom of making fools on the first of April is a practice well known in England, France, Sweden, and probably in other countries of Europe; and it is believed to be connected with an immemorial custom among the Hindoos, held near the same period in India, towards the end of March, called the Huli Festival, when mirth and festivity reign among the Hindoos of every class, and people are sent upon errands and expeditions which end in disappointment, and raise a laugh at the expense of the person sent. ('Asiat. Res.' vol. ii. p. 334.) In Europe the practice is similar: the fun consists in deceiving a person in any not injurious manner, such as "sending them on a sleeveless errand," as Addison terms it in the 'Spectator.'

The origin of this April custom seems unknown everywhere, though Bellingen, in his 'Etymology of French Proverbs,' considers that it may possibly have an allusion to the mockery of our Saviour, about this time, by the Jews: a conjecture which is in some degree paralleled, if not corroborated, by the custom of Lifting in the Easter holidays, undoubtedly intended to represent our Saviour's resurrection.

In England, the first of April is usually termed 'All Fools' Day,' and the person imposed upon, an April Fool. In France this person is called a 'Poisson d'Avril,' *i.e.*, a mackarel, or silly fish. In Scotland, 'an April Gowk.' In Portugal, according to Southey, the like practice prevails on the Sunday and Monday preceding Lent. Maurice, 'Indian Antiq.' vol. vi., p. 71, speaks of the Huli Festival as the celebration of the period of the vernal equinox.

A PRIO'RI and A POSTERIO'RI; two logical terms, signifying, literally, 'from a thing before,' and 'from a thing after.' They are applied to distinguish between two different methods of reasoning; the first, *a priori*, in which the conclusion is drawn from previous arguments, which render it unnecessary to examine the particulars of the case in point; the second, *a posteriori*, in which the thing to be proved is examined, and made the source out of which the reasoning is drawn. It must be noticed, however, that these are rather terms of common conversation and writing, than of logic, properly so called; so that they are seldom noticed by writers on that science. The use of them is in general very vague, and the consequence of any attempt to define them very strictly would be either to make out *a priori* reasoning to be altogether impossible, or to throw insuperable difficulties in the way of finding where it ends and the other begins. In common language, we reason *a priori* when we infer the existence of a God from the general difficulties in the supposition of the existence of what we then call the creation, on any other hypothesis; but we reason *a posteriori* when we infer the same from marks of intelligent contrivance in this particular creation with which we are acquainted.

The term *a priori* is, however, frequently used in a sense which implies "previous to any special examination." As when a sentence begins with "*a priori* we should think," &c &c., which in most cases will be found to mean nothing more than an expression of the leaning which the speaker found his mind inclined to, when he had only heard the proposition, and before he had investigated it.

All *a priori* reasoning is dubious, to say the least: in but very few cases, if any, are we able to say we know sufficient beforehand to render this sort of argument safe. Pure mathematics and logic are capable of establishment *a priori*, and no other sciences whatever. But though the method is of little effect towards the establishment of most kinds of truth, it is highly effective in its discovery; indeed, by the very nature of its definition, it must be the guide which points out the probable direction in which the thing sought may be found. Columbus went to look for the continent of America, in consequence of certain convictions of his own, derived from *a priori* reasoning. So far he was right: but had he contented himself with writing a quarto volume to prove the existence of the new continent, by reasons which were only strong enough to make it right to look for more, some less imaginative *a posteriori* reasoner would have been the real discoverer.

APSE, or APSIS, in Architecture, the semicircular termination to the choir of a cathedral or church. Formerly it was applied to the entire choir, or a portion railed off. The apse corresponds to the hemicycle, or curved recess in which was the tribunal in the ancient Roman Basilica; and hence in Roman Catholic countries the bishop's throne is always placed within the apse,—the church being regarded as the tribunal where the bishops sat to administer spiritual justice, penance to the guilty, and the eucharist to the absolved. [BASILICA.] The term apse is also applied to the semicircular terminations of aisles, and sometimes to similar terminations of transepts. In the cathedrals of Italy, Germany, and France, the apsidal termination is very general. In England, the cathedrals of Canterbury, Rochester, Norwich, and Peterborough, Ripon Minster, and Westminster Abbey, as well as several parish churches, have apsidal terminations; and in some instances, as at Gloucester and Worcester cathedrals, the crypts retain the apsidal form, though the apse itself has been removed at a period subsequent to the original foundation of the church. In some French cathedrals a great complexity of form is given to the apse by the substitution of a range of columns for the semicircular wall, beyond which is a series of chapels. For this form, Mr. Fergusson ('Handbook of Architecture,' p. 618) proposes the vernacular term *chevet*. He says, "The apse, properly speaking, is a solid semicylinder, surmounted by a semi-dome, but always solid below, though generally broken by windows above. The *chevet*, on the contrary, is an apse, always inclosed by an open screen of columns on the ground-floor, and opening into an aisle, which again always opens into three or more apsidal chapels. This arrangement is so peculiarly French, that it may properly be characterised by the above French word, a name once commonly applied to it, though latterly it has given way to the more classical but certainly less suitable term of apse." But the term apse (*abside*) is that generally applied to it by French architects and writers on architecture.

APSIDES, a Greek term, used to signify those points of a planet's orbit in which it is moving at right angles to the line drawn to the primary. These points are also those of greatest and least distance from the primary. [APOGEE and PERIGEE for the moon and sun; APHELION and PERIHELION for the earth or a planet.]

AP'TERAL, a term used in architecture with reference more particularly to a mode of arrangement peculiar to the temples of the ancient Greeks and Romans. It is formed from a Greek compound term, signifying 'without wings;' and in this sense it is applied to a temple having prostyles, or porticoes of columns projecting from its fronts or ends, but of which the columns do not extend laterally, and run along the flanks from one end to the other, so as to make it *peripteral*. [TEMPLE.] Modern churches which have porticoes, though some of them are professedly on the Greek model, are, nevertheless, generally, illustrations of the apteral arrangement, and of these that of St. Pancras in London may be best referred to as an example.

APUS (Constellation), from the Greek ἄπους, without feet, used to signify the bird of Paradise, the *Avis Indica* of Linnæus, which was formerly believed to have no feet. It is a constellation introduced by Bayer, and lies too near the south pole to be visible in our hemisphere. It is surrounded by Octans, Pavo, Triangulum Australe, and Cameleon. The following is a classified enumeration of its principal stars :—

Magnitude.	Number of Stars.
4	1
4·5	1
5·	1
5·5	2
6	6
	11

Hence the total number of stars visible to the naked eye in this constellation amounts to 11. The principal star is thus designated :—

AQUAFORTIS. [NITRIC ACID.]

AQUA REGIA. [NITROHYDROCHLORIC ACID.]

AQUA'RIUS (Constellation), the Water-Bearer, one of the twelve zodiacal constellations. Its Greek name is Ὑδροχοεὺς, the Water-Pourer. In the Indian zodiac it is simply a water-jug, the name of which, according to Legentil, is Coumbam, and the same in the Arabic. In the Egyptian, it is a male figure holding two urns, from which the water flows. The mythology of the Greeks refers the Water-Bearer in different places to the fables of Deucalion, Ganymede, Aristæus, and Cecrops. Its probable origin however, whether we place the origin of the zodiac in India or Egypt, is the watery season of the year in which the sun was in this sign. Dupuis, who supports the latter opinion, thinks that Aquarius, as well as Capricornus and Pisces, refer to the months of the year during which the inundation of the Nile took place. Legentil, who advocates the former, imagines that they represent the rainy season which is absolutely necessary for the growth of the rice-crops.

The constellation Aquarius may be found in the heavens by producing southward a line drawn through the bright stars in the head of Andromeda and the wing of Pegasus. This line passes through the two brighter stars in Aquarius, α and β, situated in the two shoulders. The middle point between these two shoulder stars is on the meridian at 12, 10, 8, and 6 P.M., in the months of August, September, October, and November respectively, at an altitude of about 35 degrees.

A distinction must be drawn between the constellation and the sign of the Zodiac. [PRECESSION.] The latter is the part of the ecliptic which begins at the horn of the constellation Capricornus and ends in the middle of the body of that of Aquarius, comprising the arc of longitude between 300° and 330°, and forming the sun's path between January 20th and February 20th.

The following is an enumeration of the principal stars in this constellation, classified according to the order of their apparent magnitudes:—

Magnitude.	Number of Stars.
3rd	3
4th	4
5th	18
6th	73
	98

Hence the number of stars in this constellation which are visible to the naked eye amounts to 98. The following are the various designations of the stars down to the 4th magnitude inclusive:—

Character.	No. in Catalogue of Flamsteed.	No. in Catalogue of British Association.	Magnitude.

λ	73	7970	4
δ	76	7980	3

AQUATINTA ENGRAVING. The word aquatinta is a compound of two Latin words, *aqua* (water) and *tinctus* (stained), by which is implied that this mode of engraving is an imitation of water-colour or India-ink drawings. The inventor, a German artist named Le Prince, was born at Metz in 1723. Although capable of very pleasing, and indeed of very beautiful effects, aquatinta engraving has fallen into comparative disuse: partly no doubt owing to the facility which it affords for the production of inferior plates, but more to the introduction of lithography. Yet, as the very facility with which it can be executed, renders it especially valuable in places where skilful engravers are not readily met with, and as it appears not unlikely from some of the experiments of M. Niépce de St. Victor and others, that at least some stages of the aquatinta process may be of value in heliographic (or photographic) engraving, a subject likely to engage a good deal of attention among amateurs, we think it may be convenient to give a description of the process in sufficient detail to enable any one tolerably acquainted with art to produce for himself an aquatinta engraving.

Le Prince's method was to sift the common black resin, when tied up very loosely in a muslin bag, over the plate, so as partly to cover the surface with the particles. It was then fixed by a moderate heat sufficient to make the dust adhere without fluxing or becoming an even varnish: he thus formed a granulated surface on the plate, usually called a *ground*, which suffered very little from the action of the diluted acid, yet allowed it to corrode very freely in the small spaces left between the grains of the resin. In recent methods the ground is prepared by dissolving the black resin in the highest rectified spirits of wine (alcohol), and then pouring the mixture over the plate, the quantity of resin determining the coarseness or fineness of the grain: the plate here referred to is the ordinary copper-plate used by engravers, but the directions apply equally to a steel plate.

When the ground is thoroughly dry, the surface will be of a bright copper colour, and in a few hours will be ready for use. A warm room is requisite for this operation in cold weather, but if not, the early morning must be taken. Dust should be most carefully avoided. A small plate may be held on the points of the fingers and thumb of the left hand whilst the ground is laid, and be gently moved about till the ground has granulated or formed; this aids the better formation or crystallisation of the grain. Before a ground is laid, the plates are to be well cleansed with dry whiting and a dry linen cloth, it being absolutely necessary that the plate should have a very perfect polish, for without this the granulation cannot be well effected. Any of the resinous gums will, with spirits of wine, make a ground, but the black resin is generally preferred. Modern aquatinters use a composition for painting the forms of leaves of trees, or other objects, where the trouble of surrounding the forms by a varnish would be too great. This composition is made of moist sugar or treacle added to the same bulk of whiting, and ground well on a slab with a little water; a very small proportion of gum Arabic or gamboge may be added. When this composition is used, it must be thoroughly dry before the varnish is passed over it; the varnish also must be allowed time to dry, after which, cold water poured on the plate will in a few minutes bring off all the composition and the varnish which had passed over it, leaving the forms perfect and the ground in those places free to receive the acid again—the remainder of the plate being permanently *stopped out* by the varnish. This varnish is either Canada balsam or turpentine varnish mixed with a little lamp-black and spirits of turpentine; with this also the margin of the plate is to be varnished, leaving a narrow strip of the ground for trials. These trials are made, after each time that the acid has been on the plate, by taking off a small portion of the strip with spirits of turpentine, cleaning the place well, and then rubbing in with the finger a little powdered white lead; this process will give a good idea of the actual and comparative strengths of tints. It is only by these trials that the aquatinter knows what he is doing, for the acid varies so greatly with the weather, that what might be considered very weak in a cool morning, becomes very strong towards the evening; for this, and other obvious reasons, if the room be kept at an equal temperature, the work will advance with much greater certainty than when it varies by the changes of weather.

When the ground is dry, the design intended to be engraved is made on it; this is done in the following manner:—The design is first copied on very thin transparent paper, called tracing-paper; between this tracing and the prepared ground on the plate a thin sheet of paper is placed, which has been rubbed over with lamp-black, or vermilion, and sweet oil; every line of the design is then gone over with an instrument called a blunt point, with a moderate pressure, and is thus transferred to the ground so securely that the acid cannot destroy it.

Before the acid is poured on the plate, a border or wall of wax, about an inch in depth, is placed round the margin of the plate. The bordering wax is made by melting together one pound of burgundy pitch, half a pound of bees'-wax, and a wine-glassful of sweet oil; when melted, to be poured into cold water and worked into small cakes. When wanted, these cakes are put into lukewarm water and made into small rolls like a sausage, then flattened, and one of the edges being a little melted at the fire, is to be pressed close to the plate with a wet finger, making a spout at one corner; this should be well performed, or the acid will get beneath it and occasion much mischief. In order to make the wax adhere, the plate should be made as warm as the hand of the operator.

The plate being so far made ready, the completion of the design is resumed by stopping out the highest lights on the edges of clouds, water, &c., with a mixture of Canada balsam or turpentine varnish, and the *perfectly* impalpable oxide of bismuth (bismuth is preferred on account of its weight); these are mixed with a spatula on a slab, and used with a small sable brush, diluting the varnish occasionally with spirits of turpentine. Next pour on the acid, which has been prepared by mixing one-sixth of a pint of the strongest nitric acid to five-sixths of a pint of water; let it remain, according to its strength, from half a minute to a minute, then pour it off, and wash the plate three or four times with clean water, and dry it with a clean linen cloth or a pair of bellows: the last is the best, if the stopping-out varnish should not be perfectly hard. If on trying the strip the tint is found not to be sufficient, repeat the acid for another half minute, and then proceed. The colour of the bismuth varnish must be changed for the second stopping-out, by adding a little chrome yellow, vermilion, or lamp-black, or any other colour that is not destroyed by the acid. The colour is to be changed after each application of the acid, that the engraver may remember in what places he has carried forward his work, what tints have been softened at their edges, &c.

It is impossible to give a scale of times for each employment of the acid, but the following may serve as a guide. If the first tint has half a minute, the second may take three-quarters, the third one minute, the fifth one minute and three-quarters, the sixth two minutes and a-half, the seventh five minutes, the eighth twelve minutes, &c. The acid should be strengthened a very little after each application; and it may be so equally done that the above proportions will serve very well as a general rule, depending on the strength of the tints required. When the ground changes to a gray colour it is beginning to fail, and must be taken off by heating the plate till the bordering wax will lift off; after this, sweet oil is applied to the whole surface, and a brisk heat beneath the plate will bring off all the different varnishes with a linen cloth; then an oil-rubber, made of fine woollen cloth, rolled up hard and the end cut off, applied with sweet oil, will take out the stains; tints which are too strong may be softened or even rubbed out. Perhaps it need not be added, that a single grain of sand or any other hard substance under the rubber will ruin the whole work. Gradations in skies, &c., are sometimes made in this manner, though more generally by pouring the acid on slowly, beginning at the darkest corner. It will frequently happen that some portions of the varnishes will become so hard, that the common method will not stir them; in this case a little of the oil of spike lavender applied with the finger is quite certain to produce the effect. The plate is now cleaned with spirits of turpentine and sent to the printer to prove, after which it is to be exceedingly well cleaned with turpentine, &c., and another ground laid; this should be done in such a manner as to make the grains fall exactly on the granulations of the former ground, which is called *re-biting*. It is done by making the ground much stronger than was used before. Fortunately, the liquid ground has a natural tendency to granulate upon the same places as before, and when the acid is again applied it will act in the same interstices as before, and only wants a little care to make it answer. The process for the second ground is the same as for the first; re-touching with the acid those tints which require more depth, and stopping out those parts that are sufficiently dark. Another proof must be taken, and the plate then finished with the burnisher, which some use with oil, but others prefer to use dry, previously filling the whole plate with powdered white lead, by which it can be seen how much has been burnished down, according to the quantity of colour left in the plate.

AQUA TOFA'NA, a poisonous fluid invented about the middle of the 17th century by an Italian woman of the name of Tofana. This woman, who resided first at Palermo, and afterwards at Naples, was one of the most celebrated of a class of persons known under the name of Secret Poisoners, who in ancient times were believed to possess the power of destroying life at any stated period, from a few hours to a year; and who, during the 16th and 17th centuries, were regarded in all the nations of Europe with extraordinary terror. In the year 1659, during the pontificate of Alexander VII., it was observed at Rome that many young married women became widows, and that many husbands, suspected to be not agreeable to their wives, died suddenly. The government used great vigilance to detect the poisoners. Suspicion at length fell on a society of young wives, whose president appeared to be an old woman, who pretended to foretel future events, and who had often predicted very exactly the death of many persons. By means of a crafty female, their practices were detected; the whole society were arrested and put to the torture, and the old woman, whose name was Spara, with four others, were publicly executed. It appears that Spara, who was a Sicilian, derived her art from Tofana at Palermo, the latter selling the poison, which hence acquired the name of *Aqua della Tofana*, in small glass phials with this inscription,—"Manna of St. Nicholas of Barri," and ornamented with the image of the saint. Though this infamous woman lived to an advanced age, she was at length dragged from a monastery, in which she had taken refuge, and put to the torture. She confessed that she had been instrumental to the death of no less than 600 persons.

The dose of her poison was from four to six drops; yet though in this state of concentration its nature could not be detected, it was subsequently discovered to consist of a solution of arsenic; but so little was that age acquainted with the art of chemical analysis, that they had no means of detecting a solution of arsenic so highly concentrated that from four to six drops was a mortal dose; whereas, at present, even when arsenic has been dissolved in the stomach and mixed with vegetable and animal fluids, it may be reduced to its metallic form, and made to exhibit all the physical properties of the metal to the *naked* eye with as great distinctness as in any quantity, however large, *when only the twentieth part of a grain has been procured.* Modern chemistry therefore has deprived the poisoner by arsenic of all chance of escape by concealing or disguising the poison he administers.

AQUÆDUCT, or AQUEDUCT (*aquæ ductus*), the channel or passage for conducting water; of late years, however, the word *conduit* has been more commonly used to express the generic idea of a conducting passage, whilst the word aqueduct has been applied specifically to the class of structures which perhaps it would be more correct to call AQUEDUCT BRIDGES. As, however, this specific signification of the word has some advantages, it will be hereafter adopted in this Cyclopædia, and the following notice of Aqueducts will be devoted exclusively to an investigation of the practice of ancient and modern engineers, in the construction of bridges for the purpose of conveying streams of water above the surface of the ground from one comparatively high point to another. The laws of the flow of water in *conduits* (whether of masonry, open or covered, or of earthwork, wherein the water flows simply by the effect of gravitation; or of closed pipes, wherein the flow is effected by the pressure at the entry), will be discussed under the articles CONDUIT and WATER PIPES; whilst the investigation of the contrivances for the conveyance of water for the supply of town populations will be reserved to the article WATER SUPPLY.

It does not appear that either the Assyrians, or the Egyptians, executed any important works of the kind under consideration; for although unquestionably the systems of irrigation they adopted, and some pictorial representations in the sepulchral monuments of the Egyptians would lead us to believe that they were acquainted with the leading principles with respect to the flow of water, and were even aware of the effects of hydrostatic pressure, no remains of the aqueducts executed during the periods of the independent existence of the national governments of those countries have survived to our days. In Greece, and in Asia Minor, there are some remains of aqueducts; but the style of their construction would rather lead to the belief that they were erected subsequently to the Roman conquest; and, indeed, their outlines more closely approximate to the principles of Latin, than they do to those of Hellenic, art. The most authentic example of a Greek aqueduct is supposed to be the one described and figured by Mr. G. Rennie, in the Proceedings of the Institution of Civil Engineers, Jan. 16th, 1855; and it is the more interesting from the fact of its illustrating the practical application of the principle of the reversed syphon at a very early period in the history of art. The valley near Patara on the coast of Lycia, where this aqueduct was erected, is about 250 feet deep, and 200 feet across; and in it a wall of loose rubble masonry, at the bottom of which is left a small rough arch for the passage of the stream flowing in the ravine, has been formed terminating with a series of wrought stone blocks, well cramped together, closely jointed, and bedded in cement. These blocks are laid in a curved line, with its chord on the upper side; and they were perforated with a circular hole 13 inches in diameter. It is said that at Syracuse there are also remains of aqueducts of Greek construction, and that near Antioch an important work of this description was erected during the reigns of the Seleucidæ. But the mode of arching introduced in the latter work is so decidedly in the style of the Roman engineers, that it is hardly possible to attribute this monument to any one else than to the masters of the ancient world; just as it is necessary for the same reason to attribute to them the construction of the aqueduct of Mytelene.

The Roman government appears, at a very early period of its existence, to have felt the necessity for supplying large quantities of pure water to the inhabitants of the great centres of population submitted to its sway; and naturally it executed a series of important works for the supply of the Eternal City itself. Rome, in fact, was built on the banks of the Tibur, a stream so turbid as to merit and receive the name of the 'Flavum Tibrim;' and the quantity of water obtainable from wells sunk in the alluvial formations of the valley was soon found to be insufficient for the continually increasing population. About the year 312 B.C., then, Appius Claudius erected the first conduit through which the waters, afterwards known as the Aquæ Appianæ, were led into Rome. From that period to the close of the republican era, several other great works of this description were erected; such as the Anio Vetus about 273 B.C.; the Aqua Marcia about 146 B.C.; the Aqua Tepula about 127 B.C.; this last conduit was subsequently increased in importance by the addition of the Aqua Julia, in the year 35 B.C.; and in the very earliest days of the empire, Agrippa increased the supply of water in the eternal city by leading into it the Aquæ Virgo, Alsietina, and Augusta. At later periods the Aquæ Claudia, Anio Vetus, and Alexandrina were conducted to Rome, and thus added to the already copious supply of water it possessed. From the local conditions of the city, and of its neighbourhood, the streams thus diverted were forcedly brought from a great distance; and they arrived in the alluvial plain of the Tibur at a considerable elevation. It seems that the total lengths of the various conduits formed previously to the end of the first century of our era, was about 456,987 yards, of which 4930 yards were supported on a solid substructure, and not less than 53,421 yards were carried by aqueducts, in the limited sense of the word now adopted, which were frequently from 80 to 100 feet in height. In the provinces also the Roman engineers erected numerous important works of the same description, amongst which may be cited the aqueducts near Nîmes, Metz, Luynes, Fréjus, Trèves, Arceuil, Segovia, Tarragona, Evora, Merida, Carthage, Constantina, Tunis, Cairo, &c.; whilst at a later period of their rule they erected some ruder, but still colossal, aqueducts for the supply of Constantinople.

The practice of the Roman engineers in the construction of aqueducts, appears to have been to avoid large openings when the length between the sides of the valley was considerable. They appear to have been induced to adopt this principle, on account partly of their desire to avoid expense in foundation works, and partly on account of the difficulty they must have encountered in framing large centres such as should be able to carry the weight of an arch of considerable span, from the high price and the rarity of wrought iron. Whatever were their determining motives, the ruling dimensions they adopted were, for the openings, when dressed stone or ashlar was used, between 24 and 50 feet; though in the case of the Pont du Gard, the span of the largest arch is 80 feet; and in some of their road bridges even greater openings were admitted, as in the bridge of Alcantara, which has a span of 101 feet, and in that of Narni, which has a span of 139 feet. When the material employed was a small rubble stone, with ashlar bond courses, the spans usually varied from 18 to 36 feet; and when rubble or brick-work alone were used, the spans were limited to 24 feet, as a maximum, and were usually made from 15 to 18 feet. The width of the aqueduct varies from $\frac{1}{2}$ to $\frac{1}{4}$ of the openings, and the thickness of the piers from $\frac{1}{3}$ to $\frac{1}{5}$ of the span, though there are many examples in which they are made equal to the latter. When the height was considerable the aqueducts were built in tiers; but until the clear height under the key-stone attained 80 feet, the Roman engineers do not appear to have hesitated in executing such works with only one range of arches; when that height became from 90 to 160 feet, it was customary to construct two ranges of arches; and when it became from 180 to 250 feet three ranges were introduced. Their engineers seem also to have studied carefully the laws of perspective in designing these structures; for the proportions of the respective ranges of arches are almost always such as to produce the most agreeable effect upon the eye. The height from the ground to the underside of the first tier was usually made equal to $2\frac{1}{4}$ times the opening of the arches; the distance from the underside of the key to the top of the first horizontal line was made about $\frac{1}{3}$ the opening; the second row of arches was made about $\frac{1}{4}$ less in height than the first, and the third row $\frac{1}{4}$ less than the second. In the erection of the great modern aqueduct of Caserta, Vanvitelli neglected to observe these laws of perspective, and he made the upper tier of arches loftier than either of those beneath it; thus entirely marring the effect of what would otherwise have been a very fine monument.

But though the Roman engineers thus habitually resorted to the construction of aqueducts when they were compelled to cross deep valleys, they unquestionably did so from motives of economy, or from dread of deposition in the pipes, rather than from ignorance of the laws of hydrostatics. Gauthey gives a description of a lead pipe dredged from the bed of the Rhone, which had evidently formed part of a reversed syphon in the course of the conduit of Arles; but the most remarkable instance of the use of such reversed syphons by the Romans, in connection, it is to be observed, with ordinary aqueducts, is the one described in Delorme's 'Recherches sur les Antiquités de Lyon.' In this case the water brought from the Mount Pila is carried across several valleys, by means of thirteen aqueducts and three syphons; the first of which syphons, between the hills of Soncieu and Chaponest, is laid in a valley about 2600 feet across, and 217 feet deep; the second between Baunan and St. Foy, in a valley 3458 feet wide, and 325 feet deep; and the third between St. Tranée and the gate of Trion. A description of the Soncieu syphon is added; but it may be important here to observe, that a great deal of the interest attaching to this work arises from the singular illustration it affords of the state of the metallurgic arts amongst the Romans.

The water is admitted, on the upper side, into a reservoir of masonry, in the walls of which are inserted, at about 10 inches from the floor, nine lead pipes, 8¾ inches diameter and 1$\frac{1}{16}$ inches thick. These pipes are carried down the side of the valley on a species of substructure, arched in some places, so as to preserve a regular inclination; they are of the same diameter, as at the commencement, for a distance of 81 feet, and they then bifurcate into pipes of 6 inches diameter each. The eighteen smaller pipes are continued to the bottom of the syphon; but instead of descending quite to the lowest part of the valley, they are carried across an irregular depression of the latter on an aqueduct of about 80 feet maximum height; so that in fact the descending limb of the syphon is only about 164 feet in vertical height, and the descending limb is about 142 feet 2 inches. Midway in the ascending limb, the two 6-inch pipes are re-united into 9-inch ones, and the latter pour the waters they convey into a small reservoir corresponding with the one on the descending side. The Baunan syphon was deeper than the Chaponest one,—in fact, the dip of the descending limb was 282 feet; and therefore the diameter of the pipes at starting was smaller. The St. Tranée syphon was of considerably less importance than either of those above mentioned. Count Caylus, who examined the remains of these pipes very carefully, states that they contained so enormous a quantity of lead, that, even in his day, it would have been worth at least 500,000*l.*: what it must have cost in the time of Claudius Cæsar it would be impossible to say. The engineers of the Ponte dell' Arcate, on the conduit which supplies Genoa with water, adopted, in 1782, precisely the same system of syphon aqueduct thus described as having been used by the Roman engineers at Lyon, substituting cast iron however for lead; and a modification of the same system was even applied by the engineers of the Croton Waterworks, New York.

Amongst the most important aqueducts erected since the fall of the Roman empire may be cited the aqueduct of Spoleto, said, though, without reason, to have been built by Theodoric the Goth. It is however unquestionably of great antiquity; and perhaps it merits more attention than it hitherto has received, if it were only for the sake of correcting the errors printed in all works upon architecture with respect to it. Thus, in all those works, the height of the Spoleto aqueduct is said to be not less than 420 feet; but from recent measurements it would appear that the real height does not exceed, even if it attain, 240 feet. There is a remarkable aqueduct of the Renaissance period near Pavia; and at Caserta is a very lofty one, before mentioned as having been constructed by Vanvitelli: the latter aqueduct is about 2000 feet long and 200 feet high in the deepest part of the valley. At Lisbon there is an aqueduct, erected by Manoel da Maya, a Portuguese engineer, about 1738, of about 2600 feet in length and 231 feet in height; and about the year 1680 Vauban and Lahire had commenced the gigantic ruin which was intended to have carried the Eure to Versailles. This work was designed to have been of a total length of 3¼ miles nearly, and of a height of 234 feet. The aqueduct of Montpellier is about 2300 feet long and 92 feet high, in round numbers; whilst [the Roquefavour aqueduct, lately erected near Marseille, is 1312 feet long by not less than 282 feet in height. In England there are some large canal aqueducts, such as the Chirk and Pont y Cyssylte bridges, of cast iron, erected by Telford, and the Lune aqueduct, erected by Rennie; and of late years some remarkable works of the same description have been erected in France and in Italy, either for the canal or the irrigation works of those countries; but all these works sink into insignificance when compared with the aqueducts recently erected by the engineers connected with the Irrigation departments of our Indian empire. The great Solani aqueduct, upon the Ganges canal, is, for instance, of about 1050 feet in length, with an average height of 51 feet; but as the area of the water-way in the Solani aqueduct is as nearly as may be 80 times as much as that of the aqueduct of the Pont du Gard, it would be impossible to draw anything like a comparison between the two.

It may be necessary to add, that English engineers have almost entirely abandoned the use of aqueducts for town supplies, and that they have substituted for those costly monuments the simpler system of laying reversed syphons in the valleys through which they have to carry a water supply. In the cases of the Liverpool, Manchester, and Glasgow water-works, some remarkable illustrations of this practice may be observed, which will be noticed hereafter under the head SYPHON, REVERSED.

A'QUILA (the Eagle), a constellation situated above, so as to rest on, Capricornus and Aquarius. It may be readily found by means of the head of Draco and the bright star α Lyræ, since a line passes between β and γ Draconis, and through α Lyræ, passes through a bright star of the first magnitude, α Aquilæ, cutting also two stars of the third magnitude, β and γ, situated directly above and below α. This constellation is on the meridian at 8 o'clock P.M. in the middle of September, at about 40° of elevation. The following is an analysis of the number of stars visible to the naked eye in this constellation, arranged in the order of their respective magnitudes:—

Magnitude.	Number of Stars.
1·5	1
3	3
3·5	4
4·	2
4·5	1
5	10
5·5	12
6·	28
Total number	61

The stars down to the 4th magnitude inclusive are thus designated:—

Character.	No. in Catalogue of Flamsteed.	No. in Catalogue of British Association.	Magnitude.
ϵ	13	6487	3·5
λ	16	6526	3
ζ	17	6528	3
δ	30	6646	3·5
κ	39	6713	4
γ	50	6772	3
α	53	6802	1·5
η	55	6811	4
β	60	6833	3·5
θ	65	6934	3·5

In the Greek mythology, this constellation represents the eagle of Jupiter. According to some, it is the bird which was the tormentor of Prometheus. M. Dupuis conjectures, but with very little probability, that the name was given when Aquila was near the summer solstice, and that the bird of highest flight was chosen to express the greatest elevation of the sun.

The constellation Antinous is usually considered as a part of Aquila, and is treated as such in catalogues. It is represented as a boy in the grasp of the eagle, and its principal stars are η, θ, ι, κ, and λ, in the above catalogue. It is said to have been placed in the heavens by the order of the Emperor Hadrian, in memory of a favourite of that name, who is generally supposed to have perished in the Nile, A.D. 131. Others have supposed it to refer to the fabulous history of Ganymede, who was carried to heaven by the eagle of Jupiter; but this is rendered unlikely by the silence of Ptolemy, who, though he speaks of the group of stars in question, does not call them the constellation Antinous, but simply "unformed stars, among which is Antinous." Had the two figures originally contained any reference to the mythology above alluded to, it is most probable that the constellation would have been regularly distinguished long before the time of Ptolemy.

ARA (the Altar), a southern constellation, not visible in our latitude. It is situated near Lupus, above Pavo and Triangulum Australe, in such manner that the Centaur appears to be placing the wolf upon the altar. One mythological account explains it as the altar upon which Chiron sacrificed a wolf; another, as an altar constructed by Vulcan, upon which the gods swore fidelity to each other during the war against the Titans.

The following is a classified enumeration of the stars visible to the naked eye in this constellation:—

Magnitude.	Number of Stars.
3	3
3·5	1
4	3
5·5	4
6	48
Total number of stars	59

Subjoined are the designations of the principal stars:—

Character.	No. in Catalogue of Lacaille.	No. in Catalogue of British Association.	Magnitude.

ARABESQUE. This term is applied to a species of ornament, or mode of enrichment on flat surfaces, employed in works of architecture principally; though more commonly applied to painted ornament, the term is also applied to mosaics and to sculpture in low relief. The name is intended to mean simply "in the Arabian manner," and is a French form of that expression. The mode of enrichment which it refers to, was practised in the decoration of their structures by the Moors, Saracens, or Arabians of Spain, and from them particularly the species of ornament to which it belongs was so designated: the Alhambra affords almost endless examples of this description of Arabian ornament. As far as the Mohammedan conquerors of Spain were concerned, they appear to have borrowed the idea from the hieroglyphical enrichments of the monuments of Egypt. The dogmas of their religious code, however, forbidding the representation of animals, in order to avoid the very semblance of idolatry, they employed plants and trees in a similar manner, and with stalks, stems, tendrils, foliage, flowers, and fruit, produced an endless variety of forms and combinations, with which they painted and sculptured the surfaces of their buildings. Hence fanciful combinations of natural objects to form the continuous ornament of a flat surface came to be called Arabesque, though they differed so widely from the Arabian or Mohammedan compositions as to be filled with representations of animals of every variety, and with combinations of plants and animals, as well as combinations of animal forms almost equally discordant with nature. The name, indeed, has become so general as to be applied to the fanciful enrichments found on the walls in the ruins of Herculaneum and Pompeii, as well as to others of the same and earlier date, which were formed and forgotten long before the sons of Ishmael learned to draw.

Among the ancients, this style of ornament was most practised by the Etruscans, who largely introduced it in wall-paintings, vases, mirrors, &c.; indeed, it seems to have been singularly congenial to their turn of mind. (Muller, 'Etrusker,' ii.; Inghirami, 'Monumenti Etruschi;' Agincourt, &c.) It was from the frequent recurrence of these extravaganza decorations in the Etruscan grottoes, that what are now more generally called Arabesques used to be commonly styled Grotesques. Among the bizarre decorations of the Etruscans oriental forms often occur, which were no doubt obtained in the course of their commercial intercourse with the East. Among the Romans a taste for fantastic combinations was very prevalent in the days of Vitruvius and Pliny, both of whom strongly condemn it. In all, the object seems to have been to produce a cheerful fanciful effect. Sometimes the arabesques on the walls of Roman houses were made to serve as frames of larger pictures.

The most celebrated arabesques of modern times are those with which Raffaelle ornamented the piers and pilasters of the arcaded gallery of the palace of the Vatican, which bears his name. As Hittorff has pointed out, Raffaelle most probably received his first impression of the value of arabesques for the decoration of palatial apartments from those on the walls of the newly excavated Baths of Titus. The later discoveries in Pompeii and Herculaneum were of course unknown to Raffaelle and his scholars. Although the gallery of the Vatican, or rather the three galleries, for it is in three lengths, are always distinguished as Raffaelle's Galleries ("le Loggie di Raffaelle"), because of the arabesques and of the illustrations of the Bible history in the ceilings, only one of the three sides exhibits the designs of the great artist himself. As mere decoration the effect is by no means satisfactory. Their variety and irregularity, and their entire want of harmony with the subjects of the scriptural paintings, have been justly objected to, and they certainly detract from the simplicity and grandeur of the architecture. In the Villa Madama, the arabesques of which were designed by Raffaelle subsequently to those of the Vatican, and executed by his scholars, Giulio Romano and Giovanni da Udine, the subjects are entirely mythological, and they are treated in the manner of the ancient wall-paintings. (Grüner, 'Fresco Decorations of Churches and Palaces in Italy, during the 15th and 16th Centuries.')

From the time of Raffaelle arabesque painting rapidly declined. It was revived in France under Louis XV., but in a very meretricious style. During the present century it has been a good deal practised among the Germans, and some of the most eminent painters, as Kaulbach and others, have attempted it with more or less success. The best examples are at Munich and Berlin. Kept within proper bounds, it may be made a very effective means of ornamenting buildings and public rooms, especially those to which it is desirable to impart a gay, lightsome, and festive character.

M. Hittorff, in his 'Essay on the Arabesques of the Ancients, as compared with those of Raffaelle and his School' (p. xvi.), prefixed to the work of Mr. Grüner, cited above, lays down the following as the principles which should guide the artist in producing works like these:—

"That immoderate multiplicity fatigues the eye; that excessive copiousness causes many objects to be condemned as useless; that unity of conception, proportion of parts, and symmetry in the principal decorations, are indispensable laws never to be neglected."

ARA'BII were, according to St. Augustin ('Hæres.' c. 83), a sect of Christians in Arabia, who believed the human soul to be mortal, and that it is dissolved by death together with the body, but will be restored to life at the resurrection. Mosheim (in 'Commentariis de Rebus Christianorum ante Constantinum Magnum,' ed. 1753, p. 718, et seq.) thinks that the materialism of Epicurus had some influence on the origin of this sect: but it is more likely that the prevailing opinion in those days of the materiality of the human soul occasioned their heretical inferences. The Arabii were confuted and converted by Origen in a synod held in Arabia, A.D. 246 (Mansi 'Collectio Conciliorum,' t. i. p. 789.

ARABIN. [GUM.]

ARABLE LAND, so called from the Latin word *arare* 'to plough, is that part of the land which is cultivated chiefly by means of the plough.

Land in general is divided into arable, grass land, wood land, common pasture, and waste. The first of these is by far the most important in agriculture. In this article we shall briefly explain the principles on which are founded the most improved methods of cultivating arable land, by which the natural produce of the soil is greatly increased, and many productions are obtained in perfection which are foreign to the soil and climate.

1. We shall, first, consider the nature and properties of various soils.
2. The best modes of preparing and improving the natural soil, so as to increase its produce.
3. The most advantageous succession of crops, so as to obtain the greatest returns, with the least diminution of fertility.

Of soils.—When the surface of the earth is penetrated, we generally find that the appearance, texture, and colour vary at different depths. There is a layer of earth nearest the surface, of greater or less thickness, which covers the more solid and uniform materials which lie below it. This may be particularly observed wherever there are natural or artificial excavations or pits. A distinct line, nearly parallel to the surface, generally marks the depth of the upper soil, and separates it from the sub-soil. The soil is more or less composed of minute parts of various kinds of earth, mixed with animal and vegetable substances, in different states of decomposition; and to these, in a great measure, it owes its colour, which is generally darker than that of the subsoil. Except where iron, peat, coal, or slate abounds in the soil, a dark colour is an indication of corresponding fertility. The rich soil of gardens, long cultivated and highly manured, is nearly black. As the soil is the bed in which all vegetable productions are to be reared, and in which they are to find their proper nourishment, its texture and composition become objects of great importance to the cultivator; and, without a competent knowledge of these, no practical rules can be laid down or depended upon.

All soils are composed of earths,* metallic oxides, saline substances, vegetable and animal matter, and water. The earths are chiefly clay, or alumina, sand or silica, and lime.

Magnesia, barytes, and other earths, are occasionally met with, but in so few instances that they may be omitted in the list.

Of the metals, the most abundant is iron in the state of peroxide. The other metals are rarely found near the surface.

Saline substances form a small part of the soil, but an important one.

Potash exists in almost every vegetable, soda in a few, and ammonia is produced by the decomposition of almost all kinds of vegetable and animal matters, but it is very liable to waste, owing to its volatile nature and the extreme solubility of almost all its compounds.

Vegetable acids are more or less fully developed in all such decaying vegetable matters as exist in the soil. And in combination with some base, as lime or potash, they form part of the food which the roots of plants absorb.

The mineral acids are found united with earths and alkalies, in the state of neutral compounds.

These saline substances have a powerful effect on vegetation, and a knowledge of their proportions in the soil and of their various qualities, is indispensable if we would attempt to modify or correct their action by the addition of other substances for which they have an affinity.

Water, in a state of combination, or of mere mechanical diffusion, is essential to the growth of all plants: without it and atmospheric air, there is no life either animal or vegetable.

Of the Earths.—Clay or alumina, so called because it is obtained in its purest state from alum, in which it is combined with sulphuric acid,† is the basis of all strong and heavy soils. When it is minutely divided, it is easily suspended in water; when dried slowly and stirred while drying, it becomes a fine powder soft to the feel, and when kneaded with water, a tough ductile mass easily moulded into vessels which retain liquids. This property, of being comparatively impervious to water, gives the specific character to clay as an ingredient of the soil. In a pure and unmixed state it is barren. When clay is heated to a great degree, it parts with the water combined with it; it is then said to be baked, as we see in bricks. It is no longer diffusible in water, and differs little from silica or sand in its effects on the soil.

Silica, or the earth of flint, suffers no change in water. It consists of crystals, or fragments, of very hard stone, forming *gravel* or *sand*

* We retain the old division, although the earths have been ascertained to be oxides of peculiar metals; but as they are never found in the soil in their metallic state, the results and reasonings are not affected by this circumstance.

† Sulphuric acid, commonly called oil of vitriol, is composed of sulphur and *oxygen* which is about one-fifth part of the atmosphere.

according to their size; and the finest siliceous sand, when examined with a magnifying glass, has the appearance of irregular fragments of stone without any cohesion between them.

Siliceous sand holds water in its interstices by simple cohesive attraction in proportion to its fineness. It heats and cools rapidly, letting the water pass through it readily, either by filtration or evaporation. Its use in the soil is to keep it open, to let the air and water, as well as those other substances on which the growth of plants depends, circulate through it. Unmixed, it dries so rapidly that no vegetation can continue in it, unless a constant supply of moisture be given by irrigation. A small portion of clay will much improve light sands; it takes a large quantity of sand to correct the tenacity of clay.

Lime in its pure state is familiar to every one as the basis of the mortar used in building. It is produced by burning marble, chalk, limestone, or shells, in a great heat. In the stones which are formed principally of lime, it is combined generally with carbonic acid, which separates from it by the operation of burning, in the form of an air or gas, hence called *fixed air*, from its being thus *fixed* in a stone. These stones, of various degrees of hardness, are now all classed under the name of carbonates of lime.

Lime unites readily with water, which it also absorbs from the atmosphere. It then becomes *slaked*. By uniting with carbonic acid, it returns to its former state of carbonate; with this difference, that, unless much water be present, it remains a fine impalpable powder. Pure lime is soluble in water, though sparingly; a pint of water cannot dissolve more than about twenty grains: the carbonate is not soluble in simple water; though in water containing carbonic acid, it readily dissolves. Carbonate of lime has a powerful effect on the fertility of a soil, and no soil is very productive without it. It is consequently used extensively as an improver of the soil, otherwise called a *manure;* but its use in this respect, and the mode in which it acts, will be given in the articles MANURE and LIME.

Carbonate of lime, as an earth, is neither so tenacious as clay, nor so loose as sand. In proportion to the fineness of its particles it approaches to the one or the other, and when the parts are large and hard it takes the name of limestone gravel. Its distinguishing feature is its solubility in acids, which it neutralises, depriving them of their noxious qualities in the soil.

A proper mixture of these three earths, in a due state of mechanical division, forms a soil well fitted to the growth of every species of plants, especially those which are cultivated for food; and nothing more is required than a proper climate as to heat, a proper degree of moisture, and sufficient nourishment, to make all the plants generally cultivated thrive most luxuriantly in such a mixture, which is usually called a loam.

But there are some soils, which, besides a proper mechanical texture and mixture of earths, contain a large proportion of a natural manure which renders them extremely fertile. This is a substance produced by the slow decay of animal and vegetable matter. It can be separated from the other parts of the soil, and has been accurately analysed and described by many of the most experienced chemists, particularly by Fourcroy, Davy, Chaptal, and Theodore de Saussure. (See 'Recherches Chimiques sur la Vegetation,' Paris, 8vo, 1804.) This substance has been called *vegetable mould;* but, as this is not a very distinct term, we shall, after Thaer and other eminent writers on agriculture, adopt the name of *humus* when speaking of it. Humus is a dark, unctuous, friable substance, nearly uniform in its appearance. It is a compound of oxygen, hydrogen, carbon, and nitrogen, which along with certain mineral ingredients. are the elements of all animal and vegetable substances. It is the result of the slow decomposition of organic matter in the earth, and is found in the greatest abundance in rich garden mould, or old neglected dunghills. It varies somewhat in its qualities and composition, according to the substances from which it has been formed and the circumstances attending their decay. By bringing fresh portions of soil to the surface and permitting the access of air to it, this half-decayed vegetable matter is made to undergo still further changes resulting in carbonic acid and other substances in a form adapted to the nourishment of the growing plant. Hence we see the great importance of frequently stirring the surface of the earth between cabbages and other vegetables.

We can now readily understand the great importance of humus, and of those rich manures which are readily converted into it when not immediately absorbed by plants. But this vegetable ingredient of the soil has still another property, highly important to fertility: it renders stiff clays porous, and consolidates loose sands. It does so more than lime, or any other earth. Hence a soil with a considerable proportion of humus is much more fertile than the quantity of other substances in its composition would lead one to expect, as we shall see when we come to the analysis of soils of known fertility; and we see the great advantage of animal and vegetable manures, not only as nourishment to vegetables, but as mechanical improvers of the texture of soils.

The greatest enemy of humus is stagnant water; it renders it acid and astringent, as we see in peat; and soils abounding with vegetable matters, from which water is not properly drained, become *sour*, as is very justly said, and produce only rushes and other useless and unpalatable plants. The remedy is simple and obvious; drain well, and neutralise the acids with lime; by these means abundant fertility will be restored.

In very light soils humus is seldom found in any quantity, being too much exposed to the air and rapidly decomposed; the extract is washed through them by the waters, and as they waste manure rapidly, they are called *hungry*. Such soils are very unprofitable until they are improved and consolidated by clay or marl, which makes them retain the moisture.

With calcareous earths humus acts well, provided they are pulverised and of sufficient depth. Some chalky soils are rendered very fertile by judicious culture and manuring.

In order to ascertain the probable fertility of a soil, it is very useful to analyse it and find out the proportion of its component parts. To do this with great accuracy requires the knowledge of an experienced chemist; but certain steps in the process of analysis may be easily taken by any person possessed of an accurate balance and weights, and a little muriatic acid. For this purpose, some of the soil, taken at different depths, not too near the surface (from four to eight inches, if the soil is uniform in appearance), is dried in the sun till it pulverises in the hand, and feels quite dry: the small stones and roots are taken out, but not minute fibres. A convenient portion of this is accurately weighed: it is then heated in a porcelain-cup, over a lamp or clear fire, and stirred till a chip or straw put in it turns brown. It is then set to cool, and weighed; the loss of weight is the water, which it is of importance to notice. Some soils, to appearance quite dry, contain a large proportion of water; others, scarcely any. It is then pulverised and sifted, which separates the fibres and coarser parts. The remainder, again weighed, is stirred in four or five times its weight of pure water; after standing a few minutes to settle, the water is poured off, and it contains most of the humus and soluble substances. The humus is obtained by filtration, well-dried over the lamp, and weighed. The soluble substances are obtained by evaporating the water; but, unless there is a decidedly saline taste, this may be neglected. The humus may be further examined by heating it red hot in a crucible and stirring it with a piece of the stem of a tobacco-pipe, when the vegetable part will be consumed, and the earths remain behind; thus the exact quantity of pure vegetable humus is found. Some muriatic acid, diluted with five times its weight of water, is added to the deposit left after pouring off the water containing the humus and soluble matter: the whole is agitated, and more acid added gradually, as long as effervescence takes place, and until the mixture remains decidedly acid, which indicates that all the calcareous earth is dissolved. Should there be a great proportion of this, the whole may be boiled, adding muriatic acid gradually, till all effervescence ceases; what remains, after washing it well, is siliceous and argillaceous earth. These are separated by agitation, allowing the siliceous part to settle, which it does in a few seconds. The alumina is poured off with the water, filtrated, heated over the lamp, and weighed,—the same with the siliceous sand. The loss of weight is calcareous earth. In this manner, but with greater care and more accurate tests, various soils of known fertility have been analysed, of which we will give a few examples.

A very rich soil near Drayton, Middlesex, examined by Davy, consisted of $\frac{3}{5}$ of siliceous sand and $\frac{2}{5}$ of impalpable powder, which analysed, was found to be composed of

	Parts.
Carbonate of lime	28
Siliceous earth	32
Alumina	29
Animal and vegetable matter	11
	100

This is a rich sandy loam, probably long and highly manured, fit for any kind of produce, and, if deep, admirably fitted for fruit trees.

Another good turnip soil, also examined by Davy, consisted of eight parts of coarse siliceous sand, and one of fine earth, which, being analysed, consisted of—

	Parts.
Carbonate of lime	63
Silica	15
Alumina	11
Oxide of iron	3
Vegetable and saline matter	5
Water	3
	100

This is a very light sandy soil, and owes its fertility to the fine division of the carbonate of lime and the vegetable and saline matter. It may probably have been limed or marled at some time or other.

The best loam in France, according to Mr. Tillet, consists of

	Parts.
Fine siliceous sand	21
Coarse ditto	25
Carbonate of lime	37·5
Alumina	16·5
	100

A loam at Chamart, highly prized by gardeners about Paris, as the basis of their artificial soils, consists of

	Parts.
Argillaceous sand	57
Finely divided clay	33
Siliceous sand	7·4
Carbonate of lime, coarse	1
Ditto, fine	0·6
Woody fibre	0·5
Humus and soluble matter	0·5
	100

The argillaceous sand is composed of fragments of soft stone, which retain moisture, and do not bind hard; the small proportion of humus is of no consequence where manure is to be had in any quantity.

A very rich heath or bog-earth found at Meudon, and in great request for flowers and in composts, consists of

	Parts.
Gritty siliceous sand	62
Vegetable fibres partly decomposed	20
Humus	16
Carbonate of lime	0·8
Soluble matter	1·2
	100

This soil, like our bog earth, would be very unfit for the growth of corn, but, from the quantity of vegetable matter, is highly useful in composts and artificial soils. Mixed with lime, it would make an excellent top-dressing for moist clay soils.

The above analyses give but a rough idea of the composition of a soil; in fact they for the most part indicate those causes of fertility or barrenness in soils, which reside in their varying texture or in their relations to water, rather than those which act by the abundance or deficiency of those substances which are the food of plants. An analysis which shall fully explain the fertility of a soil, must tell us not only the quantity and condition of the sand, and clay, and lime, and humus of a soil, but also the quantities of potash, soda, magnesia, phosphoric acid, sulphuric acid, chlorine, soluble silicates, and ammonia present in it. It is the presence, whether of humus or any other ingredient which shall, by the operation of atmospheric solvents, gradually yield to the growing plants such substances as these, which determines the fertility or infertility of a soil. And since the publication of Liebig's writings on Agricultural Chemistry, the importance once attributed to the presence of mere humus in the soil as the true index of its fertility, has disappeared. It is now known that the decaying vegetable matter of a soil is of service, not only as itself yielding, by its gradual destruction, food for plants, but also, and even chiefly, by its action as a ferment on the stores of food laid up in the clays and purely mineral portions of the soil, as well as by the facilities of access given, by its mixture with these mineral matters, to the air and water of the atmosphere, which by their disintegrating and decomposing operations, let loose from these stores much that is naturally locked up and useless.

Of course, the depth of the soil and the nature of the subsoil greatly affect the value of land. However rich it may be, if there is only a thin layer of good soil over a sharp gravel or a wet clay, it can never be very productive: in the first case, it will be parched in dry weather; and in the latter, converted into mud by every continued rain. If the subsoil be loam or chalk, six inches of good soil will be sufficient. With a foot of good soil, the subsoil is of little consequence, provided it be dry, and the water can find a ready outlet. The best alluvial soils are generally deep; the chalky, shallow. It is of importance to observe, that not only does fertility depend on the presence in the soil of abundant food for the growth of plants, but also on there being sufficient freedom of passage through it for the rain-water, which, as it traverses the soil, dissolves out this food, and takes it by the roots of plants, thus giving them an opportunity of absorbing it. A soil in which water is stagnant, or through which it cannot pass, is necessarily barren; the plants which would grow upon it starve, because there can be no circulation through it of dissolved food, no opportunity therefore of supplying the roots with fresh supplies of nourishment. It is to its thus providing for the circulation through the soil of food for plants, that the fertilising influence of land drainage is chiefly due; but the reader must be referred to the article DRAINAGE for a fuller explanation of its operation.

The exposure, with respect to the sun, and the declivity of the ground, are very important circumstances in the value of land; they are indeed equivalent to an actual difference in the climate. A gentle declivity towards the south, and a shelter against cold winds, may make as great a difference as several degrees of latitude; and in comparing the value of similar lands in different climates, the average heat and moisture in each must be accurately known. A soil very fertile in the south of Europe may be very unproductive in England; and a light soil of some value in the west of Scotland, might be absolutely barren in Italy or Spain.

Of the Cultivation of the Soil.—The better the soil, the less cultivation it requires to produce tolerable crops; hence, where the land is very rich, we find in general a slovenly culture; where the ground is less productive, more labour and skill are applied to compensate for the want of natural fertility. The simplest cultivation is that of the spade, the hoe, and the rake,—and on a small scale it is the best; but spade husbandry cannot be carried to a great extent without employing more hands than can be spared from other occupations. The plough, drawn by oxen or horses, is the chief instrument of tillage, and has been so in all ages and nations of which we have any records. Its general form is familiar to every one, and requires no minute description. The various kinds of ploughs in use at different times, and the improvements which have been made, and are attempted, daily, will be noticed in a separate article. [PLOUGH.] Suffice it to say at present, that a plough should as much as possible imitate the work done with a spade. It should cut a slice from the land by its coulter (*a*) vertically, and by the share (*b*) horizontally lift it up, and turn it quite over by means of the mould-board (*c*); and the art of the plough-

man consists in doing this perfectly, and with such a depth and width as suit the soil and the intended purpose. In rich mellow soils a ploughed field should differ little from a garden dug with the spade. In tenacious soils, the slice will be continued without breaking, especially if bound by the fibres and roots of plants; the whole surface will be turned over, and the roots exposed to the air: it is of great consequence that each slice be of the same width and thickness, and the sides of it perfectly straight and parallel. The plane of the coulter must be perfectly vertical, and that of the share horizontal, in order that the bottom of the furrow may be level, without hollows or *baulks*, which are irregularities produced by the rising or sinking of the plough, or inclining it to either side. The ancients were very particular in this respect, and recommended sounding the earth with a sharp stake, to ascertain whether the ploughman had done his duty. There are various modes of ploughing land, either quite flat, or in *lands* or stitches, as they are called in England, and, in Scotland *riggs*, that is in portions of greater or less width, with a double furrow between them—somewhat like beds in a garden. Sometimes two furrow slices are set up against each other, which is called ridging or *bouting;* the land then is entirely laid in high ridges and deep furrows, by which it is more exposed to the influence of the atmosphere and kept drier; this is generally done before winter, especially in stiff wet soils. Sometimes two or more ridges are made on each side, forming narrow stitches. When the ground is to be ploughed without being laid in lands or stitches, and all the ridges inclined one way, the mould-board of the plough is shifted at each turn from one side to the other. The plough which admits of this is called a *turn wrest plough,* and is in general use in Kent, and in many parts of the Continent, where the subsoil is dry and the land not too moist. In most other situations the ground is laid in *lands,* and the mould-board of the plough is fixed on the right side. When grass land or stubble is ploughed, care must be taken to bury the grass and weeds completely, and the slice cut off by the plough must be turned over entirely, which is best done by making the width of the furrow greater than the depth. When the grass and weeds are rotten, and the ground is ploughed to pulverise it, a narrow deep furrow is best; the earth ploughed up is laid against the side of the preceding ridge, which forms a small furrow between the tops of the ridges, well adapted for the seed to lodge in and to be readily covered with the harrows.

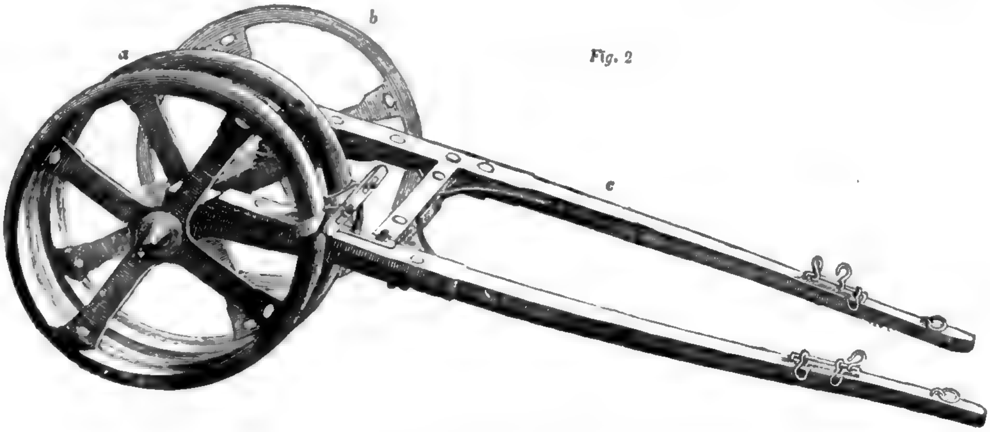
Nothing has divided both practical and theoretical agriculturists more than the question whether the land should be ploughed deep or shallow; but a very slight attention to the purposes for which land is ploughed, and to the nature of the soil, will reconcile these apparently contradictory opinions. A deep, rich, and stiff soil can never be moved too much nor too deep: deep ploughing brings up rich earth, admits the air and water readily, and gives room for the roots to shoot, whilst the rich compact soil affords moisture and nourishment. Wherever trees are to be planted, the ground should be stirred as deep as possible, even in a poor soil: for grass and corn, however, this is not always prudent; for though their roots traverse a considerable depth of soil, yet the principal portion of them terminates in the surface soil; and in addition to this there is, in reference to some plants, an advantage in preserving a firm texture of subsoil.

Whenever the soil below a certain depth is of an inferior quality, there can be no use in bringing it up, until by tillage and land draining it has been improved; and where the soil is light and porous, the bottom had, as we have said, for many plants better not be broken. In such soils, indeed, it is usual rather to attempt the artificial consolidation of the land than to loosen it; and to this end the *land-presser* or *press-drill* is used. This instrument consists of two very heavy cast-iron wheels, *a a, fig.* 2, with angular edges, set on a common axle, at a distance from each other equal to the width of the furrows, and a lighter wheel, *b*, to keep the instrument vertical.

It is drawn by a horse immediately after the plough; pressing two furrows at once, and going twice over each furrow, or if it follows two ploughs, once only. It leaves the land in regular drills, and the seed sown by hand falls into the bottom of the drills, and is covered by the harrows. When the plants come up they appear in regular parallel rows.

The great object in ploughing land is to divide it, expose every part

Fig. 2



Press Drill or Land Presser.

of it to the influence of the elements, and destroy every plant or weed but those which are sown in it. To do this perfectly requires several ploughings, with certain intervals, and during that time no crop can be upon the land. This is the real use of fallows, and not, as was once supposed, to allow the land to rest; on the contrary, it ought then to have the least repose.

Where the soil is good, with a porous subsoil, the greatest care should be taken not to go too deep; but where the subsoil is compact and impervious to water, but not wet for want of outlet or draining, it is useful to stir the soil to a great depth, but without bringing it to the surface, which may be done by a plough without a mould-board, following a common plough in the same furrow. This is an excellent auxiliary to draining, at the same time keeping a reservoir of moisture, which in dry weather ascends in vapours through the soil and refreshes the roots.

The mode in which the soil is prepared most perfectly for the reception of the seed, is best shown by following the usual operations on fallows. After the harvest, the plough is set to work, and the stubble ploughed in. The winter's frost and snow mellow it, while the stubble and weeds rot below. In spring, as soon as the weather permits, it is ploughed again, the first ridges being turned over as they were before: this completes the decomposition of the roots and weeds. It is then stirred with harrows or other instruments, which tear up the roots which remained, and some of these not being easily destroyed, are carefully gathered and burnt, or put in a heap to ferment and rot, a portion of quicklime being added. Another ploughing and stirring follows, at some interval, till the whole ground is mellow, pulverised, and free from weeds; manure is put on, if required, and immediately spread and ploughed in; the land is then prepared for the seed.

This has been the method universally followed by all industrious husbandmen from the oldest times. The Romans had names for each of the ploughings: the first was *frangere,* the next *vertere,* the third *refringere,* and the fourth *revertere;* more ploughings were often given, and in modern agriculture the direction of the third ploughing is sometimes changed across the old furrows, at a right, or acute angle, as Virgil recommends ('Georgica,' i. 98), by which the earth is still better divided and mixed. The best modern practice does, however, now so far depart from the ancient model, that a greater portion of cultivation is generally effected before winter. The practice of autumn cultivation of stubbles has greatly increased of late years. A thorough cleansing of stubble land, and even the manuring of it previous to the last ploughing before winter, is now often accomplished. The soil is then left in such a state, that it only needs a stirring and harrowing in the spring, to be ready for most of the spring-sown crops.

Various instruments have been invented to stir the earth and mix it, without so often using the plough, and also to loosen and separate roots and weeds; of these the principal are, the cultivator or scarifier, which enters but a few inches into the ground, and moves a great surface by means of tines, or iron teeth of various constructions. The whole instrument is made of iron: *a a,* the frame; *b,* the beam; *c c,* rods by which it is drawn, the horses being attached by a hook at the point *d; e e,* the handles; *f f f,* different-shaped shares and tines to be used according to the state of the soil; *g g g,* contrivances by which the teeth are fixed to the frame at any required distance from each other, and lengthened or shortened; *h h h,* three wheels to regulate the depth of the ground moved. By raising the beam and fixing it higher or lower on the piece (*i*), by means of an iron pin passed through the different holes, the whole instrument is raised or depressed in the ground. *Fig.* 3 represents a simple form of this tool. Coleman, Bentall, Ransome, and many other manufacturers, have better and more efficient implements of the kind.

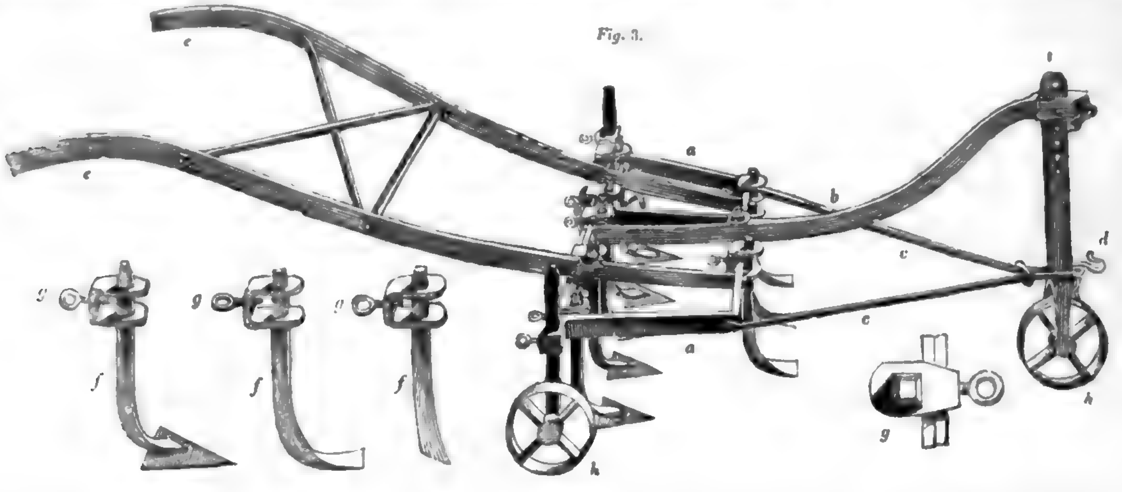
This instrument divides the soil, but does not turn it over; it is well calculated to destroy roots and weeds, and let in the air; but, evidently, is only adapted to tolerably loose and mellow soils, where there are no large stones.

An ingenious harrow or cultivator has been invented by Finlayson, which rakes the weeds out of the ground, and throws them on the surface without clogging the instrument; it is excellent in light soils (*fig.* 4).

When the soil turned up by the plough is in large hard lumps, a roller, smooth, ribbed, or toothed, is drawn over the land to break the clods. The need of this is greatly increased where very stiff soils have been ploughed when too wet, and the ridges have dried, and been ploughed again in dry weather. Deep wet clay soils should be carefully watched, to know when is the proper time to plough them; nothing pulverises them like frost, and if they are kept from wet by careful draining and numerous water furrows in autumn, they will be loose and friable in spring; they had better not be touched than worked when too wet. On light soils the plain roller is used to advantage to produce firmness, without which the plough cannot so well turn the ground over completely, but merely pushes it to the right and left.

The great expense of teams for the plough has led to expedients and inventions to lessen the labour; but, in general, a more imperfect cultivation has resulted from it. Columella mentions one Celsus, whom he blames because, to 'save the expense of a stronger team, he only

Fig. 3.



Scarifier.

scratched the ground with small shares and toothed instruments (*exiguis vomeribus et dentalibus*);' and a modern agriculturist of some note has revived the practice of Celsus. General Beatson, who had been in India and had seen the simple instruments used there by the natives, substituted for the plough and cultivators in common use, various light instruments, of which he published an account. He recommended stirring the soil only a few inches deep, except occasionally; and, by means of burnt clay, which he used in great abundance, he produced a succession of good crops: but he had too high an opinion of the fertilising qualities of burnt clay, which made him undervalue animal and vegetable manure; and although he may have improved the texture of his heavy soil by the burnt clay, which is

insoluble and absorbent, he will find out, like the followers of Tull, that manures which contain the whole food of plants can alone maintain fertility.

The influence of the atmosphere on the soil, and the increased fertility produced by pulverising and stirring heavy lands, has led to the notion adopted by Jethro Tull, that labour might entirely supersede the necessity of manure: hence the origin of the horse-hoeing husbandry, which at one time was so highly thought of as to be called, by way of distinction, the *new* husbandry. Fallows and manuring were both discarded as unnecessary, the seed was sown in rows with wide intervals, which were continually kept worked and stirred. At first the result was highly satisfactory; all the available food of plants, by exposure to the air, was brought into use, and taken up by the plants, which throve well as long as the supply lasted; but in the end it was exhausted; and the warmest admirers and supporters of Tull's system, Du Hamel and De Châteauvieux, besides many others, found to their cost, in practice, that pulverising alone will not restore fertility. The system of drilling and horse-hoeing, when united with judicious manuring, has, however, been found a great improvement in agriculture. The most distinguished follower of the school of Tull is the the Rev. S. Smith, of Lois Weedon, Northamptonshire, whose experience, now extending over eleven or twelve years, proves that on certain soils a properly timed and industrious tillage, gradually deepening the cultivated land, does maintain its fertility in an extraordinary manner, independently of any addition of fertilising matter in the form of manure. But for a further description of this subject, we must refer to the article TILLAGE.

In describing the various processes in general use in the cultivation of the soil, we have taken the year when the land is fallowed; because it is then that it receives the most perfect culture, which enables it to produce several crops afterwards with a much smaller quantity of labour. By such fallowing and proper manuring, the soil is fully restored to its highest degree of fertility. In light soils, which are generally poorer, turnips or other green crops are sown, on which sheep are penned, which by their manure still more enrich the soil; and it is only when this manure is ploughed in, that the land may be considered as possessing the full degree of fertility.

There are some soils which are so mixed with pebbles and stones, that instruments for their cultivation must be adapted to their texture. Some of these soils, abounding with chalk, are tolerably fertile, and the stones, when they are not so large as to impede the operations, are rather beneficial than otherwise. Theophrastus mentions a field which had been deprived of its fertility by the removal of the stones, and others have learned the same from experience. Pebbles prevent too great evaporation, shelter the young plants in exposed situations, and reflect the light and heat of the sun. The only inconvenience found from them in good soils is that they occupy the room of better earth, and wear out the instruments used, which in consequence are made stronger and blunter. When there is a crop to be mown with the scythe, the stones must be removed from the surface, but not otherwise, at least in light soils.

When the land has been duly prepared, the seed is sown. This is done sometimes before the last ploughing, but then the manure should have been ploughed in before; for, except in planting potatoes, which are not seed, but budded portions of an underground stem, the manure should always be deeper, and not in contact with the seed; indeed, the proper plan is to mix the manure thoroughly with the soil. When the seed is ploughed in, the furrow-slice should not be above two or three inches deep, and eight or nine wide; and it is only in particular soils that this mode is to be recommended. The most common method is, to sow the seed on the land after the last ploughing, and draw the harrows over to cover it. When the land has been well ploughed, and especially if the press-drill has followed the plough, the seed will mostly fall in the small furrows made by two adjoining ridges, and rise in regular rows. But by far the most perfect way is, to sow it at a regular depth, by means of a machine, and in rows at regular distances [DRILL], or to *dibble* it, which is an operation performed only in a few parts of England, especially in Suffolk, Essex, and Norfolk. A man makes small holes at the distance of four or six inches, and in rows nine to twelve inches asunder, with two rods about thirty inches long, one in each hand, having an oval ring for a handle at one end, and at the other an inverted cone three inches in the axis and an inch and a half diameter at the base, which he pushes and turns with his hands in the ground to prevent the earth adhering, and makes the holes rapidly going backwards along the furrows. Two or more children follow and drop three or four grains in each hole. A harrow is drawn over the ground, and fills the holes with loose earth. When the corn comes up it looks like a regular plantation.

The proper season for sowing each kind of grain, the choice of seed, and other particulars will be given under the names of the different seeds usually sown. As a general rule it may be observed, that the smaller the seed, the less it must be covered, and clover or grass seed are either very lightly harrowed in, or only pressed in with the roller.

Of the succession of crops or rotations.—It has been found by experience, that besides the general exhaustion produced by vegetation, especially by those plants which are allowed to ripen their seeds, each kind of crop has a specific effect on the soil, so that no care or manure can, as a general rule, make the same ground produce equal crops of the same kind of grain, for any length of time without the intervention of other crops. Whether this be owing to any peculiar nourishment necessary to each particular kind of plants, or because plants not indigenous degenerate in a foreign soil; the fact is certain with respect to most crops usually raised; the turnip and clover crops may be cited as instances. This points out the advantage of varying the crops, according as they are found to succeed best after each other. In general, all kinds of grain succeed best after a crop which has been cut before the seed has ripened, or the stem is dried up. Those plants which have a naked stem with few leaves thrive best after leguminous plants, which have more succulent stems and more leaves, and which bear their seeds in pods, as peas, beans, tares, or vetches; or after esculent roots, which strike deep into the ground, as carrots, parsnips, beet-roots, and turnips. From this circumstance, confirmed by universal experience, the different systems of rotation have had their origin, taking the nature of the soil into consideration.

The simplest rotation, and one which can only be adapted to the richest strong alluvial soils, is that of wheat and beans, alternately, and without any intermission. It is in use in some parts of Kent and Essex, and in a few places in Germany. The land is well prepared and manured for the beans, which are set or drilled in rows, so as to admit of horse-hoeing between, as in Tull's method, till the beans get to a considerable height; besides this, careful hand-hoeing and weeding are practised, by which the land is cleaned and stirred as in a regular fallow. The beans being cut, the ground is ploughed once, and the wheat sown. It is the practice in some places to scarify the land immediately after harvest, to cut up the stubble. It is done in Kent with a plough without a mould-board, and with a very broad share, hence called *broad-sharing*, but most usually by the scarifier mentioned before: the stubble and weeds, if any, are raked up and burned: this is an excellent practice. Another equally simple rotation, on very poor light land, is that of turnips and barley alternately, which is mentioned by Arthur Young as being in use in the county of Durham, with the simple variation of clover occasionally. The turnips are always fed off by sheep folded on them. Where winter food for the sheep is scarce, this rotation may answer, but otherwise cannot be very profitable.

The oldest rotation known, and which was almost universal in Europe, from the time of the Romans, wherever any regular system of agriculture prevailed, is the triennial rotation of fallow, winter corn, and summer or lent corn; that is, wheat or rye sown in autumn, and barley or oats sown in spring. This was called the three-field system; and on every farm, the arable land was divided into three parts, one of which was in fallow, one in winter corn, and one in summer corn. When properties were much intermixed and subdivided, the whole of a considerable tract was divided into three fields, and it was almost impossible for any individual to deviate from the established course; especially as a right frequently existed of pasturing all the sheep of the parish or district on the fallow field in summer, and on all the others after harvest. In England, this impediment was removed by the legislature passing Acts of enclosure; but it is still felt in many parts of the Continent. This rotation had its advantages, or it could never have been so long in use. Where a sufficient quantity of manure could be collected by means of cattle fed on pastures and commons in summer, and in the strawyard in winter, to give a regular dressing to the fallows every third year, good crops were produced, and the fertility kept up. The labour was very equally divided throughout the year; and such was the regularity of every operation, that a large quantity of land might be cultivated by a proprietor at a considerable distance, with only occasional inspection, without an overseer or bailiff, provided he had honest servants. But, when pastures came to be broken up, and converted into arable land, and cattle consequently diminished, the land could not be manured on every fallow; the crops suffered; less straw being grown, the quantity of manure was diminished, and the land became gradually less and less productive, till, from necessity, a portion was left uncultivated, and returned to natural and inferior pasture; this gave the idea of laying the land down regularly to grass by sowing seeds, and gradually introduced the alternate and convertible system of which we will take notice hereafter.

The apparent loss of a third part of the land by the fallows introduced various crops, which were supposed not to exhaust the soil, but rather to enrich it: of this kind, one of the first was clover, introduced by the Flemish; and afterwards turnips, which have been found of such importance in light soils and moist climates. By substituting turnips for an entire fallow, or, more properly, sowing them early on the regular fallow, and interposing the clover between the summer and winter corn, the highly improved Norfolk rotation has been obtained, namely, 1. Turnips, well manured; 2. Barley; 3. Clover; 4. Wheat. By this a sufficiency of food for sheep and cattle is obtained, without natural pastures, and the land, manured every fourth year at least, is kept in a regular state of progressive improvement. The advantages of this rotation have made it a condition in many leases of light land, under heavy penalties in case of deviation. The first and principal inconvenience found in it was the failure of the clover in most soils, if sown every fourth year; this obliged the farmer to have recourse to other less profitable crops, such as ray-grass, peas, or tares, which, in light lands, are not equal to broad clover as a preparation for wheat. Where the soil is firm and rich, and at the same time mellow, a rotation may be introduced, compounded of the first and last mentioned; that is, beans, wheat, turnips, barley, clover, wheat, making a rotation of six years. This can only be introduced with advantage where there are considerable pastures, and much cattle is kept to supply manure for the land *twice* in the rotation, namely, for the turnips and for the beans, and where the drill husbandry admits of hoeing and weeding thoroughly; but with these advantages, no course can be more profitable, as is found in those parts of Kent and Essex where marsh pastures are attached to the farms. If the soil is too heavy and wet for turnips, and they cannot well be drawn off nor fed on the land without injuring it, a clean fallow is substituted for the turnips, the other crops remaining the same; or cabbages, or mangold wurzel, are planted for the cattle, but seldom to a great extent. A long fallow from after harvest until the second spring, including two winters, prepares the land admirably for barley, so that it can be sown without any manure, which is reserved as a top-dressing for the young clover after the barley. This is a very excellent method. The clover or ray-grass will be more abundant, and the wheat after it will not be in danger of running to straw, or lodging, that is, falling down for want of a sufficient hold of the ground by the roots.

We may add here the following enumeration of existing rotations. The four years' course of crops which originated in Norfolk, is, as has been said, 1. Wheat; 2. Turnips; 3. Barley; 4. Clover.

When the too frequent repetition of clover or turnips induces disease, one half of the barley stubble is broken up for beans, and that half is put to mangold wurzel after the succeeding crop of wheat, so that this becomes an eight years' rotation, namely, 1. Wheat; 2. Turnips; 3. Barley; 4. Beans; 5. Wheat; 6. Mangold Wurzel; 7. Barley; 8. Clover.

Sometimes when turnips are all fed off on the land where they grow, the barley crop is too luxuriant and becomes laid, and the malting qualities of it cannot be good. In that case the four years' or Norfolk rotation, is modified by the introduction of a wheat crop between the turnips and barley, so that it becomes a five years' rotation, namely, 1. Wheat; 2. Turnips; 3. Wheat; 4. Barley; 5. Clover.

Where the land and climate are unfavourable to the adoption of so severe a rotation, the Norfolk course is modified by the extension of the clover over two years, thus, 1. Wheat; 2. Turnips; 3. Barley; 4. Clover and Grass; 5. Clover and Grass.

The East Lothian rotation, adapted to the rich soils of the lowlands in that county, lasts six years, thus, 1. Wheat; 2. Turnips; 3. Barley; 4. Clover and Grass; 5. Oats; 6. Potatoes and Beans.

And in the same county, where potatoes are more largely cultivated a seven years' rotation obtains, that crop being taken after the turnip crop, thus, 1. Wheat; 2. Turnips; 3. Potatoes; 4. Wheat; 5. Grass; 6. Oats; 7. Beans.

On the clay alluvial lands of Scotland, a bare fallow is taken in the first year, followed by, 2. Wheat; 3. Barley; 4. Clover and Grass; 5. Oats; 6. Beans; 7. Wheat.

We may add to these a fourth modification of the Norfolk course, recommended by Mr. Caird, for cases of light potato soils where the cultivation of potatoes is advisable, namely, 1. Wheat; 2. Clover; 3. Oats; 4. Turnips; 5. Potatoes.

These rotations are sufficient to give some idea of the principles on which they have been adopted. In Scotland they adhere less strictly to particular rotations, nor are the tenants in general so much tied down as in England; seasons and circumstances cause deviations, which are sometimes judicious and often unavoidable. It is best, however, to follow some regular course, and in the end it will be found most profitable. A very common rotation in Scotland is fallow, wheat, clover, or grass fed one, two, or three years, then oats, peas, or beans, and wheat again, if the land is clean and in good heart; for there is no rule better established, than that of never allowing the soil to be exhausted beyond a certain point where manure and tillage can readily recruit it. The greedy cultivator is sure to pay dearly in the end for every crop forced from the land unreasonably; but the means of remedying exhaustion of the land, both those which depend on the use of efficient implements of tillage, and those which depend on the application of manure, are so multiplied and extended since the days in which most of these systems of rotation originated, that there is not that need of them which once there was, and an energetic and liberal cultivator need not be deterred by the circumstance that it is out of its place in the rotation, from taking any crop from soil in fitting condition which it may be his interest to grow.

Without preventing the tenant from using his discretion as to the mode in which his farm is best cultivated, a proprietor may be sufficiently protected against wanton deterioration of the land, by insisting on a green crop or fallow intervening between every two crops of grain, and consuming all the fodder and roots on the farm. For this subject we must refer to the article Farm. A proprietor with skill and experience cultivating his own land, need only consider the state and quality of his fields, and what will most likely grow well in them: what is most in request, both for his own use and in the market; what will keep his men and cattle in most regular work, without confusion or hurry. If he allows his land to be impoverished for want of manure, or to run wild with weeds, for want of hoeing or fallowing, he has not the experience and judgment which are necessary for his pursuits.

The Flemish husbandry proceeds much on this principle: The greatest attention is paid to manuring and weeding. Much more manual labour is bestowed than with us, and the crops seem more certain, varied, and abundant. That it is not unprofitable we may conclude from the wealth of the peasants, the comfort of the labourers, and the sleek appearance of the cattle. From the very interesting account of Flemish agriculture in the work of Mr. van Aelbroek of Ghent, written in Flemish, translated into French, and published at Paris in 1830, we learn with what great care the soil is cultivated in Flanders. After ploughing into lands as we do, every intervening furrow is deepened and cleared with the spade, the earth being thrown over the bed sown. Liquid manure (which is sadly thrown away in this country), chiefly the urine of animals and drainings of dunghills, is carefully collected, and is carried on and distributed over the poor light soils, by means of water-carts, before sowing, and again when the crop is come up. By this means such lands are made to yield crops of rape seed, clover, lucern, flax, and corn equal in luxuriance to those on the richest soils. Fallows are rendered unnecessary by the careful destruction of weeds. In short, it is a garden culture on an extended scale. All the land is in tillage, except where rivers occasionally overflow, and render the meadows rich and profitable. The cattle are mostly kept in stables, and fed with green food cut and brought to them; by which means one acre of clover, lucern, or other artificial grass, will maintain five times as many beasts, or more, as an acre of the best pasture; but the great object is to increase manure, especially in a liquid state, which is carefully preserved in reservoirs, without loss or waste, till wanted for the land. This system is also followed in Switzerland, which, considering its soil and climate, is one of the best-cultivated countries in Europe.

We observed before, that the want of a sufficient supply of manure on the old three-field system led to the laying-down arable land to pasture for a time and then breaking it up again. This was first practised in a regular rotation in Holstein and Mecklenburg, and raised these countries rapidly amongst agricultural nations.

In Holstein, on moderately good soil, they adopt the following course: 1. Oats, on newly broken-up grass land. 2. A fallow to destroy grasses and weeds, and accelerate the decomposition of their roots. 3. Wheat with or without manure, according to the state of the land. 4. Beans, barley, or oats. 5. Wheat, manured, unless it has been done for the beans the year before. 6. Grass seeds pastured for three years or more, when the rotation begins again.

A Mecklenburg rotation, not unlike the Scotch, consists of, 1. Beans well manured, or potatoes. 2. Wheat or oats. 3. Barley or oats, unless sown the year before. 5. Peas or tares, *manured*. 6. Wheat. 7. White clover and grass seeds, which were sown among the wheat the year before, and are kept in pasture during the 8th and 9th years. There is no fallow, and in a moist climate it will be difficult to keep the land clean. It might, however, easily be introduced, as in the Holstein rotation.

Another rotation is, 1. Oats. 2. Beans well manured. 3. Wheat. 4. Tares manured. 5. Barley. 6. Clover and grass seeds mown for hay and green fodder. 7 and 8. ditto, fed. All these are excellent for a moderately good soil well managed. If the soil is very rich, the following is the most profitable of any: 1. Rape seed well manured. 2. Wheat. 3. Beans or potatoes manured and hoed. 4. Barley. 5. Clover. 6. Wheat. 7. Oats with white clover and grass seeds pastured two or three years. The principal object in this convertible system is to lay the land down in good heart, and as clear of weeds as possible: the grass will then be abundant, and continue good for several years. Liquid manure, carried upon it in spring, will so enrich it as to admit of making the crop into hay, or cutting it green for the cattle in the stables. In light soils, the tread of sheep and cattle is of great use; in heavy, wet soils, they would do harm. No wet land will bear this rotation.

We have now given a brief outline of the manner in which arable land may be cultivated and improved. If we should be asked, whether so much attention and labour upon land of a proper quality will be repaid by the value of the produce, after deducting the portion due to the landlord, or to the state? we shall answer, without any hesitation, in the affirmative, provided the cultivator is possessed of knowledge, judgment, and experience, and devotes all his time to the superintendence of his farm. The calculations on which this opinion is founded cannot be introduced here; some idea of them will be given in the article Farm. Agriculture is so healthy and so agreeable an occupation, that it can never be extremely profitable: the competition for land will always prevent this. The butcher and cattle-dealer will always, if successful, make far greater profits than the farmer; and a decent livelihood, with a moderate interest on the capital laid out, is the most that a farmer can expect, even with the greatest assiduity. If he neglects his business, and leaves it to others less interested in the result, he must be a loser. Gentlemen who cultivate for pleasure, and employ bailiffs, are fortunate if they get a moderate rent after paying expenses. For careless farmers, the simplest system alone can prevent great loss; and grass land may be profitable in the hands of a proprietor, who would probably be ruined if his land were all arable and in his own hands.

Our limits will not permit us to enter into the important subject of improvements,—nor into the question of great or small farms, as most beneficial to the community:—these and various other branches of the subject will be found under proper heads; such as Barren Land, Farm, Draining, Irrigation, Manure, Labour, Grass-land, Cattle, &c.; and for the peculiar cultivation of the various products of agriculture, see Wheat, Beans, Barley, Clover, Oats, Peas, &c. &c.

We shall only add the names of a few authors whose works may be studied and consulted with advantage, by all those who desire to have a competent knowledge of agriculture, either as a branch of general knowledge, or for the purpose of its practical application.

Of the Greek writers on husbandry we have hardly anything left, except in the collection of Cassianus Bassus, entitled 'Geoponika' (earth-labouring). This collection, in twenty books, was made at the command of the Emperor Constantinus Porphyrogennetus, and was chiefly compiled from Greek writers, whose names are given. We are not aware that there is any foreign translation of the 'Geoponika,' except the old German version of 'Herren,' first printed at Strasburg in 1545, 4to. The Latin writers, Cato, Varro, Virgil in his 'Georgics,' Columella, and Palladius, are well known: their works, especially the last two, will be found to contain many valuable remarks; and abridged translations of them, or extracts, would be very useful even to modern agriculturists. Of the above, the following have been translated by the Rev. T. Owen, rector of Upton Scudamore, Wilts: 1. 'The Three Books of M. Terentius Varro, concerning Agriculture.' London, 1800. 8vo. 2. 'The Fourteen Books of Palladius on Agriculture.' London, 1807. 8vo. The same author has also published 'Agricultural Pursuits, translated from the Greek.' London, 1805. 2 vols. 8vo. Of the earlier English writers, we shall only mention Fitzherbert, Blythe, Hartlib, and Weston. Afterwards came Evelyn, Tull, Hale, and the great oracle of modern husbandry, Arthur Young; with

Sir John Sinclair, to whom, as President of the Board of Agriculture, much useful information was communicated, which he industriously compiled. (Sinclair's 'Account of Systems of Husbandry,' &c., 2 vols. 8vo.) The Surveys and Reports on the agriculture of the different counties, prepared for the Board of Agriculture, are replete with useful information as to what is the actual practice; and among a multitude of agricultural publications, journals, and proceedings of societies, we may notice Loudon's 'Encyclopædia of Agriculture.' That of Wilson, published by Fullarton; and that of Morton, published by Blackie, are also useful as books of reference. The works of Professor Low, and Henry Stephens, of Edinburgh, may also be consulted. The Journals of the Agricultural Societies of England and Scotland, and the weekly agricultural papers, 'Bell's Messenger,' 'Gardeners' Chronicle,' 'Mark Lane Express,' and 'North British Agriculturist,' are full of valuable agricultural information.

The French are rich in elementary works, among which the 'Théâtre d'Agriculture,' par Olivier de Serres, is a standard work. It was written at the express desire of Henry IV. and his minister Sully, and published in 1600; the last edition, in four volumes quarto, Paris, 1804, with numerous additions, and the 'Cours Complet d'Agriculture,' by various members of the Institute of France, published in 1820, contain everything that was then known of the science of agriculture. A little work of much merit may be mentioned, called 'Le Manuel Pratique du Laboureur,' by Chambouillé Dupetitmont, Paris, 1826, two volumes, duodecimo; and also 'Le Calendrier du bon Cultivateur,' by C. I. A. Mathieu de Dombasle (on the plan of Arthur Young's 'Farmer's Calendar'), Paris, 1833, duodecimo, is a very useful work. The 'Journal d'Agriculture Pratique' is another more recent valuable agricultural periodical. Numerous works on particular branches, and the annals and memoirs of various agricultural societies, are constantly being published. Among the German authors we shall only mention Thaer, whose works we have quoted above, and which form a most complete body of theoretical and practical agriculture: his experiments made on a large scale at the national farm of Mögelin near Frankfort on the Oder, and repeated for many years, can be fully depended upon. We have also quoted the work of Mr. van Aelbroek, 'De l'Agriculture Pratique de la Flandre,' Paris, 1830, octavo, as a useful and interesting work.

ARACHIDIC ACID ($C_{40}H_{40}O_4$). A crystalline acid found in the oil expressed from the seeds of the *Arachis hypogæa*, a plant growing in Guinea and Brazil. It crystallises in small brilliant plates, which fuse at 167° Fahr., is very slightly soluble in cold alcohol, but easily soluble in boiling absolute alcohol and in ether. Arachidic acid forms an ether and an extensive series of salts which have recently been investigated by Gœssman and Scheven ('Ann. der Chimie u. Pharm.,' xcvii. 257). It also forms a compound with glycerin termed *Arachine.*

ARACHINE. [ARACHIDIC ACID.]

ARACK, or ARRAC. This word is derived from the Arabic word *arak*, which properly signifies perspiration. Under various modes of spelling it is employed as a general name for distilled spirits along the northern coast of Africa, including Egypt, over all Asia, and even in the north and eastern parts of Europe. This spirit is prepared from different substances, from the juice of the areka palm and rice, from palm-sugar and rice, but more especially from the sweet juice (toddy) extracted from the unexpanded flowers of different species of the palm tribe. The best sorts are produced at Goa, Batavia, and Ceylon. In Ceylon, where a large quantity of arack is manufactured, it is entirely distilled from coco-nut tree toddy. The 'toddy topes,' or coco-nut tree orchards, are very extensive in Ceylon, and their produce is collected for the distillation of arack, and the manufacture of sugar, vinegar, and oil: the latter chiefly, for the production of which steam-machinery is employed.

In Ceylon, when it is intended to draw toddy from a tope, the toddy-drawer selects a tree of easy ascent near to the centre of the tope, the stem of which he surrounds with a number of bands made of creepers, about a foot distant from one another. Upon these bands he ascends the tree, and by means of the stems of creeping plants or *coir* ropes, he connects the heads of a number of trees, so as to enable him to pass from tree to tree in the subsequent operation of collecting the produce.

The ordinary implements of a toddy-drawer are a large broad knife, which he carries in a coffer or basket suspended by a cord tied round his body; a mallet, consisting of a piece of hard wood about a foot in length; and the shell of a large gourd, which is suspended round his waist. When a tree is in a state fit for yielding sweet juice, the toddy-drawer ties the flowering spath in different places, by means of the white leaves of young branches. This process has the effect of preventing a bud from blowing. The spath is then bruised along its whole length by means of slight blows with the mallet or bat of hard wood. This operation occupies a few minutes, and requires to be regularly repeated every morning and evening for six or seven days. In a few days after the spath has been tied, a few inches of it is cut off by means of the broad knife. Two or three days after it is thus truncated, sweet juice exudes from the cut surface, which is received in an earthen vessel attached to the spath. The liquor issues, drop by drop, and a good healthy blossom will yield from two to four English pints in twenty-four hours, and continue to afford that quantity for a period extending from three to five weeks. As the coco-nut tree blossoms every four or five weeks, two spaths on one tree sometimes yield sweet juice at the same time. The toddy-drawer generally ascends the trees, for the purpose of collecting the sweet juice that has exuded into the toddy pots, both morning and evening, and to cut off a fresh portion of the flowering spath. The toddy is poured from the earthen vessels into the gourd, which is conveyed to the ground by means of a line. The gourd is emptied into a large vessel by a person at the foot of the tree, and drawn up by the toddy-drawer for the purpose of being refilled.

Arack may be distilled from toddy the same day it is drawn from the tree, but sometimes this operation is delayed until it becomes sour. The process of distillation is carried on in the maritime provinces in copper stills, but in the interior of the island earthen vessels are chiefly employed. Toddy yields by distillation about one-eighth part of proof-spirit.

On the peninsula of India, arack is distilled from the flowers of the *Bassia longifolia*, Tell mee (*Cingalese*), the *Máhwah*-tree, and the *Bassia latifolia*. Mahwah-arack may be procured at the rate of an English pint for less than one penny.

Arack is prepared in the island of Java, where it is known by the name of *kneip*, from a mixture of molasses, palm-wine, and rice. The rice is first boiled, and after being cooled, a quantity of yeast is added to it and pressed into baskets. Each basket is placed over a tub for about eight days, during which time a quantity of fluid passes through the basket into the tub; this fluid is added to the molasses and toddy in large fermenting vats, where the mixture is allowed to remain until it is fit for distillation.

In most parts of Turkey, arack (*raki*) is made from the skins of grapes. It is flavoured with aniseed, and sometimes contains a solution of gum-mastic. The mountain Tartars distil it from sloes, elder berries, wild grapes, plums, &c., and the Calmuck Tartars distil it from milk. The chief markets for arack are the East India Presidencies, to which a large quantity is supplied by Ceylon. In Europe Amsterdam is the chief place of importation, principally if not entirely from Batavia.

ARÆO'METER. [HYDROMETER.]

ARÆOSTYLE (from ἀραιὸς, *rare* or *few*, and στύλος, *a column*), a term used by writers on architecture, who follow the system of Vitruvius, for one of his "five species of temples." As the term itself imports, it refers rather to the arrangement of columns than to the composition or structure of a temple. The kind of temple called aræostyle is, according to Vitruvius, that in which "the columns are placed more distant from each other than in fact they ought to be." This, the commentators upon that writer say, is when the space between columns, or the intercolumniation, is from four to five diameters. The aræostyle intercolumniation is generally assigned by the same authorities to what in the Vitruvian system is called the Tuscan order; for as the remains of the more classical architectural works of the Greeks and Romans, on which the system *professes* to be based, exhibit no examples of either the aræostyle intercolumniation, or of the Tuscan order of columns, each could with safety be assigned to the other. [TEMPLE.]

ARÆOSYSTYLE. This term is compounded of *aræo* and *systyle*, and was formed to designate an arrangement of columns not mentioned by Vitruvius. The French architect, Perrault, is understood to have introduced the term aræosystyle to designate an alternately very wide and very narrow intercolumniation, or what is familiarly called coupled columns. This arrangement is alternately *aræostyle*—columns too far apart; and *systyle*—columns too close together. Perrault's front of the palace of the Louvre in Paris, the western portico of St. Paul's cathedral, the porticoes, pavilions, and colonnades of Buckingham palace, and many other edifices in London, exemplify the mode of arranging columns which the term aræosystyle designates.

ARAMÆAN or ARAMAIC LANGUAGE (לָשׁוֹן אֲרָם, or אֲרָמִית, from the unusual root אָרַם, which is related to the cognate forms רוּם, רָמַם, חָרַם, עָרַם, רָאַם, *to be high*, or *he was elevated*), literally means the Highland dialect, in contradistinction to לָשׁוֹן כְּנַעַן, the language of Canaan, or the Lowland dialect. The Aramæan was thus denominated because those parts of Aram which bordered upon Palestine were higher than the territory of the Jews, and especially higher than the coast of the Mediterranean Sea inhabited by the Canaanites. Thus a designation became current which was improperly applied to the whole of Aram, many parts of which had a lower level than Canaan, but passed under the general appellation of Highlands, because Aram bordered by Mount Lebanon upon Palestine, and had a higher level in all points of immediate contact. Aramaic is spoken near Mardin and Mosul (see Niebuhr's 'Reisebeschreibung nach Arabien,' t. ii. p. 352; and its French translation of 1780, t. ii. p. 275), where it is asserted that the Syriac is also spoken in several villages of the government of Damascus. Niebuhr calls the Christian idiom Chaldee. The Christians of Mardin and Mosul write even the Arabic in Chaldee characters, and the Maronites in Syriac letters. W. G. Brown mentions in his travels that the Syriac is spoken at Malala and Wara. Compare the 'Journal of a Residence at Bagdad,' by Anthony Groves, 8vo, London, 1832. It is also said to be spoken in some of the dales of the mountains of Kurdistan. The Aramæan is, on the whole, the poorest and the least refined of all the Semitic languages; yet Julius Fürst, in his 'Lehrgebäude der Æramäischen Idiome mit Berzug auf die Indo-Germanische Sprachen,' &c., published at Leipzig in 1835, has shown the great probability of the Aramæan having been the mother tongue of all the Semitic languages, and of its having had much influence on those of Indo-Germanic origin.

The Aramæan language comprises two principal dialects, the Babylonian or East-Aramaic (which is usually, but improperly, called Chaldee), and the Syriac or West-Aramaic dialects; both dialects, though nearly extinct, are yet spoken by a few tribes dwelling in the ancient Aram. This fact, mentioned by various travellers, we find also recorded in the 'Journal' of Mr. Groves. The Samaritan and Palmyrene were minor dialects of this language.

The sections in Daniel and Ezra called Chaldee, and a few words in Jeremiah and Genesis, are the most ancient remains of the East-Aramaic dialect, which is called by the Jews לְשׁוֹן תַּלְמוּד, that is, the language of the Talmud, or the language of learning, because parts of the Talmud and many rabbinical writings are composed in this idiom, which is now usually written and printed in the Hebrew square characters, or לְשׁוֹן תַּרְגּוּם, that is, the language of translation, because the Targums of Onkelos and Jonathan are paraphrastic translations of the Old Testament into the East-Aramaic language.

The oldest specimens of the West-Aramaic are much later; they consist of some Palmyrene inscriptions, one of which has been referred to A.D. 49. The characters of the West-Aramaic or Syriac differ greatly from the Hebrew. [SYRIAC LANGUAGE.]

The Aramaic is one of the Semitic dialects spoken by the descendants of Shem. Many forms of nouns and verbs, which in Hebrew and Arabic are polysyllabic, are shortened in Aramaic into monosyllables. The forms of nouns in Aramaic are less numerous than in Hebrew and Arabic. The dual is rare in the East-Aramaic. The personal pronoun of the second person singular combines both genders in one form אַנְתְּ.

Thus we see that the Aramaic has fewer grammatical forms than the cognate dialects, but we observe the reverse in the following instances.

The Aramaic has four active and four passive modifications, under every active modification, two participles, one of which has a passive signification, although the passive modifications have their own participles. The third person plural of the preterites distinguishes the genders by means of a double formation. A present tense is formed by the combination of participles with the personal pronoun.

While the Jewish community maintained its political independence in Palestine, the Hebrew continued to be the common language of the country, and, so far as we are able to judge, although not entirely pure, was, during that time, free from any important changes in those elements and forms by which it was distinguished from other languages. A few foreign words only had crept in along with the products of foreign commerce, arts, and inventions; and these, in consequence of the want of appropriate terms in the language of the country, received the right of citizenship. Even in the time of Hezekiah, the Hebrew dialect differed so much from the Babylonish-Aramæan, chiefly, it is probable, in respect of pronunciation, that the latter sounded in the ears of the common people of Jerusalem like an entirely foreign language, and was intelligible only to the principal officers of the court (comp. 2 Kings xviii. 26). But when the Assyrian and Chaldæan rulers of Babylon subdued Palestine, everything assumed another aspect. The Jews of Palestine lost, with their political independence, the independence also of their language. The Babylonish-Aramæan dialect supplanted the Hebrew, and by degrees became the prevailing dialect of the people.

The Babylonish-Aramæan language was very closely allied to the Hebrew; it stood to it in nearly the same kind of relationship as the Lower Saxon does to the High German. Both were the offspring of the original Semitic language, which was used from the Halys in Cappadocia to the regions beyond the Tigris, and from the source of the Tigris to Arabia. Both of these, as well as the other Semitic dialects, had the same stock of ancient radical words, and essentially the same grammar. The principal features of their difference were, that many words of the old primitive language remained current in one dialect, which were entirely or partially lost in the other, for example, the verb שְׁמַשׁ (to expose to the sun, or to dry) in Aramean, of which only the noun שֶׁמֶשׁ (sun) remained in the Hebrew. The same word was sometimes in use in both dialects, but in different significations. The Babylonish dialect borrowed expressions from the northern Chaldæans, who made an irruption into the country. Traces of such additions are to be found in the names of the officers of state, and other terms having reference to the government. The Babylonish pronunciation was easier of utterance, and more sonorous than the Hebrew.

The numerous Aramæan colonies (2 Kings xvii. 24), which were substituted for the subjects of the kingdom of Israel, carried to Assyria by Shalmaneser, retained their former language, and caused it to spread in the neighbourhood of their places of residence, even before the destruction of the kingdom of Judah. At a later period, the Babylonish-Chaldæan governors who ruled over Palestine; the standing forces which they had brought with them for the preservation of tranquillity, and which were composed of Aramæans and Chaldæans (2 Kings xxiv. 2); the host of foreign officers in their train, and the transactions of all public business in the Babylonish-Aramæan dialect, must have greatly tended to restrain the use of the national Hebrew dialect, since the Jews, who held public offices, or stood in any other near connection with the new rulers, were compelled to become familiar with the ordinary dialect of these rulers. There is also reason to suppose that the Babylonish had still earlier been the court language at Jerusalem (see 2 Kings xviii. 26).

The Aramæan language derives peculiar interest from having been spoken generally by the inhabitants of Palestine, from the Babylonian captivity to the final and general dispersion of the Jews. We find that Jesus Christ, when repeating on the cross the beginning of the twenty-second Psalm, does not quote the Hebrew original, but the Aramaic version. Many other occasional quotations and expressions used in the New Testament and in the writings of Josephus indicate the prevalence of the Aramaic language in Palestine in the age of Christ. The oldest Syriac version of the New Testament, the Peshito, is stated to be contemporary with the Apostles, or, at least, not later than the 1st century; and a valuable addition to Syriac literature has been made by the Rev. Wm. Cureton, by his publications, in 1845, of the 'Ignatian Epistles;' in 1858, of 'Remains of a very Ancient Recension of the Four Gospels in Syriac;' 'Fragments of the Iliad of Homer,' in 1851; and 'Spicilegium Syriaca;' together with other works in the same language, chiefly from MSS. obtained by Archdeacon Tatham from the monasteries of Syria, and M. A. Pacho, in Egypt. These interesting MSS. are now in the Library of the British Museum. The Greek, however, had been long firmly established in Palestine, where it was first introduced by the Macedonian conquests, and extended under the dynasty of the Seleucidæ. We know, both from positive testimony and the indirect evidence of inscriptions, &c., that Greek must have been as common in Palestine at this period as the French now is in Alsace, though it was no more the native tongue than French now is in the province just mentioned. Greek was also the language of science and learning, as it contained nearly all the knowledge which at that time existed. Concerning the language of Palestine in the age of Christ, compare the dissertations of De Rossi and Pfannkuche, and a chapter in Hug's introduction to the New Testament; which have been translated, partly in America, by Robinson, in the 'Biblical Repository,' for 1831, and partly in Edinburgh, in the 'Biblical Cabinet,' vol. i. 1833. The standard work on the Aramaic language is 'Andreæ Theophili Hofmanni Grammaticæ Syriacæ libri tres, cum tabulis varia Scripturæ Aramaicæ genera exhibentibus,' Halæ, 4to, 1827. Gesenius has since published a 'Thesaurus Philologico-critico' of the Hebrew and Chaldee Old Testament, in 3 vols., 1828-42; and Julius Fürst, a small Hebrew and Chaldæan Dictionary, in 1835.

English readers may compare Yates's 'Syriac Grammar; Harris's 'Chaldee Grammar,' 8vo, 1824; and ספר השרשים, a Hebrew and English Lexicon, containing all the words of the Old Testament, with the Chaldee words in Daniel, Ezra, and the Targums, and also the Talmudical and Rabbinical words derived from them, by Selig Newman, 8vo, London, 1834.

Strabo calls the Aramæans ('Geogr.' i. p. 112, ed. Siebenk.) Ἀρμενίους καὶ Ἀραμαίους, and Ἀρίμους. Comp. Stephanus Byz. under Ἄριμα; and Gesenius, 'Commentar zum Jesaiah,' t. i. 688, to chap. xxii. 6.

AR'BITER was a term in the Roman law signifying a judge invested with a discretionary power, and was applied to different kinds of judicial functionaries. The *arbiter compromissarius* answered to the arbitrator of modern jurisprudence, whose office will be treated of under the article ARBITRATION.

Another species of arbiter, peculiar to the law of Rome, partook more nearly of the character of an ordinary judge. In order to understand the nature of his office, it must be borne in mind, that all actions were commenced, and the preliminary proceedings carried on, before the prætor, technically termed (*in jure*); and when the altercations of the parties formally expressed had raised a question of fact disputed between them, a person was nominated in the formula to whom the adjudication of this fact was referred, whose title and powers depended on the contents of the formula. The different kinds of actions known to the Roman law were divided into three classes; actions of strict law, actions of good faith, and arbitrary actions: under the first class were comprehended all actions upon contracts called unilateral, that is, where only one of the parties is bound, as in the case of money borrowed, where the borrower is bound to repay, but no further obligation lies upon the lender. In these actions the person appointed to adjudicate was styled a judge (*judex*), and the only question for him to decide was, simply whether the plaintiff had completely established his case as originally stated.

In the two other classes of actions the person appointed to adjudicate was allowed a greater latitude of judgment, and was styled an arbiter. Actions of good faith were such as were founded on bilateral contracts, that is, on contracts by which an obligation is imposed on both parties, such as the contract of sale, where the seller is bound to deliver the goods, and the purchaser to pay the price. In all these actions the arbiter was not compelled, as in actions of strict law, either to grant or to reject altogether the claim of the plaintiff, but might enter into the merits of the case, and decide according to what seemed to him to be just and equitable between the parties. For the object of these actions was to obtain the fulfilment of such agreements as every honest man ought to be willing to execute, an object expressed in the formula, "Quidquid dari filii oportet ex fide bonâ."

To the third class, namely, that of arbitrary actions, belonged those chiefly in which the restitution of property, or some specific performance, was required of the defendant. In these cases the arbiter had authority to estimate the just claims of the plaintiff, and to condemn the defendant to some greater penalty, as, for instance, to pay fourfold in case of his not performing the judgment. Properly speaking they were actions not tied down by the *strictum jus*, but capable of receiving such modifications as the arbiter pleased, therefore they did not include the conditiones, or the actiones civiles ex delicto, whilst they did include those bonæ fidei, in rem, and prætoriæ; at the same time it is as well to bear in mind that these arbitrary actions did not embrace all unrestricted actions whatever, in spite of the modifications of which they were susceptible by means of the arbitraria formula; for though every arbitraria actio was an arbitrium, every arbitrium was not an arbitraria actio.

(Just. *Institut.* lib. iv. tit. 6; Heineccii, *Elem. Jur. Civ.* §§ 1181, 1196; Idem, *Antiq. Rom.* iv. 6, 36; Abdy, *On the Roman Law of Civil Procedure*, chaps. iii. iv.)

ARBITRATION is the adjudication upon a matter in controversy by private individuals selected and appointed by the parties. This mode of settling differences is very frequently resorted to as a species of amicable litigation, and a means of avoiding the delay and expense of a lawsuit, and the publicity of a trial. It has the further advantage of providing an efficient tribunal for the decision of many causes—such, for instance, as involve the examination of long and complicated accounts,—which our ordinary courts of law are, from their mode of proceeding and the want of proper machinery, incompetent to investigate.

The person appointed to adjudicate is called an arbitrator, or referee. The matter on which he is appointed to adjudicate is said to be referred or submitted to arbitration. His judgment or decision is called an arbitrament, or, more usually, an award.

Any matter actually in controversy between private persons may be referred to arbitration. By the 11th section of the Common Law Procedure Act, 1854, provision has been made in the case of prospective agreements to refer any differences which may hereafter arise. By that section, whenever, in spite of such agreement to refer, an action or a suit in equity has been commenced, power is given to the court, on the application of the defendant or defendants after appearance and before plea or answer, if satisfied that there is no reason why such reference to arbitration as agreed on should not be made, and that the defendant is ready and willing to concur in all acts necessary for causing such matters to be decided by arbitration, to make a rule or order staying all proceedings in such action or suit, on such terms as the court may think fit. No injury can be the subject of an arbitration, unless it is such as may be a matter of civil controversy *between the parties*: a felony, for instance, which is a wrong, not to the party injured merely but to society in general, is incapable of being referred.

There are no particular qualifications required for an arbitrator. In matters of complicated accounts, mercantile men are usually preferred. In other cases, it is generally considered advisable to appoint barristers, who, being accustomed to judicial investigations, are able to estimate the evidence properly, to confine the examination strictly to the points in question, and, in the making of the award, to avoid those informalities for which it might afterwards be set aside. Both time and expense are thus saved by fixing on a professional arbitrator. Any number of persons may be named as arbitrators: if the number is even, it is usually provided that, if they are divided in opinion, a third person shall be appointed, called an umpire, to whose sole decision the matter is then referred. [UMPIRE.]

A dispute may be referred to arbitration, either—1. When there is an action already pending between the parties relating thereto, or—2. When there is no such action.

1. In the former case, the parties to the action, if *sui juris*, are in general competent to submit to arbitration. The reference may be made at any stage of the proceedings; if an action is pending, it is effected by a rule of the court in which the action is brought, or by a judge's order, in which case it may be made a rule of court even after the submission has been revoked by one of the parties; if at the trial, by an order of Nisi Prius, with the consent of both parties by their counsel and attorneys. The usual mode of proceeding then is for the parties to have the jury sworn, and to consent that a verdict shall be given for the plaintiff for the damages laid in the declaration, subject to the award of the arbitrator. This is essentially necessary in bailable actions, otherwise the bail would be discharged by the reference. By the 17 & 18 Vict. c. 125, among other important alterations on the subject of arbitration, the third and sixth clauses have given extended powers to the judge engaged upon the trial of any issue of fact; by the third section the court or judge, upon the application of either party at any time after the issuing of the writ, may, if satisfied that the matter in dispute consists wholly or in part of accounts, order it to be referred to arbitration; and by the sixth clause, if it shall appear to him that the questions arising thereon involve matter of account which cannot conveniently be tried before him, he may, at his discretion, order it to be referred to arbitration either as to all or part of the matters in dispute.

The person named as arbitrator is not bound to accept the office, nor, having accepted, can he be compelled to proceed with it. In either case, if the arbitrator refuses or ceases to act, the reference is at an end, unless the contingency has been provided for in the submission, or unless both parties consent to appoint some other person as arbitrator in his stead.

Previously to the statute 3 & 4 Will. IV. c. 42, the authority of the arbitrator was revocable by either party at any time before the award was made; but by that statute it is declared that the authority of an arbitrator cannot be revoked by any of the parties without the leave of the court or a judge: but it is still determined by the death of any of the parties, unless a clause to obviate this is inserted in the submission; and if one of the parties is a single woman, her marriage, being in law a civil death of all her rights, will have the same effect. The order of reference usually provides that the award shall be made within a certain period; and if the arbitrator lets the day slip without making his award, his authority ceases, but a clause has usually been inserted to enable the arbitrator to enlarge the term: and now also by 17 & 18 Vict. c. 125 § 15, where an arbitrator is acting under any document or compulsory order of reference, he is directed to make his award within three months after the period of his appointment, unless the parties themselves have by consent enlarged the term for making the award, or the court or any judge thereof have from time to time enlarged the term. The authority of an arbitrator likewise ceases as soon as he has made or declared his award; but by statute 17 & 18 Vict. c. 125 § 8, power is given to the court or judge at any time, and from time to time, to remit the matters referred to the reconsideration and redetermination of the arbitrator.

When the arbitrator has accepted his office, he fixes the time and place for the parties to appear before him. Each of them furnishes him with a statement of his case, which is usually done by giving him a copy of the briefs on each side; and on the day appointed he proceeds to hear them (either in person, or by their counsel or attorneys), and to receive the evidence on each side, nearly in the same manner as a judge does at an ordinary trial: he is also invested by the order of reference with a power of examining the parties themselves if he think fit; but as by recent legislation the parties to suits, actions, or other proceedings in courts of law, are not merely competent, but are compellable, to give evidence for or against each other, it would appear to be the arbitrator's duty to examine the parties if required, even, it would seem, in cases where no action is pending.

No means existed of compelling the attendance of witnesses, or the production of documents, before an arbitrator, until the statute 3 & 4 Will. IV. c. 42, authorised the court or a judge to make an order to that effect; disobedience to which order, if served with proper notice of the time and place of attendance, becomes a contempt of court. The witnesses, thus compelled to attend, are entitled to their expenses in the same manner as at a trial. And where the order requires the witnesses to be examined upon oath, the arbitrator is by the same statute authorised to administer an oath or affirmation, as the case may require; and any person giving false evidence may be indicted for perjury.

The extent of an arbitrator's authority depends on the terms of the reference: it may either be confined to the action pending between the parties, or it may include any other specified grounds of dispute, or all disputes and controversies whatever existing between them at the time of the reference. Where the matters referred to him are specified, it is his duty to decide upon them all: where they are not specified, it is his duty to decide upon as many as are laid before him. In no case is an arbitrator authorised to adjudicate upon anything not in fact comprehended in the reference; such, for instance, as any claims or disputes which may have arisen after the reference was made, or, where the reference is specific, anything not expressly included in it. As nothing can be referred by the parties but the differences existing between themselves, an arbitrator can have no authority to bind any one who is not a party to the reference.

An arbitrator being a judge appointed by the parties themselves for the final settlement of their differences, his decision on the merits of the case submitted to him is conclusive; the question is set at rest, and never can be agitated between them again. But if his award be partially or illegally made, the superior courts have the power of setting it aside, upon application being made within the first seven days of the term next following the publication of the award to the parties. This happens either, 1. Where the award is not co-extensive with the arbitrator's authority; or 2. Where it appears on the face of it to proceed on mistaken views of law, or to fail in some of the qualities required for its validity [AWARD]; or, 3. Where any misconduct has been committed. This may happen in two cases: 1st, Where the arbitrators have been guilty of corruption or other misbehaviour, as, if they have proceeded to arbitrate without giving notice of the meeting, have improperly refused to receive evidence, or committed any other gross irregularity in practice; 2dly, Where it is proved that the arbitrator has been misled by fraud used by either of the parties. Where an award is absolutely void, as where it is made after the authority of the arbitrator has ceased, it is not in general necessary to set it aside, as it is incapable of being enforced.

When the award has been made and delivered, if one of the parties refuses to comply with it, the other may bring an action against him on the award. But the most prompt and efficient remedy is to apply to the court for an attachment, grounded on the contempt of court which he has been guilty of by disobeying the order of reference. But then the award must contain an order for the arbitrator to pay the money or do the act awarded, for otherwise the not doing of it will be no breach of the rule, and the court cannot grant the attachment. [ATTACHMENT, CONTEMPT.] In opposing this application, the other party may insist on any objection apparent on the award itself; but if there were any other objections affecting its validity, and he has neglected to apply to the court to set it aside within the time fixed by them for that purpose, it is too late for him to avail himself of them. It would appear, from some recent cases, that where there is a doubt as to the validity of an award, the court will neither enforce it by attachment nor set it aside, but leave the party to his remedy by action.

When, in the original action, a verdict has been taken, subject to an award or certificate, the party in whose favour the award is afterwards made, or certificate granted, may have the postea indorsed on the Nisi Prius record; and may, without any personal service of the award, sign judgment and sue out execution, without any previous application to the court, unless the reference is of the cause and all matters in difference, in which case the defendant is allowed the whole of the term after the making of the award to move to set it aside, until which time the award cannot be enforced.

2. Where no action has been commenced, the parties may refer their differences to arbitration by mutual agreement, either by mutual bonds of submission, or by deed, or by agreement not under seal, or by parol (but a parol or verbal submission cannot be made a rule of court, even with the consent of the parties). In these instruments it is of importance that the consent clause under 9 & 10 Will. III. c. 15, § 1 (referred to below) be introduced in order that the submission may be made a rule of court. Every person capable of making a disposition of his property may be party to such an agreement: no peculiar form is necessary for its validity.

Whether the submission be verbal or in writing, it is in the power of either of the parties to revoke it, and thus put an end to the authority of the arbitrator at any time before the award is made. In order to prevent this, it is usual for the parties to make it a part of their agreement, that they will abide by and perform the award; and if after this either of them should, without sufficient reason, revoke his submission, or otherwise prevent the arbitrator from proceeding with the arbitration, he will be liable to an action for the breach of his agreement.

The time for making the award may be enlarged, if there be a clause to that effect in the agreement of submission, or if all the parties consent to it, but not otherwise. But now, by 17 & 18 Vict. c. 125, § 15, the parties may, by consent in writing, enlarge the term for making the award; and if no period for the enlargement be mentioned, it shall be deemed to be an enlargement for one month. There are no means of compelling the attendance of witnesses, nor has the arbitrator the power of administering an oath; but the witnesses and—if they have agreed to be examined—the parties are sworn either before a judge, or, in the country, before a commissioner. They may, however, be examined without having been sworn, if no objection is made to it at the time.

The courts cannot enforce performance of the award by attachment; the only remedy is an action on the award itself, or rather on the agreement of submission; unless where the submission being in writing either contains the consent clause above mentioned, or does not contain words purporting that the parties intended it should not be made a rule of court: in which case the party in whose favour the award is made may have his remedy upon it by attachment. The defendant may insist on any objection apparent on the award itself, but where there is any other ground for setting it aside, his only remedy is by a bill in equity.

Thus it will be seen that where the reference is by agreement, many inconveniences occur, particularly from the deficiency of the remedies; but the legislature has enabled parties to put such references on the same footing as those which are made where a cause is depending, by enacting, by 9 & 10 Will. III. c. 15, § 1, that they may agree that their submission (which it is held in this case must be in writing) shall be made a rule of any of her majesty's courts of record (and in practice courts of equity have long enjoyed concurrent jurisdiction), and insert such agreement in their submission; and this submission may at any time afterwards be made a rule of court, by producing the affidavit of its execution made by a witness thereto. Moreover, by the stat. 17 & 18 Vict. c. 125, § 17, there is a further provision on this subject, by which any agreement or submission in writing may be made a rule of court, unless a contrary intention appear in such agreement or submission. The provisions of the statutes 3 & 4 Wm. IV. c. 41, and 17 & 18 Vict. c. 125, apply as well to arbitrations made in pursuance of such agreements of submission, as to those made by order of court; and the law is the same in both cases, except in some few points of practice.

The settlement of disputes by arbitration seems to have enjoyed in all ages a high degree of public favour. Aristotle, to give an instance of a metaphor that is appropriate without being obvious, quotes a passage from Archytas, in which he compares an arbitrator to an altar, as being a refuge for the injured. (Arist. 'Rhetor.' lib. iii. ch. xi.) There were at Athens two modes of proceeding which passed by the name of arbitration—the Greek word for which is diæta (δίαιτα). In the first of these the proceedings were of two kinds, first, when two parties agreed by a regular contract to refer a matter in dispute to a judge or judges selected by them; secondly, when a cause was brought before a public arbitrator in regular course of law. Except in one point, that of non appeal, which seems to have been the rule applicable to the former of these two kinds, there was no difference between them; the arbitrator in each case being subject to the same liabilities, and standing in the same relation to the parties, and the form of proceeding being the same (Dem. 'c. Meid.'). The arbitrators appear to have constituted what in modern jurisprudence would be called a Court of Reconcilement. A certain number of persons, of a specified age, were annually chosen from each tribe, as official referees; and from among these the arbitrators to decide upon each particular case were afterwards also chosen (Petit. 'Leges Atticæ,' p. 345; Dem. 'c. Meid.;' 'Heraldi de Rerum judicatarum auctoritate,' lib. ii. c. iv. s. iv.,) and were then bound to act under pain of infamy. They sat in a public court, and their judgments were subscribed by the archons. (Petit. p. 346.) An appeal lay from their decision to the ordinary courts; and sometimes the arbitrator referred the cause to their judgment at once, without pronouncing any sentence of his own. ('Heraldi de Rer. judic. auctor.' lib. ii. c. iv. s. iv.) In either case, all the writings connected with the trial were sealed up and delivered to the court before which the cause was brought. And it is said that originally no action could be introduced into the ordinary courts without having been first carried before the Court of Arbitrators. (Petit. p. 345; Pollux, viii. 10.) Their jurisdiction, however, was confined to Athenian citizens, and they took no cognizance of suits in which the sum in dispute was less than ten drachmæ, such smaller actions being disposed of in a summary manner by a special tribunal. (*Ibid.*) The litigant parties paid the expenses of the arbitration. (Boeckh, 'Public Œcon. of Athens,' i. 316, English Trans.) When their year of office expired, the arbitrators were liable to be called on for an account of their conduct, and if found guilty of corruption or misconduct, were punished with infamy.

In the other mode of proceeding, which was strictly in accordance with the definition which we have given of arbitration, the parties were at liberty to refer their differences to whomsoever they chose, and such referees were therefore distinguished by the title *αἱρετοί*, who were not, however, selected from the diætetæ of the tribes. The submission was generally made by a written agreement signed by the parties, which frequently contained an engagement by third persons to become sureties for its performance. (Demosthenes's 'Speech against Apaturius,' chap. 4.) The arbitrator was not required to adhere to a rigid interpretation of the law, but might decide according to the individual merits of the case before him. (Arist. 'Rhet.' i. 14.) There lay no appeal from his award to any other tribunal whatever. Though an instance is to be found in Demosth. ('c. Apat.') of a party having persuaded his opponent to leave a matter to the arbitration of three persons, and afterwards finding that they were likely to decide against himself, going before one of the public arbitrators. (See the law quoted by Demosthenes against Meidias, chap. 26.) On the subject of the Diætetæ, see 'Dictionary of Greek and Roman Antiquities,' art. Diætetæ, and Hudtwalcher 'Ueber die öffentlichen und privat Schiedsrichter Diäteten in Athen, und den Process vor denselben.'

The Roman law upon this subject is much better understood, and is of infinitely greater importance. Its influence has extended over the whole of Europe, and even in our own country it is evident that references made by virtue of a mutual agreement—apparently the first species of arbitration known in our law—are mainly founded upon the doctrines contained in the 'Digests' of Justinian, lib. iv. tit. 8. The only mode of referring a matter to arbitration in the Roman law, was by an agreement called *compromissum*, which contained the names of the arbitrators (hence called *arbitri compromissarii*), the matters intended to be referred, and an undertaking by both parties to abide by the award, or in default thereof to pay to the other a certain sum of money as a penalty. The rule which forbids matters of public interest to be submitted to the judgment of a private referee, was not confined in its operation to criminal prosecutions and penal actions only, but extended to these arbitrations, by allowing the arbitrator the power of refusing to entertain (*rector non compellatur sententiam dicere*), any question affecting the civil condition (*status*) of any individual,—his freedom, for instance,—as well as by withdrawing from his decision all questions arising out of the *actiones populares*, and out of actions in which an adverse verdict would result in *infamia*.

The persons named as arbitrators were not bound to undertake the office, but having once done so, they might, by an application to the prætor, be compelled to go through with it. Their authority was, however, terminated by the death of either of the parties, unless his heirs were included in the submission; by the expiration of the time limited for the decision; by either party having broken the agreement, and so incurred the penalty; or by his becoming insolvent, and his property in consequence of a *cessio bonorum* being vested in his creditors.

Their authority also ceased by what we should call an implied revocation, if the subject matter of the reference perished, or if the parties settled the dispute in some other way, referred it to other arbitrators, or proceeded with an action respecting it. The death of the arbitrator, too, put an end to the reference, for the principle on which the appointment of arbitrators rested, was that the arbitration was a personal matter, and did not pass to a successor. Besides the cases in which his authority was thus at an end, an arbitrator could not be compelled to proceed with the reference if he could allege any sufficient excuse, as, for instance, that the submission was void, that there had arisen a deadly enmity between him and one of the parties, or that he had been prevented by ill-health, or by an appointment to some public office in the state; but all these excuses were referred to the prætor for his consideration, to whose jurisdiction belonged all questions connected with the reference.

The extent of the arbitrator's authority depended upon the terms of the submission, which might be either special or general. The submission usually appointed a certain day for the making of the award, but power was generally given to the arbitrators to enlarge the time if necessary, but they could not give their award on an earlier day without the consent of the parties. On the day originally appointed, or on that subsequently fixed by the arbitrators, they formally pronounced their award, and (unless it had been agreed otherwise) the parties were required to be present, and if one of them failed to appear, the award was not binding, but the party who had thus prevented the arbitration being completed incurred the penalty specified in the submission. If there were several arbitrators, all were bound to attend: they were not, however, required to be unanimous, but the opinion of the majority prevailed; and if they were equally divided, it is said that they might of their own authority appoint an umpire, and, in case of their refusing, the prætor had the power of compelling them to do so. When their award was pronounced, their authority expired, and they could neither retract nor alter their decision.

The award when made had not the authority of the sentence of a court of justice, nor was there any direct method of enforcing the performance of it; but as the parties had bound themselves to abide by the arbitrator's decision, if either of them refused to perform it, or in any other way committed a breach of his engagement, he was liable to an action; and however unsatisfactory the award might appear, there was no appeal to any other court. If, indeed, the arbitrators had been guilty of corruption, fraud or misconduct, or if they had not adhered to their authority, their award was not binding: there was, however, no direct method of setting it aside; but if an action was brought to enforce the award, such misconduct might be insisted on as an answer to it. (Heineccii 'Elem. Jur. Civ.' part i. § 531-543; Voetii 'Commentarius ad Pandect.' vol. i. pp. 290-300.

The Roman law was, with some slight modifications, adopted in France (Domat's 'Civil Law,' part i. book i. tit. 14; and 'Public Law,' book ii. tit. 7; Pothier, 'Traité de Procédure Civile,' part ii. chap. iv. art. 2), and notwithstanding the changes which have been introduced from time to time, it still forms the groundwork of the system. There are at present three kinds of arbitration; the first is voluntary arbitration, which is founded, as in the Roman law, upon an agreement of the parties. The mode of proceeding in this case is treated of at considerable length, and with minute attention to details, in the 'Code de Procédure Civile,' art. 1003-1028.

The ordinary courts exercise a much greater control over the proceedings in references than they do in England, but they have never had the power which the magistrates had at Rome—of compelling a person who had once undertaken the office of arbitrator to proceed with it; nevertheless, if he fail to do so, without a sufficient excuse, he is liable to an action for the damages occasioned by his neglect of duty. In order to understand clearly the peculiarities of the French system, it will be necessary to bear in mind that the proceedings before the arbitrators are much more nearly on the same footing with the regular administration of justice than is the case with us, and that many of the details are merely adopted from the practice of the ordinary courts: for instance, there is a system of local judicature established in France, and as the judge is resident in the neighbourhood of the suitors, it has been found necessary—in order to guard against partiality or the suspicion of partiality—to allow either party to refuse or challenge a judge, as in England they would challenge a juryman; and in the same manner an arbitrator may be challenged, but this can only be in respect of some objection which has arisen since his appointment, for the very act of appointing him is an implied waiver of any objections which might have existed up to that time; but if there is no ground for challenge, the arbitrator's authority cannot be revoked without the consent of both parties.

An arbitrator's decision or award is considered as a judgment, and all the formalities required for the validity of a judgment must therefore be observed; but execution of it cannot be enforced until it has received the sanction of the public authority; this sanction is conferred by a warrant of execution granted by the president of the tribunal within the jurisdiction of which the cause of the action arose: the granting of this warrant is called the homologation of the award. If the arbitrator has not strictly pursued his authority, the warrant of execution may be superseded, and the award declared null by an application to the tribunal from which the warrant issued. Besides this, the same modes of obtaining relief may be resorted to in the case of an award, as in that of any other judgment. If any misconduct or irregularity has occurred, the award may be set aside by what is called a *requête civile;* and even where nothing can be alleged against the formal correctness of the proceedings, if one of the parties be dissatisfied with the judgment, he is at liberty (unless the right has been expressly renounced) to appeal to a superior court: when this happens, the whole case is re-opened before the tribunal of appeal, and the merits investigated anew; and when an award is brought under the consideration of a court in any of these ways, any final judgment which the court may have pronounced may be brought before the Court of Cassation, and there quashed if erroneous in point of law.

The second kind, which is called 'compulsory arbitration,' and treated of in the 'Code de Commerce,' div. i. tit. iv. art. 53–64, is where the parties are by law required to submit to a reference, and are precluded from having recourse to any other mode of litigation. The ancient laws of France introduced this species of arbitration very extensively for the settlement of disputes respecting either mercantile transactions or family arrangements; but by the codes now in force, it is admitted in one case only, that of differences between partners. Over such differences the ordinary courts have no jurisdiction whatever in the first instance, even by the consent of the parties; but the commercial courts exercise a superintending and controlling authority over the proceedings. Thus the arbitrators may either be appointed by the deed of partnership, or afterwards nominated by the partners; but if, when a dispute has arisen, one of the partners refuses to nominate an arbitrator, or nominates an improper person, the commercial court, upon application made by the other partner, will appoint one for him; but the authority of the person so appointed will be superseded, if at any time before he enters upon his functions an arbitrator is duly nominated by the partner in delay: and when the firm consists of several partners, upon an application being made by any one of them, the court, after taking into consideration how far their respective interests are identical and how far they are conflicting, will regulate accordingly the number of arbitrators to be appointed by each. The sentence of the arbitrators, howsoever appointed, is decided by the majority of votes.

The authority of the arbitrators in this case partakes more of the judicial character than it does in voluntary arbitration; they are considered as being substituted for the ordinary commercial tribunal; their sentence is accordingly registered among the records of the court; and for the same reason also they stand upon the same footing with the court, both in the power of sentencing the parties to imprisonment, and, unless the right has been renounced by the parties, in the liability of appeal from their decision. ('Code de Commerce,' art. 51–64.)

Besides the compulsory arbitration in matters of partnership, the parties who enter into any engagement are at liberty to stipulate that all differences arising between them shall be submitted to arbitration. This stipulation is compulsory, and the court will, if requisite, appoint an arbitrator ex officio for the party who should refuse to do so; but it is not exclusive, so as to take away the jurisdiction of the ordinary tribunals; it may be rescinded by the consent of the parties, or waived by their acts.

The third kind of arbitration is distinguished by the appellation of the persons to whom the reference is made; they are not called, as in the other cases, *arbitres*, but *aimables compositeurs*, or, in the older law, *arbitrateurs*. The peculiar characteristics of this amicable composition are, that the referees are not, as in other cases, bound to adhere rigorously to the rules of law, but are authorised to decide according to what they conceive to be the real merits of the case; and that in the exercise of this discretion their decision is final, and without appeal to any other tribunal. In case of irregularity or misconduct, the award may be set aside by the judgment of a court, but this judgment cannot be further questioned in the Court of Cassation. This modification of the general law may be introduced into all arbitrations, whether voluntary or compulsory. (See Pardessus, 'Cours de Droit Commercial,' § 1386–1419.)

In Denmark and its dependencies, *Courts* of Arbitration or Conciliation were established about the year 1795, and are said to have been attended with extremely beneficial effects. In Copenhagen the court is composed of one of the judges of the higher courts of judicature, one of the magistrates of the city, and one of the representatives of the commonalty. In other towns, the chief magistrate proposes five or six of the more respectable citizens for arbitrators, of whom the commonalty of the town elect two, advocates being excluded from the list of candidates. In the country, the bailiffs or sheriffs are the arbitrators, and generally act as such personally; but in extensive districts they have authority to appoint deputies. All matters of civil litigation may be referred to these official arbitrators, who in the country sit once in every week, and in the capital as often as occasion requires. It appears that, after investigating a disputed case, the arbitrators in these tribunals have no power to compel the parties to settle their differences in the manner proposed by the court. If they agree, the terms of the arrangement are registered, and it has then the force of a judicial decree; if, after stating their differences and hearing the suggestions of the arbitrators, the parties still disagree, no record is made of the proceeding, and they are at liberty to discuss their respective rights in the ordinary courts of justice. It is necessary, however, that before a suitor commences an action in the superior courts, he should prove that he has already applied to one of the courts of conciliation. These courts, which are attended with very small expense to the suitors, were, soon after their establishment, multiplied rapidly in Denmark and Norway, and are said to have produced an astonishing decrease in the amount of contentious litigation. (See 'Tableau des Etats Danois,' par Catteau, tome i., p. 296.)

ARBLAST, or **ARBALEST**, was the name more particularly given to the cross-bow. Robert of Gloucester, in his 'Chronicle,' published by Hearne, p. 378, makes an especial difference between the bowmen and the arblastes, or arblasters, the cross-bowmen. In the Latin of the middle ages it is called 'arcubalista,' from *arcus*, a bow, and the Greek word βάλλω, to cast or shoot.

The precise date and origin of the arbalest is unknown; but it seems easily derivable from the larger species of ballistæ. Vegetius is inclined to consider the *scorpio* to be the same as the cross-bow: he speaks of scorpions, which he says they now name *manuballistæ;* and in later writers the modern weapon is sometimes termed *scorpio manualis.*

Pitiscus, in his 'Lexicon,' has assigned the introduction of the arbalest into the Roman armies to the time of Constantine, or a little earlier.

Strutt thought that the cross-bow was introduced into England about the 13th century; but Daines Barrington comes probably nearer to the truth ('Archæologia,' vol. vii. p. 46), when he inclines to the opinion that it was the arbalest, and not the long bow, which was used with such destructive effect at the battle of Hastings by the Normans. There can be little doubt but that the arbalest was introduced by the Normans at their first arrival. We have no mention whatever of it in any writer or document of the Saxon times; but in the 'Domesday Survey,' compiled in 1086, we have several *arcubalistarii*, captains of cross-bow men, among the tenants in chief. No such appellation is given in that record to any person who held lands in the time of King Edward the Confessor.

Brompton, in Twysden's 'Scriptores,' col. 1278, says, that the use of the arbalest having been laid aside, was revived by King Richard I., who was afterwards killed by an arrow shot from one at the siege of Chalus.

The arrows for the cross-bow were called quarrels, from the French *carreaux*. [ARCHERY.]

ARBORETUM. This name has been lately extended beyond its strict botanical meaning, and made to apply to public parks opened near large manufacturing towns. In 1837 a resolution was passed by the House of Commons to the effect that, in all new Enclosure Acts, some portions of the waste land about to be appropriated should be set apart for the healthful recreation of the neighbouring towns and villages. This resolution has led to the establishment of many places for open-air recreation.

Mr. Joseph Strutt, of Derby, made a munificent gift to the inhabitants of that town, in 1840, of an Arboretum or public park. He expended twelve thousand pounds in the purchase of eleven acres of ground at the south end of the town, and in laying out this ground with walks, lawns, plantations, and other accessaries. The late Mr. Loudon was employed to conduct the operations; and, in a pamphlet on the subject, he has given the reasons which induced him to determine on an Arboretum, instead of a botanic garden or a mere pleasure-ground. Near each tree and shrub is a small tablet, on which is written the catalogue number of the specimen, the Latin or scientific name, the English name, the habitat, the full-grown height, the date of the introduction, &c. By a deed of settlement the Arboretum is placed in the hands of the corporation of Derby, for the benefit of the inhabitants.

When the modern town of Birkenhead was laid out on so magnificent a scale, a public park was planned on a basis of unusual liberality. An open spot of 190 acres was so arranged, that 120 acres were laid out in shrubberies, lakes, walks, and drives for the free use of the inhabitants; while the remaining 70 acres were appropriated for handsome residences intended to border the park. Mr. (now Sir Joseph) Paxton was employed to form the park. The cost of the land and the laying out of the park was about 130,000*l*; and it was computed that the 70 acres would resell for building-ground at about the same sum; so that this excellent public-spirited arrangement would in effect cost nothing to the townsmen collectively.

In 1846-7 no fewer than three public parks were established in the neighbourhood of Manchester; namely, Peel Park, opposite Salford-crescent; Queen's Park, in the Rochdale-road; and Phillip's Park, in Ancoats. The purchasing of the estates and the formation of the parks were effected by a committee, to whose hands munificent donations were entrusted.

In 1852 an Arboretum was opened at Nottingham. It comprised an area of 18 acres, at the northern limits of the town; and it comprised, greenswards, paths, and drives, plantations of trees and shrubs, and a lake containing aquatic birds. This was not the gift of a private individual; it resulted from the provisions of an Enclosure Act passed in 1846.

About the same period an Arboretum was formed at Ipswich. Bradford and Liverpool soon afterwards recognised the importance of places of open-air recreation, whether called by the name of Arboretum or by any other name.

The metropolis has, within a comparatively small number of years obtained an addition of two to its former number of public parks. These are Victoria Park and Battersea Park, situated respectively at the north-east and south-west extremities of the Metropolis. Each contains the beginning of what may one day be an Arboretum. The unsightly Kennington-common has been converted into a park of humble pretensions. A park and arboretum for Finsbury have long been under consideration, but though an Act has been obtained for its construction, no steps have been taken for carrying it into effect. Hampstead-heath, so far as it contains the elements for an Arboretum, has been with difficulty preserved from the builders, who have covered so many other open spots near London with bricks and mortar.

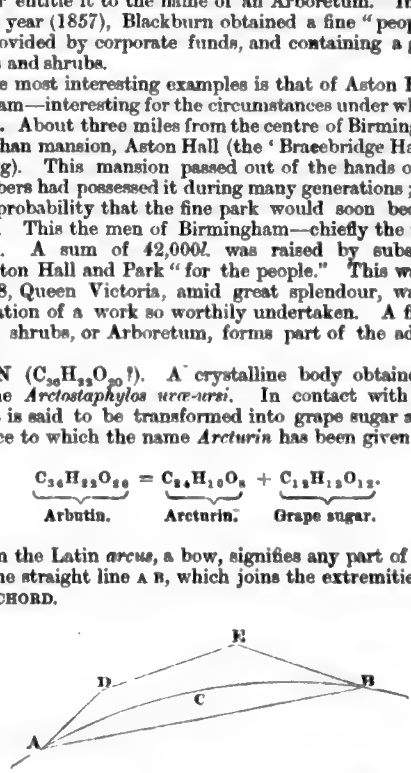
Without attempting to notice all the parks for the people, constructed and thrown open within the last few years, we must at any rate devote a few words of description to that at Halifax, munificently presented to the inhabitants by Mr. Crossley, a carpet manufacturer, and member for the borough. This park, which was opened in 1857, covers an area of about 13 acres; and cost, with the laying out of the grounds by Sir J. Paxton, no less a sum than 30,000*l.* Besides terraces, statues, vases, basins, fountains, a small piece of water, with a bridge, &c., the park contains a collection of trees, shrubs, and flowers, which so far entitle it to the name of an Arboretum. In the autumn of the same year (1857), Blackburn obtained a fine "people's park" of 50 acres, provided by corporate funds, and containing a goodly collection of trees and shrubs.

One of the most interesting examples is that of Aston Hall and park at Birmingham—interesting for the circumstances under which the work was effected. About three miles from the centre of Birmingham is a fine old Elizabethan mansion, Aston Hall (the 'Braeebridge Hall' of Washington Irving). This mansion passed out of the hands of the family whose members had possessed it during many generations; and in 1856, there was a probability that the fine park would soon become covered with houses. This the men of Birmingham—chiefly the working men—prevented. A sum of 42,000*l.* was raised by subscriptions, to purchase Aston Hall and Park "for the people." This was done; and in June 1858, Queen Victoria, amid great splendour, was present at the inauguration of a work so worthily undertaken. A fine collection of trees and shrubs, or Arboretum, forms part of the adornments of the park.

ARBUTIN ($C_{36}H_{22}O_{20}$?). A crystalline body obtained from the leaves of the *Arctostaphylos uvæ-ursi*. In contact with the ferment *Synaptase*, it is said to be transformed into grape sugar and a crystalline substance to which the name *Arcturin* has been given:

$$\underbrace{C_{36}H_{22}O_{20}}_{\text{Arbutin.}} = \underbrace{C_{24}H_{10}O_{8}}_{\text{Arcturin.}} + \underbrace{C_{12}H_{12}O_{12}}_{\text{Grape sugar.}}$$

ARC, from the Latin *arcus*, a bow, signifies any part of a curve line, as A C B. The straight line A B, which joins the extremities of the arc, is called its CHORD.



For the arc of a *circle*, see ANGLE, where the method of finding the arc from its angle, and the converse, is given. For the properties of the arcs of various curves, see their several names.

It is found necessary to assume the following axiom previously to any general investigation of the properties of an arc. Every arc is greater than its chord, but, when concave to the chord throughout, is less than the sum of the sides of any rectilinear figure which contains it. Thus A C B is greater than A B, but less than the sum of A D, D E, and E B. If x and y be the co-ordinates of any point in the curve, the general method of finding the arc is by the integration of the formula

$$\sqrt{dx^2 + dy^2},$$

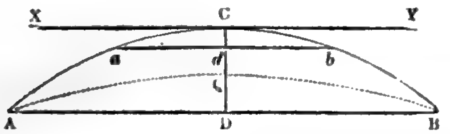
or, in the language of the fluxional calculus,

$$\text{fluent of } \sqrt{\dot{x}^2 + \dot{y}^2}.$$

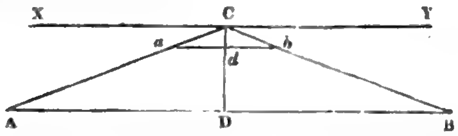
The practical method of finding the length of an arc, which is an approximation to the preceding process, is as follows:—Divide the arc into a number of smaller arcs, making the number large in proportion to the degree of accuracy required, and add together the chords of the smaller arcs. The sum of the chords will differ very little from the arc, even when the number of subdivisions is not very large. For instance, the arc of the quadrant of a circle, whose diameter is ten millions of inches, is 7,853,982 inches, within half an inch. Divide this quadrant into ten equal parts, and the sum of the chords is 7,845,910 inches: divide the quadrant into fifty parts, and the same sum is 7,853,659 inches, which is not wrong by more than one part out of 24,316. For only twenty subdivisions the sum of the chords is

7,851,963 inches, wrong only by one part out of 3890. Therefore, for every practical purpose, an arc of a circle (and the same may be said of every other curve) is the polygon made by the chords of a moderate number of subdivisions of the arc.

The preceding property is (but in what manner our limits will not permit us to show) a consequence of the following proposition. Let there be a number of arcs, such as ACB, cut off the same curve, having their chords parallel to the tangent XCY; then, as AB moves parallel



to its first position towards XY, CD not only decreases without limit but its proportion to AB decreases without limit; that is, let any number, however great, be named, then shall AB, before it reaches XY, reach a position in which it contains CD more than that number of times. This proposition is startling to the beginner in mathematics, and should be considered by him with great attention. It may be illustrated in the following manner:—Suppose that while AB moves from its first position towards XY, and has reached *a b*, a miscroscope moves with and over it, which increases in magnifying power as *a b* moves, in such a manner that *a b* always appears in the glass as large as AB to the naked eye. Then *a* c *b* will not be magnified into the form ACB, but into AQB, where QD grows less and less without limit, as *a b* approaches towards XY. But if two straight lines had been taken, as in the following figure, *a b* could not have been magnified to AB without changing *a* C *b* into ACB.



Formerly, the term arc was frequently confounded with angle, which arose from the practice of measuring angles by arcs of the circle. For such terms as ARC OF ELEVATION, &c., we refer to ANGLE OF ELEVATION, &c.

ARCADE signifies a series of arches on insulated piers, forming a screen, and also the space inclosed by such. This is, perhaps, a limitation of the term within that usually given to it; but arcade is properly a correlative of *colonnade*, and should not therefore have a more extensive signification. What, by a strange perversion of the term, are in this country called *piazzas*, and most particularly the part so termed of the buildings in Covent Garden, London, are strictly *arcades;* and the market within the inclosed area of that same place or square, to which the term *piazza* properly applies, exemplifies, in a great part of its exterior, the correlative term *colonnade*.

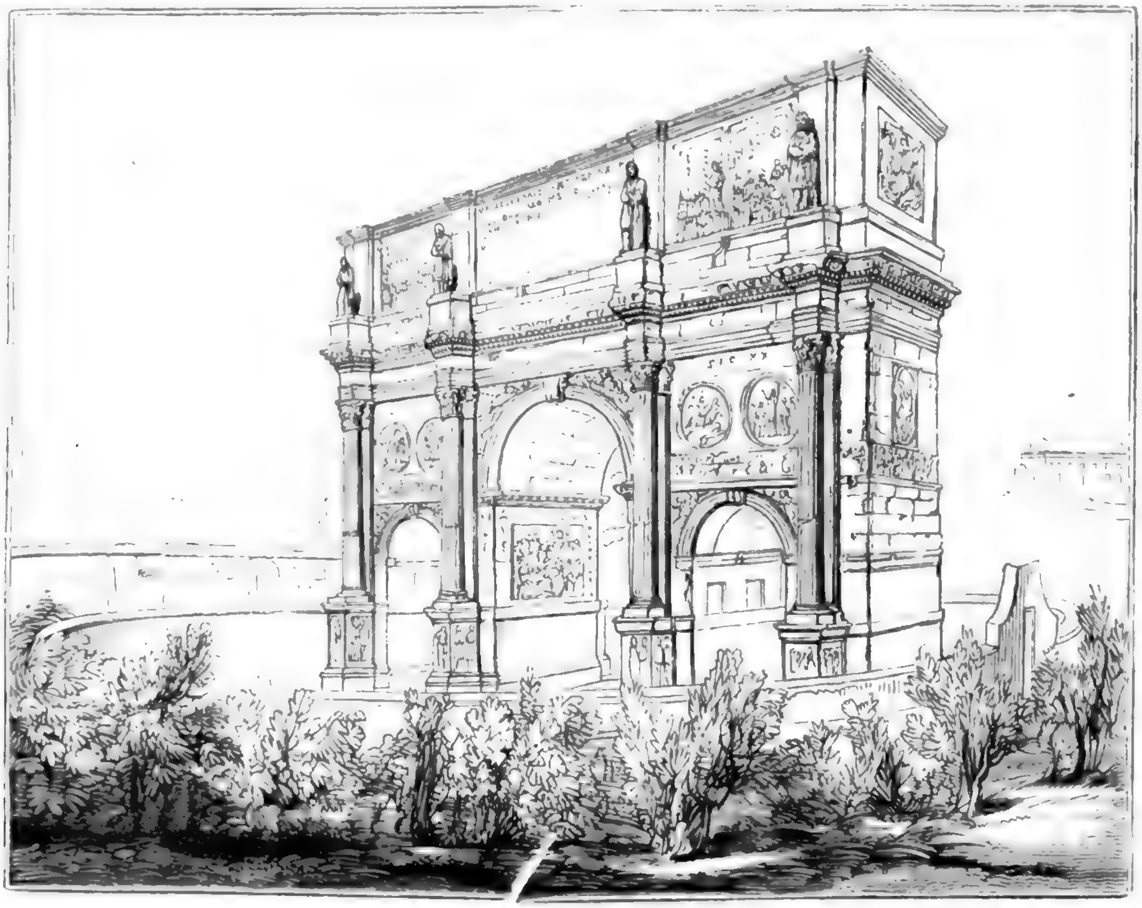
In Gothic architecture the term arcade is applied to a series of arches supported on piers, and used as decorations for the walls of churches, and occasionally of other buildings. The arches are sometimes open, but more commonly closed by the masonry of the wall. Good examples of arcades of the Norman and Early English styles (in which arcades are most employed) occur in Canterbury cathedral; of the decorated style in Lichfield cathedral: but most of our cathedrals possess some examples.

In addition to its proper technical meaning, this term has acquired a different signification among us as the popular name for what the Parisians more properly designate a 'passage' or 'galerie,' namely, an alley lined on each side with shops, and roofed over so as to be in fact a sort of 'in-door' street, entirely protected from the weather, and of uniform design throughout in its architecture. So far, an arcade answers to the idea of a bazaar, the chief distinction between the two being that the latter has not so much of street character about it, but consists either of a single spacious hall or separate rooms, fitted up with counters and stands, and may therefore be likened to a single large shop occupied by a number of different dealers, whereas in an arcade the shops are quite distinct from each other, and enclosed in front with windows after the usual manner; and they have besides dwelling accommodation, kitchen, &c., beneath, and a chamber over them, with the addition sometimes of an entresol. Another distinction is that an arcade serves as a public thoroughfare for foot-passengers. The Burlington Arcade, which was the first place of the kind in London, has indeed little more than its convenience as a thoroughfare and promenade for foot-passengers to recommend it, inasmuch as it makes no pretensions to elegance of design, nor has it anything in accordance with the title bestowed on it, it being neither arcaded in any way nor arched over. The Lowther Arcade in the Strand (erected 1831) manifests a great improvement upon that first specimen, for it is really a handsome piece of architecture; the side elevations are divided by pilasters into compartments, each of which contains a shop-front, with an ornamented triple window over it, and above that a semicircular one in the arched head of the compartment. On the plan, each of these divisions is covered by a pendentive dome with a circular skylight; and these numerous domes and their arches produce a pleasing perspective effect. Three other arcades have been opened in London since the erection of the Lowther Arcade. The first of them, Exeter Arcade, running from Wellington Street to Catherine Street in the Strand, erected in 1844 from the designs of Mr. Sidney Smirke, is very short; is more enclosed than either Burlington Arcade or Lowther Arcade; has a vestibule at each end; is glazed, so that the lights form a continuous skylight, and has polychromic embellishment applied both on the upper part of the walls (in ornaments and panels between the windows over the shops) and on the cove of the ceiling. The whole place has indeed more the appearance of a hall or gallery than of a place of thoroughfare and business. The arcade in New Oxford Street, opened in 1851, is short but of rather pretentious character. Both of these have proved commercially unsuccessful, and neither is, in fact, now employed for the purpose for which it was constructed. The South-Eastern Arcade, at the entrance of the South-Eastern Railway Station, London Bridge, is only remarkable for its unmitigated architectural baldness and poverty. In Paris arcades have obtained much greater popularity than in London. Among the Parisian arcades, the Passage Colbert is one of the most striking, both for its extent and architectural display, towards which last its Rotunda contributes in no small degree.

ARCH. The origin of that species of construction called an arch is unascertained; it cannot be stated with certainty either in what country or at what epoch it was first used. There is good reason to think that, though the arch form was certainly known to the Pelasgic inhabitants of Greece, it was unknown to the Greeks at the time when they produced their most beautiful temples, in the fifth, fourth, and third centuries before the Christian era. No structure answering to the true character of an arch has been found in any part of those works, though many occasions occur in which the application of the arch would have been of great service, and would seem unlikely to have been passed over by an intelligent and ingenious people like the Greeks if they had been acquainted with the principle. The want of the arch would necessarily lead them to contract the intercolumniation, or spaces between the columns, and to the general and frequent adoption of columns as the only mode of supporting a superstructure. But though not appropriated—at least for their sacred buildings—by the Greeks, it is now certain that the arch was known both to the Egyptians and the Assyrians. There are brick arches at Thebes in Egypt, which belong to a very remote epoch, and one long prior to the Greek occupation of that country. Minutoli ('Reise zum Tempel des Jupiter Ammon') has given two specimens of Egyptian arches, one of which is a false and the other a true arch. The first specimen is from the remains at Abydos in Egypt (p. 245), where the roof has the appearance of an arch, but is formed by three horizontal stones, of which that which occupies the centre and lies over the other two is the largest; the three stones are cut under in such a way as to form a semicircle. The true specimens are at Thebes (at least as early as B.C. 1490), on the west side of the river (p. 260), near and behind the building which contains the fragments of the enormous statue. They are circular arches, and formed of four courses of bricks (see pl. 29), and on the walls there are Egyptain paintings and hieroglyphics. (See also Belzoni's 'Plates,' No. 44, and his remarks on the brick arches of Thebes; and also Sir Gardner Wilkinson's 'Egypt and Thebes,' pp. 81 and 126; 'Manners and Customs of the Egyptians,' vol. iii.; and Colour, p. 297.) The stone arches in the Nubian pyramids can hardly perhaps be adduced in proof of the early use of the arch, as these edifices are probably not of very high antiquity (see Cailliaud's 'Plates,' No. 43), though Mr. Hoskins ('Travels in Ethiopia') attributes to the latest of them a date not more recent than that of Cambyses. A stone arch of a date not later than that of Psammeticus has been discovered at Saccara, and another in a tomb near Gizeh. Mr. Layard and M. Place found both round and pointed arches at Nimroud and at Khorsabad, the construction of which shows that the ancient Assyrians were at a very early period sufficiently acquainted with the constructive value of the arch to apply it to a variety of important purposes. In the roofs of the tombs of Lycia, of about the 5th century B.C., the pointed arch occurs. (Fellowes' 'Lycia;' and the works of Forbes and Spratt.) Etruria seems, from the best evidence that can be obtained, to have been the first place in Europe where the arch was employed; and to the Etrurians may be assigned the honour of its earliest applications, as far as our positive and undisputed information goes, in works of an important size and character, in a pointed as well as in the circular form. The great sewer of Rome, commonly called the Cloaca Maxima, is an arched construction, which can hardly be referred to any period in the history of the city with so much probability as to that to which it is assigned by uniform tradition, namely, the age of the Tarquins. But though we may readily admit this early date, we cannot say whether the architects were Roman or Etrurian, though the latter would seem the more probable.

The application of the arched structure is one of the most useful mechanical contrivances ever discovered by man. By means of it, small masses of burnt clay, and conveniently sized pieces of soft and friable sandstone, are made more extensively useful for the economic of Stertinius and Scipio were ornamented with gilded statues; and that of Scipio with two horses also. Whether they precisely resembled the later arches as to their columns, rilievos, and other accessory parts, we cannot say. As far as we can judge from medals, these early triumphal arches consisted of a single arch with a column on each side, without a stylobate; the arch was surmounted by a simple border as a kind of architrave.

Under the emperors these monuments became very numerous, and were overcharged with ornaments. Drusus, the step-son of Augustus, is mentioned as the first who had one raised to him after death, and Livia, the wife of Augustus, was the first woman to whom a similar honour was decreed. Augustus himself had several triumphal arches erected to him, of which the one at Rimini, where the Flaminian Way terminated, still remains, and serves as a gate to the town on the side towards Rome. Another arch, also erected to Augustus, though inferior in beauty to that of Rimini, exists at Susa, at the commencement of the road which leads over Mont Genèvre into France. Of the triumphal arches remaining at Rome, that of Titus is the oldest. It was erected to him after his death by the senate, in memory of his conquest of Judæa. This arch is ornamented with sculptures representing the triumph of the conqueror, and with the ornaments of the temple of Jerusalem which he brought as spoils to Rome. But arches were not erected solely to commemorate victories and conquests; they were also raised in honour of emperors for benefits conferred on their country on some particular occasions: such is the fine arch of Trajan, on the old mole of Ancona. It is of white marble, and chaste in its style; the inscription states that it was raised "by the senate and people of Rome to Trajan, Emperor and Cæsar, son of Nerva, the conqueror of the Germans and Dacians, high pontiff, &c., a most provident prince, for having at his own expense constructed the mole, and thus rendered the access to Italy on this side safer to navigators." Bronze statues of Trajan, of his wife Plotina, and his sister Marciana, were placed on the summit of the arch, but they have been destroyed. Another fine arch in memory of Trajan exists at Benevento; it is



Arch of Constantine.

ornamented with fine rilievos, and is in very good preservation. All these are single arches; but others have two smaller archways, one on each side of the great central one. These are consequently oblong in their shape, and have a heavier appearance than the single arch. Two of these triple arches still exist at Rome, that of Septimius Severus, and that called the arch of Constantine, which we have chosen for our illustration. The view here given is from an original drawing. The arch of Constantine is in the valley at the foot of the Palatine Hill, and near the Colosseum. It is the most complete of all the triumphal arches at Rome; that of Titus has only a central archway, and that of Septimius Severus is more dilapidated, and more encumbered by accumulations of soil. The style of Constantine's arch is also, for the most part, superior to that of the age in which it was executed, as it consists, in great measure, of the materials of a similar monument which had been erected to Trajan. But at the same time, owing to its being chiefly built of old materials, and owing to want of skill in the architect and sculptor, it presents some striking discrepancies of parts, and some specimens of bad taste. The captive Parthians, and other sculptures, which were historically appropriate on the arch of Trajan, are here employed to decorate that of Constantine. Our view indicates an excavation, bounded by a wall of an elliptical form, within which the monument stands. Accumulations of soil had raised the level of the ground nearly up to the bases of the columns; the excavation was made for the purpose of clearing away the rubbish, and the wall with the view of protecting the monument.

The number of marble arches, in honour of emperors and other personages, existing in ancient Rome alone, is stated to have been at one time thirty-six: only five or six are now remaining. Other arches are found in various parts of Italy, at Aquino, Aosta, Pola in Istria, &c.; several in the south of France, of which those of Nîmes and Orange are the best preserved; several in Macedonia, Athens, and in other parts of Greece, all however belonging to the Roman period: several in Syria, and in Barbary, particularly one at Tripoli; and another at Constantina, described by Shaw. In modern times, triumphal arches have been raised in imitation of the Roman ones. Those of the gate St. Denis and the gate St. Martin at Paris were raised in honour of Louis XIV. Bonaparte also had one constructed on the Place du Carousel; it is a triple arch, and has all the heaviness of that particular species of structure. Another, and a much finer one, was begun by his order at Milan, on the opening of the famous road across the Simplon. It was interrupted by the overthrow of the French empire, but has since been completed by order of the Austrian government, under the appellation of the Arch of Peace. In London, two structures of the same kind have been raised of late years, a single arch at Hyde Park Corner, and a triple one of marble originally erected in front of Buckingham palace, but removed on the erection of a new front to that building, to the north-eastern entrance of Hyde Park. On Roman triumphal arches the reader may consult Pitiscus, 'Lexicon Antiquitatum Romanorum,' art. Arcus.

The arch of Augustus at Rimini is 60 feet in height and 27 in depth or thickness; the gateway is 31 feet, being the widest opening among all the ancient arches in Italy. The front is decorated with two Corinthian columns 32 feet high. It is made of Istrian marble.

The arch of Septimius Severus is 61 feet high, 71 feet long, and 22 feet deep. The central archway is 36 feet high, and 22 feet wide. The side arches are 22 feet high and 10 wide.

The arch of Orange, in the south of France, supposed, but upon no certain grounds, to have been erected in honour of Caius Marius, is 70 feet high and 66 long. It is a triple arch.

Arches bearing a great resemblance to triumphal arches, but simpler in form and less ornamented, were also erected at the entrances to the road-way of bridges in Italy, Spain, and France; though comparatively few of them remain. There is one on the bridge erected by Trajan at Alcantara in Spain. Two of very elegant form and in good preservation occur at the bridge of St. Chamas in Provence; and there is a similar double-arch bridge at Saintes in the South of France. These bridge-arches all bear inscriptions recording the date, &c., of their erection.

ARCHÆO'LOGY, literally 'the study of antiquity or ancient things,' from ἀρχαῖος, *ancient*, and λόγος, *a discourse*. Though the term is often used, its meaning in this country has not always been very exactly fixed; but there is nothing properly belonging to it which is not included under the heads of ANTIQUITY and ANTIQUITIES. Like the latter term, the term archæology has been somewhat capriciously confined to the study of Greek and Roman art; but it is now usually employed to express generally the study of all that concerns the early history of any civilised nation or country. The great extension which the study of archæology has received of late years, and is still receiving, has led to the formation of various associations, both in this country and throughout Europe, in order to unite the exertions of all who devote themselves to the study. One of the first of these was the Archæological Institute of Rome, founded in 1829. In our own country, not only are there metropolitan institutes, which have for their object the investigation of the antiquities of the country generally, but in several counties associations have been established, having for their special object the study and preservation of local antiquities.

ARCHBISHOP. For what belongs to the episcopal character and office generally, we refer to the word BISHOP: we mean to confine ourselves in this article to what belongs more peculiarly to the archbishop. For though, in this country, and generally throughout Europe, the archbishop has his own diocese in which he exercises ordinary episcopal functions like any other bishop in his diocese, yet he has a distinct character, having an admitted superiority and a certain jurisdiction over the bishops in his province, who are sometimes called his suffragans, together with some peculiar privileges. This superiority is indicated in the name. The word or syllable *arch* is the Greek element αρχ (which occurs in ἀρχὴ, ἀρχὸς, ἄρχων, &c.), and denotes precedence or authority. It is used extensively throughout ecclesiastical nomenclature, as may be seen in Du Cange's 'Glossary,' where there are the names of many ecclesiastical officers into whose designations this word enters, who were either never introduced into the English Church or have long ceased to exist. Exalted officers of state have sometimes designations into which this word enters, as arch-duke. Why this word was used peculiarly in ecclesiastical affairs rather than any other term denoting superiority is probably to be explained by the fact that the term ἀρχιερεὺς, for chief-priest, occurs in the Greek text of the Christian Scriptures. Patriarch is a less obvious compound of the same class, denoting the chief father, and is used in ecclesiastical nomenclature to denote a bishop who has authority not only over other bishops, but over the whole collected bishops of divers kingdoms or states; it is analogous in signification to the word *pope* (papa), a bishop to whom this extended superintendence is attributed.

Whatever might be the precise functions of the episcopus (ἐπίσκοπος, bishop), the term itself occurs in the writings of St. Paul, Phil. i. 1, 1 Tim. iii. 2, and elsewhere; but the word ἀρχιεπίσκοπος, or archbishop, is not found till about or after the 4th century. Cyrillus Archiepiscopus Hierosolymitanorum, and Celestinus Archiepiscopus Romanorum, occur under these designations in the proceedings of the Council held at Ephesus, A.D. 431. Other terms by which an archbishop is sometimes designated are primate and metropolitan. The first of these is formed from the Latin word *primus*, 'the first,' and denotes simple precedency, the first among the bishops. The latter is a Greek term, which rendered literally into English would be *the man of the mother-city*, that is, the bishop who resides in that city where is the mother church of all the other churches within the province or district in which he is the metropolitan.

The term metropolitan, when thus analysed, points out to us the origin of whatever real distinction there is between bishop and archbishop, or, in other words, the cause of that elevation which is given to the archbishop above the bishops in his province, when it is not to be attributed to mere personal assumption, or to be regarded only as an unmeaning title. The way in which Christianity became extended over Europe was this: an establishment was gained by some zealous preacher in some one city; there he built a church, performed in it the rites of Christianity, and lived surrounded by a company of clerks engaged in the same design and moving according to his directions. From this central point, these persons were sent from time to time into the country around for the purpose of promoting the reception of Christianity, and thus other churches became founded, offspring or children, to use a very natural figure, of the church whence the missionaries were sent forth. When one of these subordinate missionaries had gained an establishment in one of the more considerable cities, remote from the city in which the original church was seated, there was a convenience in conferring upon him the functions of a bishop; and the leading design, the extension of Christianity, was more effectually answered than by reserving all the episcopal powers in the hands of the person who presided in the mother church. Thus other centres became fixed; other bishoprics established; and as the prelate who presided in the first of these churches was still one to whom precedence at least was due, and who still retained in his hands some superintendence over the newer bishops, *archbishop* became a suitable designation. Thus, in England, when there was that new beginning of Christianity in the time of Pope Gregory, Augustine, the chief person of the mission, gained an early establishment at Canterbury, the capital of the kingdom of Kent, through the favour of King Ethelbert. There, in this second conversion, as it may be called, the first Christian church was established, and thence the persons were sent out who at length Christianised the whole of the southern part of England. Paulinus, in like manner, a few years later, gained a similar establishment in the kingdom of Northumbria, through the zeal of King Edwin, who received Christianity, and built him a church at York, one of his royal cities, which may be regarded as the chief city of Edwin's kingdom. From York the light of Christianity was diffused over the northern parts of England, as from Canterbury over the southern. It seems to have been the peculiar diligence and dignity of Paulinus which procured for him the title of archbishop, and gave him a province, instead of a diocese only, as was the case with the other members of the Augustinian mission. This was done by special act, under the authority, it is said, of Justus, an early successor of Augustine. But the precedence of the real English metropolitan is acknowledged in two circumstances: in the style, the one being a primate of England, and the other the primate of all England; and in the rank, precedence being always given to the Archbishop of Canterbury, and the Lord Chancellor of England being interposed in processions between the two archbishops.

Under the later empire the name metropolis was applied to various cities of Asia and conferred on them as a title of rank. The emperors Theodosius and Valentinian conferred on Berytus in Phœnicia the name and rank of a metropolis "for many and sufficient reasons." ('Cod.' xi. tit. 22 (21).) Accordingly the bishop of a metropolis was called metropolitan (μητροπολίτης), and the bishop of a city which was under a metropolis was simply called bishop. All the bishops, both metropolitan and others, were subject to the archbishop and patriarch of Constantinople, who received his instructions in ecclesiastical matters from the emperor. ('Cod.' i. tit. 3, s. 42, 43.)

The precise amount of superintendence and control preserved by the archbishops over the bishops in their respective provinces, does not seem to be very accurately defined. Yet if any bishop introduces irregularities into his diocese, or is guilty of scandalous immoralities, the archbishop of the province may, as it seems, inquire, call to account, and punish. He may, it is said, deprive. In 1822 the archbishop of Armagh deposed the bishop of Clogher from his bishopric. In disputes between a diocesan and his clergy an appeal lies to the archbishop of the province in all cases except disputes respecting curates' stipends. (1 & 2 Vict. c. 106.) Rolle, a good authority, says that the archbishop may appoint a co-adjutor to one of his suffragans who is infirm or incapable. This right is now confirmed by 6 & 7 Vict. c. 62, intituled 'An Act to provide for the Performance of the Episcopal Functions in case of the Incapacity of any Bishop or Archbishop.'

An archbishop has a right to name one of his clerks or chaplains to be provided for by every bishop whom he consecrates. The present practice is for the bishop whom he consecrates, to make over by deed to the archbishop, his executors and assigns, the next presentation of such benefice or dignity which is at the bishop's disposal within his see, as the archbishop may choose. This deed only binds the bishop who grants, and, therefore, if a bishop dies before the option is vacant, the archbishop must make a new option when he consecrates a new bishop. If the archbishop dies before the benefice or dignity is vacant, the next presentation goes to his executors or assigns according to the terms of the grant.

The archbishop also nominates to the benefices or dignities which are at the disposal of the bishops in his province, if not filled up within six months from the time of the avoidance. During the vacancy of a see, he is the guardian of the spiritualities.

Certain of the bishops are nominally officers in the Cathedral of Canterbury, or in the household of the archbishop. The archbishop has also certain honorary distinctions; he has in his style the phrase "by Divine providence," but the bishop's style runs "by Divine permission;" and while the bishop is only installed, the archbishop is enthroned.

The archbishops may nominate eight clerks each to be their chaplains. The archbishop of Canterbury claims the right of placing the crown upon the head of a king at his coronation; and the archbishop of York claims to perform the same office for the queen consort. The archbishop of Canterbury is the chief medium of communication between the clergy and the king, and is consulted by the king's ministers in all affairs touching the ecclesiastical part of the constitution; and he generally delivers in parliament what, when unanimous, are the sentiments of the bench. The two archbishops have precedence of all temporal peers, except those of the blood-royal; and except that the lord chancellor has place between the two archbishops. Before the Reformation, the archbishop of Canterbury occupied a very elevated station with reference to the whole church, having at general councils the precedence of all archbishops, and being regarded somewhat in the light of a patriarch, presiding, as he was supposed to do, over the several kingdoms of England, Wales, Scotland, and Ireland.

The province of the archbishop of York consists of the six northern counties, with Cheshire and Nottinghamshire; to these were added, by Act of Parliament in the time of Henry VIII., the Isle of Man: in this province he has six suffragans, the bishop of Sodor and Man, the bishop of Durham, the only see in his province of Saxon foundation, and the bishops of Carlisle, Chester, Ripon, and Manchester. Of these, the bishopric of Carlisle was founded by king Henry I. in the latter part of his reign, and the bishopric of Chester by king Henry VIII.; so thinly scattered was the seed of Christianity over the northern parts of the kingdom in the Saxon times. The rest of the kingdom forms the province of the archbishop of Canterbury, in which there are twelve bishoprics of Saxon foundation; the bishopric of Ely, founded by Henry I.; the bishoprics of Bristol, Gloucester, Oxford, and Peterborough, founded by Henry VIII.; and the four Welsh bishoprics, of which St. David's and Llandaff exhibit a catalogue of bishops running back far beyond the times of St. Augustine. The twelve English bishoprics of Saxon foundation are London, Winchester, Rochester, Chichester, Salisbury, Exeter, Bath and Wells, Worcester, Hereford, Lichfield and Coventry, Lincoln, and Norwich. The dioceses of the two English archbishops, or the districts in which they have ordinary episcopal functions to perform, are, for Canterbury, the greater part of the county of Kent, a portion of that county forming the diocese of Rochester, a number of parishes distinct from each other, and called Peculiars, in the county of Sussex, with small districts in other dioceses, particularly London, which belonging in some form to the archbishop, acknowledge no inferior episcopal authority. The diocese of the archbishop of York consists of a great portion of the county of York, and the whole county of Nottingham, with some detached districts.

Lives of all the archbishops and bishops of England and Wales are to be found in an old book entitled 'De Præsulibus Angliæ Commentarius.' It is a work of great research and distinguished merit. The author was Francis Godwin, or Goodwin, bishop of Llandaff, and it was first published in 1616. A new edition of it, or rather the matter of which it consists, translated and recast, with a continuation to the present time, would form a useful addition to our literature. There is also an 8vo. volume, published in 1720, by John le Neve, containing lives of all the Protestant archbishops, but written in a dry and uninteresting manner. Of particular lives there are many, by Strype and others; many of the persons who have held this high dignity having been distinguished by eminent personal qualities, as well as by the exalted station they have occupied.

St. Andrew's is to Scotland what Canterbury is to England: and while the episcopal form and order of the church existed in that country, it was the seat of the archbishop, though till 1470, when the pope granted him the title, he was known only as the Episcopus Maximus Scotiæ. In 1491, the bishop of Glasgow obtained the title of archbishop, and had three bishops placed as suffragans under him.

In Ireland there are two archbishoprics, Armagh and Dublin; two, Tuam and Cashel, having been, by the Act 3 & 4 Will. IV. c. 37, reduced to bishoprics. Armagh, of which the archbishop is styled Primate of all Ireland, has five suffragan bishops, Meath, Tuam, Derry, Down, and Kilmore; the archbishop of Dublin is styled Primate of Ireland, and has also five suffragan bishops, Ossory, Cashel, Cork, Killaloe, and Limerick. Catalogues of the archbishops of Ireland and Scotland may be found in that useful book for ready reference the 'Political Register,' by Robert Beatson, Esq.

To enumerate all the prelates throughout Christendom, to whom the rank and office of archbishop are attributed, would extend this article to an unreasonable length. The principle exists in all Catholic countries, that there shall be certain bishops who have a superiority over the rest, forming the persons next in dignity to the great pastor pastorum of the church, the pope. The extent of the provinces belonging to each varies, for these ecclesiastical distributions of kingdoms were not made with foresight, and on a regular plan, but followed the accidents which attended the early fortunes of the Christian doctrine. In Germany, some of the archbishops attained no small portion of political independence and power. Three of them, namely, those of Treves, Cologne, and Mentz, were electors of the empire. In France, under the old régime, there were eighteen archbishoprics, all of which, except Cambray, claimed to have been founded in the 2nd, 3rd, and 4th centuries; the foundation of the archbishopric of Cambray was referred to the 6th century. The French have a very large and splendid work, entitled 'Gallia Christiana,' containing an ample history of each province, and of the several subordinate sees comprehended in it, and also of the abbeys and other religious foundations, with lives of all the prelates drawn up with the most critical exactness.

The word *suffragan*, used in this article, may require some explanation. A suffragan, in the more ordinary sense of the term, is a kind of titular bishop, a person appointed to assist the bishop in the discharge of episcopal duties; and among the reforms meditated at the close of the reign of King Henry VIII., was the introduction of a considerable number of suffragan bishops of this class, and some persons were actually consecrated. But every bishop within his province is sometimes spoken of as a suffragan of the archbishop, being originally, in fact, little more. Questions have been raised respecting the origin of the word suffragan, which is by some supposed to be connected with *suffrages* or votes, as if the bishops were the voters in ecclesiastical assemblies; but more probably, if connected with suffrages at all, the term has a reference to their claiming to vote in the election of the archbishop. A great question respecting the right of election of an Archbishop of Canterbury, between the suffragans of his province and the canons of Canterbury, arose in the time of King John, and is a principal occurrence in the contest which he waged with the pope and the church.

ARCHDEACON. In contemplating the character and office of the bishop in the early ages of the church, we are not to regard him as a solitary person acting alone and without advice. He had a species of clerical council around him, persons who lived a kind of collegiate life in buildings attached to the great cathedral church, each of whom, or at least several of whom, possessed distinct offices, such as those of chancellor, treasurer, precentor, and the like. These persons are now often called canons; but the most general name by which they are to be known, as the institution existed in remote times, is that of deacon, a term of which dean is a contraction. Deacon appears to come from the Greek term *διάκονος*, the name of that officer in the church of whose appointment we have an account in Acts, vi. 3—6. To one of these deacons precedence was given, and no doubt some species of superintendence or control, and to him the title of *archdeacon* was assigned.

In the name there is no indication of any peculiar employment. What now belongs to the archdeacon was anciently performed by the officer in the bishop's court called the chorepiscopus. The chorepiscopus (*Χωρεπίσκοπος*) was the bishop's deputy or vicar in small towns and country places, in which he discharged the minor episcopal functions. He might be of episcopal rank or not (Ducange, 'Glossarium'). The chorepiscopus is mentioned in a Constitution of Justinian. ('Cod.' i. tit. 3, s. 41 (42).) The manner in which the archdeacon usurped upon this obsolete officer and attracted to himself the functions which belonged to him, is supposed to have been this:—being near the bishop and much trusted by him, the archdeacon was often employed by the bishop to visit distant parts of the diocese, especially when the bishop required particular and authentic information, and to report to the bishop the actual state of things. Hence deacons were spoken of by very early Christian writers as being the *bishop's eye;* and from this power of inspection and report the transition was easy to the delegation, to one of the deacons, of a portion of episcopal authority, and empowering him to proceed to reform and redress, as well as to observe and report.

If this is a just account of the origin of the archdeacon's power, it is manifest that originally the power would be extended over the whole of a diocese; but at present it is confined within certain limits. In England, according to the 'Valor Ecclesiasticus' of King Henry VIII., there are 54 archdeaconries, or districts through which the visitorial and corrective power of an archdeacon extends. Godolphin and Blackstone state that there were 60 archdeaconries: the number has since been increased, and there are now above 60 in England and Wales. Seven new archdeaconries were erected by 6 & 7 Will. IV. c. 97. These are the archdeaconries of Bristol, Maidstone, Monmouth, Westmoreland, Manchester, Lancaster, and Craven; and archidiaconal power was given by the same act to the dean of Rochester, in that part of Kent which is in the diocese of Rochester.

This distribution of the dioceses into archdeaconries cannot be assigned to any certain period, but the common opinion is, that it was made some time after the Conquest. It is said that Stephen Langton, archbishop of Canterbury, was the first English bishop who established an archdeacon in his diocese, about A.D. 1075. The office of archdeacon is mentioned in a charter of William the Conqueror. (Phillimore.) The bishops had baronies, and were tied by the Constitutions of Clarendon to a strict attendance upon the king in his great council, and they were consequently obliged to delegate their episcopal powers. Each archidiaconal district was assigned to its own archdeacon, with the same precision as other and larger districts are assigned to the bishops and archbishops; and the archdeacons were entitled to certain annual payments, under the name of procurations, from the benefices within their archdeaconries. The act already cited (6 & 7 Will. IV. c. 97) directed a new arrangement of all existing deaneries and archdeaconries, so that every parish and extra-parochial place shall be within a rural deanery, and every deanery within an archdeaconry, and that no archdeaconry extend out of the diocese.

As the archdeacon in ancient times intruded upon the chorepiscopus, so in recent times he has extinguished the authority and destroyed almost the name of another officer of the church, namely, the rural dean.

The archdeaconries are still subdivided into deaneries, and it is usual for the archdeacon, when he holds his visitations, to summon the clergy of each deanery to meet him at the chief town of the deanery. Formerly, over each of the deaneries a substantive officer, called a dean, presided, whose duty it was to observe and report, if he had not even power to correct and reform; but the office has been laid aside in some dioceses, though in others it has been re-established. But where it has been superseded, the duties are discharged by the archdeacon. Though the office of rural dean has been found extremely useful, no emolument whatever is attached to it.

Archdeacons must have been six full years in priest's orders (§ 27, 3 & 4 Vict. c. 27), and they are appointed by the respective bishops; they are inducted by being placed in a stall in the cathedral by the dean and chapter. By virtue of this *locus in choro* a *quare impedit* lies for an archdeaconry. (Phillimore.) The duty of archdeacons now is to visit their archdeaconries from time to time: to see that the churches, and especially the chancel, are kept in repair, and that everything is done conformably to the canons and consistently with the decent performance of public worship; and to receive presentations from the churchwardens of matter of public scandal. The visitation of the archdeacon may be held yearly, but he must of necessity have his triennial visitation. Archdeacons may hold courts within their archdeaconries, in which they may hear ecclesiastical causes, but an appeal lies to the superior court of the bishop. (24 Hen. VIII. c. 12.) By § 3 of 3 & 4 Vict. c. 86, the archdeacon may be appointed one of the assessors of the bishop's court in hearing proceedings against a clergyman. The judge of the archdeacon's court, when he does not preside himself, is called the Official. Sometimes the archdeacon has a peculiar jurisdiction, in which case his jurisdiction is independent of that of the bishop of the diocese, and an appeal lies to the archbishop. [PECULIAR.] By 6 & 7 Will. IV. c. 97, § 19, it is enacted that all archdeacons throughout England and Wales shall have and exercise full and equal jurisdiction within their respective archdeaconries, any usage to the contrary notwithstanding.

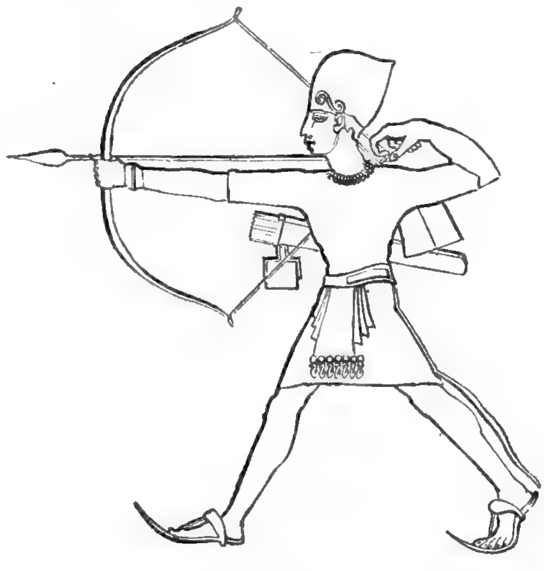
In the revenue attached to the office of archdeacon, we see the inconvenience which attends fixed money payments in connection with offices which are designed to have perpetual endurance. It arises chiefly from the payments by the incumbents. These payments originally bore no contemptible ratio to the whole value of the benefice, and formed a sufficient income for an active and useful officer of the church; but now, by the great change which has taken place in the value of money, the payments are little more than nominal, and the whole income of the archdeacons as such is very inconsiderable. The office, therefore, is generally held by persons who have also benefices or other preferment in the church. There have been in recent times cases where archdeacons have held prebends of cathedrals in other dioceses than that in which their jurisdiction was situated; and also instances in which they have had no cathedral preferment. The 1 & 2 Vict. c. 106, § 124, specially exempts archdeacons from the general operation of the Act, by permitting two benefices to be held with an archdeaconry. An archdeacon is said to be a corporation sole. Among the recent Acts which affect archdeacons the most important are 1 & 2 Vict. c. 106; 3 & 4 Vict. c. 113; and 4 & 5 Vict. c. 39.

Catalogues of the English archdeacons may be found in a book entitled 'Fasti Ecclesiæ Anglicanæ,' by John le Neve. Archdeaconries have been established in some, if not in all, of the dioceses of the new colonial bishops.

ARCHERY, the art of shooting with a bow and arrow. With respect to the origin of archery, the use of the bow may be traced to the remotest antiquity, and it occurs in the history of many different nations; but some people, the ancient Britons for instance, did not use the bow. The first notice which we find of it is in Genesis (xxi. 20), where it is said that Ishmael the son of Abraham "dwelt in the wilderness and became an archer:" a bow-shot too is mentioned in an earlier verse of the same chapter as a measure of distance. In the Greek mythology we find Apollo armed with the bow and arrow (Homer, 'Iliad,' i. 45), and Hercules also, as described in the 'Odyssey' (xi. 606). The use of these weapons we may therefore conclude to be of very high antiquity among the Greeks. In the war of Troy, the main force of the Greeks appears to have consisted of soldiers who had heavy defensive armour; but the soldiers of Philoctetes were archers. The Cretans maintained their reputation as skilful bowmen to a late period in their history; and we find Meriones, the companion of the Cretan king Idomeneus, carrying off the prize from Teucer himself ('Iliad,' xxiii. 882). Teucer, the brother of Ajax, who came from the island of Salamis, excelled in the use of the bow and arrow, which appear however to have been considered less honourable weapons than the spear and sword. Ulysses in the 'Iliad' fights with the spear and sword, but in the 'Odyssey' we find the strength of the suitors tested by the bow which Ulysses had left at home, and which he afterwards uses against his domestic enemies.

In the later times of Greece, archers formed a part of the light-armed troops, in the same manner as the Sagitarii among the Romans afterwards formed a part of the Velites. Procopius records it as a great improvement when the Roman auxiliaries were instructed to draw the right hand to the ear. But the practice itself is of much greater antiquity, as we see in the representations of the sea-fight on the walls of Medinet-Habou, at Thebes in Egypt. ('Egypte, Antiq.,' vol. ii.)

Representations of archers frequently occur in the sculptured slates found at Khorsabad and Nineveh (Botta and Layard, *passim*); indeed the bow seems to have been a common weapon in the Assyrian armies. Archery was also, as we learn from Procopius, the fashion with the ancient Persians.



Egyptian Archer.

The time when the use of the long-bow commenced in England, as a military weapon, is unknown. That which the Normans used at the battle of Hastings was the arbalest or cross-bow. In the reign of Henry II. we find several facts recorded which show the continuance of the use of the cross-bow; and in that of Henry III. we find cross-bowmen forming the vanguard of the army. As a military weapon of England, the arbalest, in all probability, was last used at the battle of Bosworth in 1485, though as late as 1572 Queen Elizabeth engaged by treaty to supply the King of France with 6000 men, armed partly with long, partly with cross-bows. It was also used on the Continent in the wars of the 16th century.

From the reign of Edward II. the mention of the long-bow becomes frequent in our history. At Crécy, at Poictiers, and at Agincourt, as well as in several battles which were gained over the Scotch, the victory is ascribed to the English bowmen; and it is particularly noticed that at Crécy the rain, which had slackened the strings of the Genoese cross-bows, had not weakened the effect of the long-bows which our countrymen used. Edward III. enjoined the use of the long-bow in two precepts addressed to the sheriffs of counties; and in the reign of Richard II. an act was passed to compel all servants to shoot with it on Sundays and holidays. By the 7 Hen. IV. the heads of arrows were to be well boiled or brazed, and hardened at the points with steel; all heads otherwise manufactured were to be forfeited, and the makers imprisoned: all arrow-heads, moreover, were to be marked with the maker's name. Henry V. ordered the sheriffs of several counties to procure feathers from the wings of geese, picking six from each goose. Two feathers in an arrow were to be white, and one brown or grey; and this difference in colour informed the archer in an instant how to place the arrow. In the time of Edward IV. an Act passed ordaining that every Englishman should have a bow of his own height; and butts were ordered to be constructed in every township for the inhabitants to shoot at on feast days; and if any neglected to use his bow, the penalty of a halfpenny was incurred. An Act, 1 Richard III., complains, that by the seditious confederacy of Lombards using divers ports of this realm, bow-staves were raised to an outrageous price; that is to say, to 8*l.* a hundred, whereas they were wont to be sold at 40*s.* This Act provided that ten bow-staves should be imported with every butt of malmsey or Tyre wines, brought by the merchants trading from Venice to England, under a penalty of 13*s.* 4*d.* for every butt of the said wines in case of neglect. By 6 Hen. VIII. c. 2, all male servants were to provide themselves with one bow and four arrows, which their master was to pay for, stopping the purchase-money out of their wages. Another statute, enjoining the use of archery more extensively, was passed in 33 Henry VIII. It ordained that every man under sixty, except spiritual men, justices, &c., should use shooting with the long-bow, and have a bow and arrows continually in his house: that he should provide bows and arrows for his servants and children; that every servant, above seventeen and under sixty years of age, should pay 6*s.* 8*d.* if he was without a bow and arrows for one month. The inhabitants of every city, town, and place were to erect butts, and practice shooting on holidays, and at every other convenient time. Latimer, in one of his sermons before King Edward VI., published in 1549, enforced the practice of archery from the pulpit. "Men of England in times past," he says, "when they would exercise themselves (for we must needs have some recreation, our bodies cannot endure without some exercise), they were wont to go abroad in the fields of shooting, but now it is turned into glosing, gulling, and whoring within the house. The art of shooting hath been in times past much esteemed in this realm; it is a gift of God that he hath given us to excel all other nations withal; it hath been God's instrument whereby he hath given us many victories against our enemies. But now we have taken up whoring in towns instead of shooting in the fields. A wondrous thing, that so excellent a gift of God should be so little esteemed! I desire you, my lords, even as ye love the honour and glory of God, and intend to remove his indignation, let there be sent forth some proclamation, some sharp proclamation to the justices of peace; for they do not their duty. Justices now be no justices; there be many good Acts made for this matter already. Charge them upon their allegiance that this singular benefit of God may be practised . . . . for they be negligent in executing these laws of shooting. In my time, my poor father was as diligent to teach me to shoot, as to learn me any other thing, and so I think other men did their children. He taught me how to draw, how to lay my body in my bow, and not to draw with strength of arms as other nations do, but with strength of the body. I had my bows bought me according to my age and strength; as I increased in them, so my bows were made bigger and bigger; for men shall never shoot well except they be brought up in it. It is a godly art, a wholesome kind of exercise, and much commended in physic." Holinshed reports that Henry VIII. shot as well as any of his guards.

The encouragement thus given to shooting with the long-bow caused archery to become a fashionable amusement after the bow had ceased to be used as an instrument of war. Edward VI. was fond of this exercise; and there seems every reason to believe that it was practised by King Charles I. This monarch issued a proclamation in the eighth year of his reign, to prevent the fields near London from being so inclosed as "to interrupt the necessary and profitable exercise of shooting." He is also represented in the frontispiece of Markham's 'Art of Archery,' 1634, in the dress and attitude of a bowman. Public exhibitions of shooting with the bow were continued in the reigns of King Charles II. and King James II.; and an archers' division, at least till within the present century, formed a branch of the Artillery Company.

The most important society of this kind now existing is "The Royal Company of Archers, the King's body-guard of Scotland." The exact time of its institution is unknown, but it is referred by the Scottish antiquaries to the reign of their James I., when a commission being appointed to oversee and enforce the exercise of archery in different counties of that kingdom, the most expert bowmen were selected from the mass of those raised, to form a body-guard for the king on perilous occasions, and are stated to have conducted themselves with skill, loyalty, and courage. The rank of the King's body-guard for Scotland was understood from tradition to be vested in the Royal Company, and they accordingly claimed the honour of acting in this capacity to his majesty King George IV. on the occasion of his visit to Scotland in 1822. They attended his majesty at court and on all state ceremonies during his residence in Scotland, and accompanied him on his visit to Hopetoun House, from whence he embarked for London. The Royal Company of Archers now forms part of the royal household in Scotland; it has a captain-general, four lieutenants-general, four majors-general, four ensigns-general, and fifteen brigadiers-general, offices held by persons of distinguished rank.

From their own minutes, still extant, it appears that an Act of the privy council of Scotland was passed in 1677, conferring on this body the name and title of "His Majesty's Company of Archers," and granting a sum of money for a piece of plate to be shot for as a prize. No permanent king's prize, however, was established till 1788, when a sum of money was granted by King George III. to be shot for annually, with which a piece of plate was to be purchased.

During the Revolution of 1688 the Royal Company were opposed to the principles then espoused, and were all but suppressed. On Queen Anne's succession they were revived, and in 1703 received a royal charter confirming all their former rights and privileges, and conferring others upon them. The affairs of the Royal Company, which now consists of about 500 members, are managed by a council of seven, who are chosen annually by the members at large, and in whom is vested the power of receiving or rejecting candidates for admission, and of appointing the officers of the company civil and military. The field uniform of the Royal Company is of dark green cloth, faced with black braiding, with a narrow stripe of crimson velvet in the centre. The hat is of the same colour, with a handsome medallion in front, and a plume of black feathers. They have two standards. New colours, as well as a confirmation of the Royal Company to be the king's body-guard for Scotland, were given to them by King William IV.

Towards the end of the last century, the revival of archery as a general amusement was attempted, under the patronage of the then Prince of Wales; and at that time, and subsequently, numerous societies of archers were formed, many of which printed their rules and orders. Archery-meetings are still held in various parts of the country, and ladies are frequently competitors for the honorary prizes given.

The distance to which an arrow could be shot from the long-bow depended much upon the strength and art of the bowman; but, in general, the distance was reckoned from eleven to twelve score yards. In 1794, the Turkish ambassador's secretary, in a field behind Bedford Square, near the Toxophilite ground, with a Turkish bow and arrow, shot 415 yards partly against the wind, and 482 yards with the wind. He said that the then Grand Sultan shot 500 yards, which was the greatest performance of the modern Turks; but that pillars stood on a plain near Constantinople, commemorating ancient distances about 800 yards. The Baron de Tott says, in his 'Memoirs,' Paris, 1785, tom. ii. p. 107, "Nearly all the Turkish emperors have had the vanity of pretending to this kind of celebrity."

Ascham has enumerated fifteen sorts of wood, of which arrows were made in England in his time, namely, brazell, turkiewood, fusticke, sugercheste, hardbeame, byrche, ashe, oak, service-tree, alder, blackthorn, beach, elder, aspe, and salow. Of these, asp and ash were preferred to the rest, the one for target-shooting, the other for war. Whistling arrows have been once or twice found on fields of battle of the time of Edward VI. They were chiefly used, it is believed, for giving signals in the night. The Chinese have used whistling arrows from time immemorial. The arrows shot from cross-bows were called quarrels, or bolts. They were usually headed with a large square pyramid of iron; but had sometimes other forms given to them.

(Ascham's *Toxophilus*, 1515; Markham's *Art of Archerie*, 1634; Barrington's *Observations on the Practice of Archery in England*, printed in the 'Archæologia;' and the late Mrs. Banks's *Manuscript Collections on Archery*, preserved in the British Museum.)

ARCHES, COURT OF, is the supreme court of appeal in the archbishopric of Canterbury. It derives its name from having formerly been held in the church of St. Mary le Bow (*de Arcubus*), from which place it was removed about 1567 to the Common Hall of Doctors' Commons, where it has since been held. The judge of the court is termed Official Principal of the Court of Arches, or more commonly Dean of the Arches. This court has ordinary jurisdiction in all spiritual causes, other than those prosecuted under the Church Discipline Act, 3 & 4 Vict. c. 86, and the statute 1 & 2 Vict. c. 106, s. 98, arising within the parish of St. Mary le Bow and twelve other parishes, which are called a deanery, and are exempt from the authority of the Bishop of London. It has also a general appellate jurisdiction in ecclesiastical causes, other than those above referred to, arising within the province of Canterbury. Extensive as this jurisdiction appears to be, the court has now practically little or nothing to do, as the ecclesiastical offenders whose correction formerly constituted the business of the court, can now be prosecuted only under the provisions of the statutes above mentioned. (Blackst. 'Comm.' Mr. Kerr's ed., vol. i. p. 384.)

The Dean of the Arches for the time being is president of the College of Doctors of Law, who had, until recently, the exclusive privilege of practising in the Ecclesiastical and Admiralty Courts, and who received their admission in the Arches Court. The statute transferring the testamentary jurisdiction of the Ecclesiastical Courts to the Crown (20 & 21 Vict. c. 77) has provided for the dissolution of the College of Doctors of Law; and that, and the statute 20 & 21 Vict. c. 85, have thrown open the practice in the Probate and Divorce Courts to the bar and to the attorneys. The Dean of the Arches, who is the deputy of the archbishop, has always been selected from the College of Doctors of Law. There is no salary attached to the office of judge; and his income arising from fees, as also that of the registrar, is very small.

The court of the province of York, which corresponds to the Court of Arches, is called the Chancery Court of York. The number of advocates practising in this court has never exceeded four. They are admitted by fiat of the archbishop, directed to his chancellor, and have power to practise in all the courts of the archbishop; but it is not necessary that they should be Doctors of Civil Law. [ECCLESIASTICAL COURTS.]

ARCHIATER (in Greek ἀρχίατρος), an honorary distinction conferred on physicians in the times of the Roman emperors, and still employed in some of the Continental countries. Physicians generally occupied a very subordinate station in Rome during the republican period: in fact, no well-educated medical men existed among the Romans at that time; and the Greek physicians who went to Rome were not at first favourably received. Julius Cæsar at length bestowed the rights of Roman citizenship on the foreign physicians practising at Rome; and the Emperor Augustus, after his recovery from a dangerous illness, not only conferred on his own physician, Antonius Musa, the honours of knighthood, but is said to have exempted all physicians from the payment of taxes and other public burdens. The Emperor Nero first gave the title Archiater (chief of the physicians) to his medical attendant, Andromachus the elder, well known as the inventor of a celebrated compound preparation called Theriaca. It is probable that the emperor only intended to express, by this title, the consideration in which he held his own physician; but it appears that, soon afterwards, the Archiatri were charged with some kind of superintendence over the medical profession. Thus Galen says of Andromachus: "It appears to me that he was appointed by the emperor at that time to reign over us;" and we also find that the word *Archiater* was translated into Latin by the words *superpositus medicorum*, 'superintendent of the physicians.' At a later period, however, the rank or office of the Archiatri seems to have undergone some change; and we find two classes of them distinguished, namely, the Archiatri of cities, and those of the court. The first law regarding the Archiatri of cities (*Archiatri populares*) was given by Antoninus Pius. He ordered each smaller town to have five, the larger seven, and the largest cities to have ten physicians, distinguished by the above name, and wholly exempted from the payment of taxes and public burdens: thus it appears that the exemption of all practitioners, if it ever existed, was found too extensive a privilege. At Rome, there were fourteen Archiatri appointed for the different districts of the city, besides one for the vestal virgins, and another for the gymnasia: they were elected by the citizens and proprietors, and approved by their colleagues. In later times, the Archiatri of a higher rank appear to have had the sanction of the emperor; and it is not improbable that some sort of examination was also requisite for their admission. Besides enjoying the privileges alluded to, the Archiatri derived from the towns certain remunerations in kind (*annonaria commoda*), as well as salaries. It was their business to treat poor patients gratuitously, but in treating other persons they were authorised to take fees like their professional brethren. They formed medical committees or colleges in each city, and superintended the public health, and the state of the medical profession, and they also taught the principles and practice of medicine. Thus a decree of Constantine the Great says, "We order rewards and salaries to be given to them, that they may the more readily imbue many pupils with liberal studies and the said arts." There is a variety of laws relative to the Archiatri, showing that the Romans regarded the members of the medical profession as deserving and requiring the attention and protecting care of government. The physicians attached to the imperial court took the title of Archiatri of the palace, and also formed a corporation, with certain rights, privileges, and distinctions of rank, which became more important during the reigns of the later emperors, when strict rules of precedency were established for all persons connected with the court and government. The Count of the Archiatri was a *vir spectabilis*, and equal in rank to the dukes and to the vicars of the emperor.

In modern times, the name of Archiater has, in imitation of the ancient fashion, sometimes been assumed by physicians holding public appointments in cities, but more frequently by the physicians of kings and princes. In Sweden and Denmark, however, the dignity of Archiater still exists, as the highest honour conferred on medical men: in Sweden there are only two Archiatri, who act as physicians to the king.

ARCHIL, *orchil, litmus*, or *tournsole*, is a blue dye procured from the *Rocella tinctoria* and *Ceanora tartarea*, which are lichens growing abundantly in the Canary and Cape Verd islands. The colouring matter of these plants appears to be a peculiar vegetable principle which has been called *erythrine*. It may be extracted either by means of alcohol or ammonia, but the latter is employed by those who manufacture the colour, which is generally sold in small flat pieces, and known by the name of litmus.

The blue colour of litmus is soluble in water and in alcohol. A strong infusion, when looked at in mass, is purple; but a diluted one is of a pure blue colour by day-light, and red by candle-light. Acids redden the colour of litmus, and this effect is produced even by the weakest of them, as carbonic acid and sulphuretted hydrogen; when mixed with the latter, and kept for some days in a well-stopped bottle, the colour is destroyed; but by exposure to the air, or by boiling, the colour is restored. Sulphureous acid and the hypo-sulphites also bleach litmus. These effects appear to be the result of deoxidisement, for the blue colour is restored by the absorption of oxygen.

Archil is brought to market in three states—violet-red liquid paste, blue lumps, and powder. It is employed by chemists to ascertain the presence of acids in solution, because it has the property of changing from blue to red by contact with acids; and it also detects alkalies, by restoring the blue which had been changed by acids. Archil is never used alone as a dye, on account of its want of permanence. It is however employed for the purpose of deepening and improving the tints of other dyes, and it imparts a bloom which it is difficult to obtain from other substances. Liquid archil is much used for staining wood, and tinting silk stockings.

M. Clenchard, a French chemist, in 1850 patented a mode of using archil in the dyeing and printing of woollen and silk goods, in which the archil is combined with alkalies and lime, and applied to the woven material with a more direct action than in the ordinary mode of its use.

Archil communicates a beautiful violet colour to marble.

The island of Teneriffe yields a great portion of the lichen from which archil is prepared.

ARCHIL. [LICHENS, COLOURING MATTERS OF.]

ARCHIMANDRITE, the title of a dignitary in the monastic orders of the Greek church, answering to that of Father Provincial among the monks and friars of the Roman Catholic Church. The archimandrite is a superior abbot, having under his jurisdiction several convents of the same district or province. The Russian Church, which is a branch of the Greek, has its archimandrites, as well as the Greek Church in other places where that religion is recognised.

ARCHIMEDIAN SCREW. A machine frequently used for the purpose of raising water, when the height to which the water is to be raised is not considerable; for laying in the foundations of bridges, and for draining the marsh lands of the low countries, this machine appears to be peculiarly adapted, and it is principally in the Netherlands that it may be seen at work.

In ordinary Archimedian screws three threads are formed on a central core, enclosed in an exterior envelope; the exterior diameter of the threads being usually made from 1 foot 2 inches to 2 feet 4 inches, and about three times the diameter of the core; and the length of the screw is made from twelve to eighteen times the external diameter of the thread, whatever that may be. These threads and core are enclosed in a water-tight case, and the water rises, by following their movement, towards the upper end of the screw; for the inclination of the threads upon the axis, and their uninterrupted course, enables the water which enters in the continually turning tube to flow over the curved surface formed by the threads, as it would do on an inclined plane. The inclination of the axis with the horizon is usually made to vary between 35° and 45°; and the screw works the most favourably when the level of the water in the lower basin rises a little above the centre of the base of the enveloping case, without entirely submerging the latter. Occasionally the outer envelope is dispensed with, and the water is made to rise upon a close masonry channel; in which cases the loss of power entailed by moving the envelope is avoided. It is calculated that a workman can exercise, in a day of six hours' constant labour in turning an Archimedian screw, a useful effect equal to 637,283 lbs. raised 1 foot in height. [PROPELLER.]

ARCHITECTURE is sometimes defined to be 'the art of building.' We shall presently examine in what sense this definition ought to be explained, and how it ought to be limited.

The Greek term for architect is ἀρχιτέκτων (*architectōn*), which we find employed by Herodotus (iii. 60) in the same sense as the word *architect* now is: he informs us, that Rhœcus, a Samian, was the *architectōn* or architect of the great temple of Samos. We thus learn from positive testimony, that before the great buildings of Athens were erected, the term architect and the profession of an architect were distinctly recognised among the Greeks. But Herodotus also uses the word *architectōn* in the passage just referred to in another sense: he applies it to a person who made a tunnel by which the city of Samos was supplied with water; and this is an instance in which *building*, or *construction*, properly speaking, can hardly be said to have been employed. The great increase in works of this class in modern times has led to new designations, such as that of civil engineer, which we apply to those who construct artificial ports, roads, railways, tunnels, &c.; and though the engineer may often have occasion to *build*, and may also with propriety *decorate*, common usage has placed a determinate boundary between civil engineering and architecture.

In ascertaining the present meaning of terms, it is sometimes useful and often necessary to ascend to their primary signification, and to trace their historical progress. The Greek word *archi-tectōn* signifies the chief *fabricator* or *maker*; and the word *tectōn* itself (τέκτων) appears to mean, originally, a *worker in wood*, a *carpenter*, a *house-builder*, a *ship-builder*, &c. (See 'Iliad,' xv. 411; xxiii. 712; 'Od.' xvii. 384.) It is not, however, limited to those who were skilful in the working of wooden materials, but when coupled with a qualifying term (as in 'Il.' iv. 110; 'Hymn to Venus,' l. 12) it had a more extensive signification.

It is impossible to assign any exact meaning to the term architecture by any short definition. Architecture is not merely the 'art of building,' or of working materials of earth, timber, or stone, into the form of mounds, huts, caves, and walls. Thus we do not admit such mounds of earth as that raised to the memory of Alyattes, by Lake Gygæa, or of Silbury Hill near Marlborough, to possess an architectural character. Neither are the kraals of the Hottentot, nor the rude huts of other nations, entitled to this name, though such habitations undoubtedly have in each nation a particular and a tolerably uniform style of construction.

An excavation in a rock is not an architectural work, unless it possesses a certain symmetry and certain ornaments which characterise other similar works, so as to enable us to refer it to some class or kind of construction. Where such instances of excavations occur, the ornamental or architectural part is obviously only the copy of models in wood or stone previously erected on the earth. Such is the character of the rock temples of Elephanta, and the rock-cut tombs or temples in Nubia. The rude Pelasgic or Cyclopian walls of Tiryns in the Peloponnesus, and other similar structures in Italy, possess a distinctive character, which is seen in a more advanced and improved state in the military fortifications of Mycenæ, where we find also in what is known as the Treasury, or the Tomb of Atreus, a very remarkable subterraneous structure of nearly as early a date, and the oldest instance, as far as we know, now existing in Europe, of a construction in stone combined with the sister art of sculpture. We refer to the sculptured figures in high relief, commonly called lions, which stand over the great gateway. But even these can hardly be considered as architectural works.

The existing monuments in Great Britain which are supposed to be anterior to the Roman invasion of this island, are classed, whether correctly or not we shall not here inquire, under the general term of Druidical or Celtic. The most remarkable of these monuments, both for preservation and arrangement, is Stonehenge on Salisbury Plain in Wiltshire. Here we find stones, some of very large dimensions, placed upright in the ground, and forming a series of concentric circles. They are not merely rude masses, like those of Avebury near Silbury Hill, but they have evidently undergone some shaping and rubbing down so as to form tolerably regular parallelopipedons. We here observe also two stones placed upright, like posts or pillars, and another large stone placed over them like an architrave or lintel: the lintel is also secured by means of mortises and tenons: all this indicates certainly a regular principle of construction. But, with the exception of a few inquirers who are, perhaps, disposed to over-value Celtic remains, can any careful antiquarian trace the forms of our oldest churches and other ancient edifices, to the rude masses of the British monuments in this island? It is an historical fact, that the Romans introduced into England their own principles of building; and it is equally demonstrable that, with the exception, probably, of the arch, Roman architecture, as it is known to us, both from existing specimens and written books, is a modification and adaptation of Grecian architecture; it was probably introduced among the Romans by Greeks, and certainly generally practised by them even under the emperors. If we then trace the progress of architectural construction from the Greeks, through the Romans, to its introduction into western Europe, we may fairly assert that the term *architecture*, in its strictest historical sense, implies the adaptation of Grecian models to the buildings of our own times.

A building may be well arranged for all purposes of mere convenience, but if this is all it is not an architectural construction. To possess an architectural character it must combine internal convenience and fitness with beauty of external form, and with durability. If the external arrangement of a building should be compounded of those of several nations, such as Hindoo, Egyptian, and Greek, we should not admit this to be an architectural construction, even if the external form gave pleasure, which, however, is hardly a possible result; for it is essential to the character of an architectural structure, that the general arrangement and ornaments should have a unity of character and be referable to some one model.

Architecture arose, in fact, from the combination of sculpture with construction. *Building* may be older than sculpture, but sculpture combined with building produced architecture. From the Homeric poems we deduce only very vague ideas as to the structure of temples and palaces; we find no distinct indication of the arrangement of columns, which are the very essence of Greek architecture. But the arts of design, and even the arts of working in metal, had attained some excellence. (See in the 'Iliad,' book 18, the description of the shield of Achilles.) We find epithets derived from metal applied to the house of Alcinous and other buildings, from which we infer that they were structures of wood, and that the decorations were of metal; but we find no trace of columnar arrangement, or of an edifice of stone. ('Odyss.' vii. 84, &c.; iv. 45, &c.) Even in the time of Pausanias (x. 5, 11) there still existed at Lacedæmon the temple of Minerva, called the 'house of copper,' from which it would appear, that this and other ancient temples were mainly of wood, and ornamented with metal.

That the oldest material of sculpture was wood, is a fact in itself probable enough, and attested by the authority of Pausanias (viii. 17). Many of these wooden statues of high antiquity remained after the wooden temple itself had been exchanged for a more substantial edifice of stone. The ornamental parts of the stone structure, even in their simplest form, were no doubt derived from the art of the sculptor. The sculptor and the architect, in fact, were often united in the same person; and even when it became usual to separate these arts into two distinct branches, we can have no doubt that the skill of the architect, and the taste, at least, of the sculptor, were generally combined in the same individual. This was the case also with the mediæval architects, and not least with those of England, who frequently not only adapted the exterior forms of their edifices for the reception and display of sculpture, but had good taste enough to take care that these ornaments were in harmony with the whole design, and worthy of the edifice which was to receive them.

Further it is worthy of remark, though it seems to have escaped the observation of many writers, that the nation to which Europe is indebted for the elements of its architecture is also the nation to which we are indebted for our knowledge of geometry. That law of the mind which gave birth to the simple forms of the triangle, the circle, and the square, gave to man the elements of all his works of art. We are not aware of any nation that has had a system of architecture which has not also had a style of sculpture; nor do we know of any nation that has carried architecture to perfection, or even to a degree of excellence in its kind, that has not also had a system of geometry and arithmetic.

We have endeavoured briefly to show, what we believe to be strictly demonstrable, that the term architecture, *historically* explained, is the mode of constructing edifices which we have received from the Romans and the Greeks. But with the establishment of Christianity, and its diffusion over western Europe, a gradual modification was made in the forms of buildings devoted to religious worship: for it must be observed, that it is principally in the religious edifices of a nation that we find the essential principles of its architecture exhibited and preserved. This remark applies with equal truth to all nations that have left behind them examples of some definite style of building. The great ecclesiastical structures of western Europe now exhibit a character in appearance very different indeed from the models of Greek and Roman buildings. They gradually deviated from the heavy and rounded Norman arch, the type of which is undoubtedly the Roman arch, to the pointed and light constructions generally denominated the Gothic. That foreign ornaments of a barbarous or at least incongruous style were occasionally mingled with them by the numerous architects of the middle ages, cannot be denied; but still in the early ecclesiastical, and also in many of the civil structures of Italy, Germany, France, Flanders, and England, a distinct and new character of architecture may be seen; and this distinction became again so marked in the several countries of Europe, that the Gothic or pointed styles of England and various Continental countries have each a distinctive character, though they may all have had a common origin.

The architecture of a people is an important part of their history. It is the external and enduring form of their public life; an index of the state of knowledge and social progress. Architecture, therefore, to be understood aright, must be considered historically; must be considered, that is, in connection with the whole public and social life of the several nations in which it has been practised, and the particular times and circumstances in which it flourished. The architecture of the ancient Greeks, or that of the various European nations during the middle ages, would be very imperfectly understood if the architectural remains were studied apart from the external and inner history of the countries in which they are found. On the other hand, the existing edifices serve to illustrate and elucidate much that would, without their assistance, be but imperfectly comprehended.

No national architecture has ever been self-originated or invented. The architecture of every age and country where true architecture has existed, has grown out of some previous architecture. The architecture of Greece, the purest architecture which the world has ever seen, may be traced back to Assyria and Egypt. The architecture of Rome was derived immediately from Greece. The Oriental imagination transformed this into Byzantine; the Occidental into Romanesque; and borrowing something from both of these, the mind of the 13th century produced the Pointed or Gothic style, which the architects of Italy, Germany, France, and England, modified to suit the wants and characters of their respective countries.

But always it was a modification, adaptation, or development of a previous system, not a reproduction of it. No true architecture has ever been merely mimetic. Though the architecture of Greece derived its germ from Egypt and Assyria, it developed into its perfect beauty and suitableness only by the free influence of the Greek mind. So that of Rome owed whatever of beauty and fitness it possessed to its departure from, not to its conformity with the Greek type. So whatever there is of grandeur and glory in the wondrous Gothic of the middle ages, dates from its emancipation from the classic form. No imported architecture has ever been lasting. In our own country we have tried this, and the failure is palpable. Our architects have erected copies of the temples of Greece and Rome, alike for churches, museums, and town-halls: and, however much they may have been admired whilst the fashion lasted, and scholars imbued with classic ideas gave tone to public opinion, almost before they were finished, the fashion passed away, and they are now regarded with general dissatisfaction. To the Greek succeeded the Gothic, and though the passion for it be still fervid, the opinion is evidently fast gaining ground, that Gothic reproduction is as essentially vicious and untrue as that which it has supplanted.

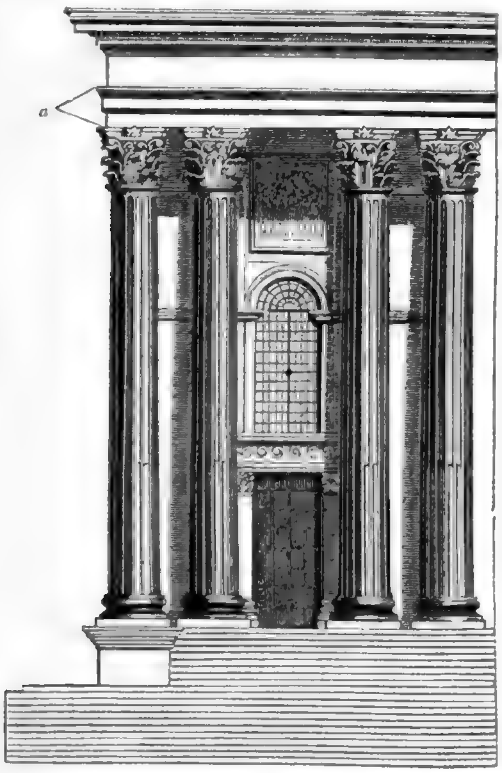
In fact, we may hope that we are in this country coming to understand that whilst an absolutely new style is a thing neither to be desired nor looked for, and that an eclectic style is an absurdity, the architecture of every age as well as every country, to be a true living architecture, must be a product of that age and country—adapted to its special wants, and circumstances, and character: developed out of some previously existing architecture, but adapted with perfect freedom to present purposes, and embodying to the fullest possible extent the scientific knowledge and artistic feeling of the present time.

And if this be so, the question of style will eventually, perhaps at no very distant day, settle itself. It will be felt that in every building there is a matter to be determined antecedent to all considerations of style. The first grand requisite is, as Vitruvius long ago pointed out, that a building shall be designed so as to answer as perfectly as possible the purpose for which it is erected: shall, in other words, possess the greatest attainable convenience and stability. When that is arrived at, the feeling for beauty and grandeur in the architect who has rightly studied his art, will suggest a style—an outward and visible clothing of the actual body—which shall be as evidently in conformity with it, and the most beautiful, because the most suitable, for it—be as properly adapted to the purpose it has to fulfil, and the locality in which it is placed—as the form and clothing and colour of an animal or a flower are recognised to be the most beautiful as well as the most suitable with which it could have been endowed.

Ornament then is an essential part of architecture. Without ornament there is no true architecture, only building. But it is a misconception of the true purpose of art to say that an edifice is erected for the sake of ornament. Architecture consists of construction and ornament. But ornament must not be a thing extraneous to the construction, a something added to it merely to please the eye. True ornament is the expression of the idea of a building. Equally with the building itself the ornament must possess unity, proportion, congruity; be a well considered whole, to which every part conduces, and of which every part *is* a part.

The history of the several great styles of architecture will be given and their distinctive characteristics be pointed out, under the names of the countries in which they flourished, or the terms by which they are best known, as EGYPTIAN, GRECIAN, ROMAN ARCHITECTURE, &c.; or BYZANTINE, GOTHIC, RENAISSANCE ARCHITECTURE, &c. The great architectural features will be found under their respective heads, as ARCH, ARCHITRAVE, COLUMN, &c. Some of the more important classes of buildings will also be separately described, as AMPHITHEATRE, Triumphal Arch [ARCH, TRIUMPHAL], CHURCH, TEMPLE, THEATRE. Constructive architecture will likewise be found fully treated of in a distinct series of articles. [ARCH; HOUSE; ROOF, &c.]

ARCHITRAVE, from a Greek word and a Latin one, meaning, when put together, *the principal beam*, is the lower part of any structure supported by pillars, or the lower beam which rests upon the columns



Part of the West front of St. Paul's Cathedral.

and joins them together, on which the whole entablature (or ornamental part which comes immediately above the columns) rests. It was also called by the Greeks and Romans *epistylion*, or *that which is on the columns*. Thus, when pillars support an arch, the voussoirs, or wedge-shaped stones which form the arch [ARCH], supply the place of an architrave, by which name they are sometimes called. In the same way the flat beam, or row of stones coming immediately above a door or window, is called the architrave. The architrave may have only one face or two, that is, may appear as one beam, resting on and joining the contiguous columns (as in the temple of Pæstum), or as two beams, the upper of which projects a little in front of the lower, as at *a* in the preceding cut. [COLUMN.]

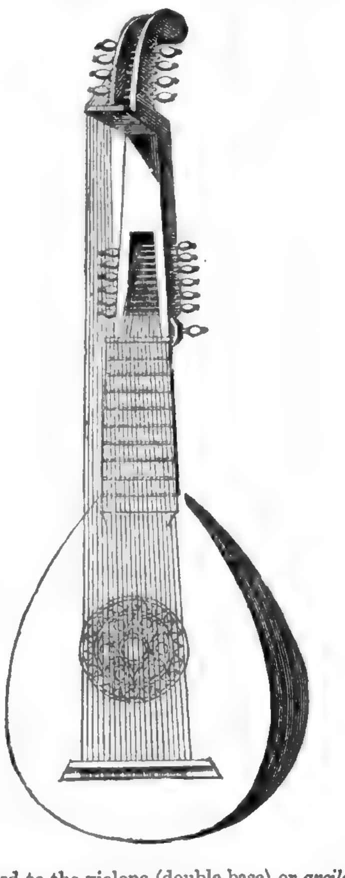
ARCHIVE, or ARCHIVES, a chamber or apartment where the public papers or records of a state or community are deposited: sometimes, by a common figure, applied to the papers themselves.

By some the word archive is supposed to have been derived from the Greek 'Αρχεῖα (*archeia*), a term used by Josephus in the sense of public registers, and considered to have been transmitted to us through the Latin of the middle ages. The Greek *archeion* seems, in its primary signification, to mean 'a council-house or state-house,' or 'a body of public functionaries,' as the Ephori at Sparta. (See Aristot. 'Polit.' book ii.; and Pausan. iii. 11.) Others derive it from *arca*, 'a chest;' such being, in early times, a usual depository for records. So Isidorus, 'Orig.' lib. xx. c. 9—"Archa dicta, quod arceat visum atque prohibeat. Hinc et archivum, hinc et arcanum, id est secretum, unde cæteri arcentur." "It is called Archa, because it does not allow (*arc*-eat) us to see what is in it. Hence also Archivum and Arcanum, that is, a thing kept secret, from which people are excluded (*arc*-entur)."

The Temple of Saturn, built in the time of the Republic, was the chief repository of the archives as well as of the public treasure of ancient Rome. In England the archives are kept in various and too often inconvenient places, but a Record Office has been partly completed in Fetter Lane, London, where some have been transferred. Some pains have also been taken to classify them, and make them more generally useful. Under the direction of the Record Commissioners, with the active assistance of Sir J. Romilly, the Master of the Rolls, several volumes of detailed catalogues of these papers have been published, and more are in preparation. The building was intended for the reception of all the archives, but the portion at present erected will contain only a very small part, and the work has for a considerable time been discontinued. The national archives of France are preserved in the Hôtel Soubise at Paris; those of the Courts of Justice, in La Sainte Chapelle at the Palais de Justice.

ARCHIVOLT, or ARCHIVAULT, means, literally, the *principal turning*, or *arch*, and is applied to any ornamented band or moulding which runs round the lower part of all the voussoirs of an arch. When this part of the arch is plain, with square edges, as in arches of the Romanesque style, it is called a *soffit*.

ARCH-LUTE, a large lute, or double-stringed theorbo (THEORBO), formerly used by the Italians for the base parts, and for accompanying the voice. In the early editions of Corelli's 'Sonatas,' the principal



base staff is assigned to the violone (double-base) or *arcileuto*. According to Kircher ('Musurgia,' lib. vi.), this instrument had fourteen notes, the highest whereof was A, the fifth line in the base, the lowest the double G below; and possessed considerable power. It was about five feet in extreme length, and proportionally large in the body. At the commencement of the last century this instrument (invented, as is supposed, in the 16th century) was much in use; Handel employed it in many of his early operas. The office of Lutenist still continues as part of the establishment of the Chapel-royal, though the place has been a sinecure for nearly a century.

A'RCHON, a Greek word written in Roman characters, signified originally one who had rule or command, either civil or military. In modern usage it is known only as the title of certain magistrates of the Athenians, of whom we propose to give some account in this article.

On the abolition of regal government at Athens, on the death of Codrus, the chief power was still intrusted to a single magistrate, or archon, without the title of king (βασιλεύς), which was more directly associated with the idea of arbitrary rule. The new office was hereditary; at least it is said to have been enjoyed successively by lineal descendants of Medon, the first archon, who was himself a son of

Codrus, the last king. The Athenians were fond of attributing to Theseus the origin of their democracy; by which probably they meant that many of his regulations had a popular tendency, and that his general reformation of the state, which was favourable to that part of the population which had possessed no political rights, was accompanied by a permanent relaxation of regal authority. (Plut., 'Vit. Thes.' c. 25.) The prerogative of the archon was still further limited; for he was made responsible to his fellow citizens for the acts of his government. (Paus. iv. 5, 10.) Tradition told of thirteen hereditary archons, after whom, about B.C. 752, the chief magistrate was appointed to his office for ten years, but was still at first taken from the Medontidæ, or descendants of Medon. We have the name of Charops and of six others after him as decennial archons; but in B.C. 714 the archonship was thrown open to all the order of nobles, and the last three of the decennial archons were not of the family of Medon. (Vell. Paterc. 1, 8.) Another revolution, which is placed by Mr. Grote B.C. 683, limited the duration of the office to a single year, at the same time dividing the charge of administration between the chief magistrate and eight others, thus forming a council of state, which consisted of nine magistrates or archons. Hence they are sometimes mentioned by the Greek writers under the general designation of The Nine. These officers had their distinguishing titles and duties, of which we shall presently speak, when we have carried a little farther the general history of this new constitution. We have seen that the first archon was, like his royal predecessor, the head of the government. The decennial archons had doubtless the same place and character, and the annual magistrates for a time exercised collectively the political power before vested in a single ruler. Their names and number, and in great measure the particular civil duties assigned to them, remained unaltered whilst Athens continued to possess an independent government; but the course of events wrought a most important change as to their position in the state. This change, to which in earlier times there was a gradual approximation, was effected mainly by the increased activity of the ecclesia, or popular assembly, which received its first impulse from the regulations of Solon, about B.C. 594, was urged on more effectually by the reformation of Cleisthenes (B.C. 509), and was confirmed by the consequences of the Persian war, by which the *thetes*, or lowest class of citizens, which supplied the naval strength of Athens, were taught to know their power. (Aristot., 'Polit.' 2, 9, 4.) From the time that the ecclesia interfered habitually and directly with the government of the republic, the actual minister of state was the person who enjoyed the confidence of the people, which neither the office of archon nor any other office could procure. The inevitable consequence was, that the archons sunk from ministers of state into municipal officers of high rank. We have thought it worth while to point attention to this fact, from having had occasion to observe that young students of Athenian history are sometimes perplexed by the apparent inconsistency of the accounts given them of the first appointment of archons with the little notice bestowed upon these magistrates in the general history of the republic. They read of important public measures, and of the persons who originated and executed them, whilst the name of archon seldom occurs in Grecian history, except as marking the year in which certain events took place. (See Thucyd. ii. 2.) Pericles, without the office of archon, to which it was not his chance ever to attain, enjoyed a degree of power which was not possessed during the freedom of the republic by any other citizen. Perhaps no one who read with the least attention would find the difficulty, if he were not in some measure led to it by popular works on Grecian antiquities, which too commonly present an accumulation of facts and authorities without sufficiently discriminating the times to which the different statements refer.

The annual archons, from their first appointment down to the time of Solon, were taken from the eupatridæ, or nobles, to which class all political power seems to have been confined. This is rather assumed from what we know of the progress of civil and political society at Athens, than asserted on any authority of much weight. The establishment by Solon of a timocracy, or government in which political power was distributed with reference to property, put an end to the claims of noble blood; but since the archons were by this regulation taken from the wealthiest class of citizens (οἱ πεντακοσιομέδιμνοι), the noblest families probably still continued chiefly to supply the archons for each year, till the celebrated law of Aristeides, enacted about B.C. 479, threw open the offices of state to the whole body of the people. (Plut., 'Vit. Arist.' c. 1, and c. 22.) From this time no qualification was requisite in an Athenian citizen for the office of archon but fair fame and freedom from bodily defect.

The mode of appointment presents some difficulties, from the want of precise information. It appears that the archons were originally elected by suffrage, and the elective franchise was probably confined to the noble class from which they were taken. By Solon, eligibility to the office, and perhaps the right of suffrage, were enlarged, but the mode of appointment remained the same. In after times, and even as early as the first Persian invasion of Greece, the appointment was by lot. The case of Aristeides seems to have been an exception to the general rule, and may be attributed perhaps to his high character and eminent services. (Aristot. 'Polit.' 2, 9, 2; Herod. 6, 109; Plut. 'Vit. Arist.' c. i., p. 481, ed. Reisk, compared with p. 479.) We have no information which enables us to fix the time when the change was effected. It has been attributed, with some probability, to Cleisthenes, but we know only with certainty that they were at one time elected and at some subsequent period appointed by lot. It must not be supposed that all the citizens were eager to avail themselves of the double opportunity offered by the new mode of appointment and the law of Aristeides. It seems that the poorest of them declined the hazard of the lot, which might throw upon them a burdensome honour. (Xen. 'Rep. Athen.' 1, 3.)

Of the nine archons, one, usually termed *the* archon, was chief, and had the title of *epónymus* (ἐπώνυμος), or name-giver, because the year in which he served the office was called by his name, as among the Romans the year was distinguished by the names of their consuls. Thus his name appears at the head of all public decrees (see Dem. 'De Cor.;' Thucyd. 5, 19), and generally in all solemn records of state. The list, from the time of Creon, the first annual archon, is nearly complete and trustworthy. Of the remaining eight, one was called the king (βασιλεύς), another the *polemarch*, and the last six had the general title of *thesmothetæ*. Before admission to their office, they were subjected, like other public officers, to the examination called *dokimasia* (that is, trial or examination), for the purpose of ascertaining that they were Athenians of pure blood, whole of limb, and without blemish in their characters. With reference to the last point, they were asked if they had treated their parents kindly. When once invested with their office and adorned with the chaplet, the distinguishing mark of it (Æsch. 'contra. Tim.' p. 3, 33), they were especially protected by the laws from all insult and outrage, and were exempted even from those public burdens which were not included in the general exemption granted to their most favoured citizens, the descendants of Harmodius and Aristogeiton. (Dem. 'contra. Lept.' p. 462, 20; and p. 465, 17.) There is reason to believe that they were members of the council of Areopagus by virtue of their office. [AREOPAGUS.] It is certain that they passed from their annual magistracy to a permanent seat in that council.

Their public duties had reference for the most part to the administration of justice. In some courts, and in certain causes, they were the presiding judges. On some occasions they had the execution only of the sentence pronounced by other judges; but it seems to have formed a large if not the most considerable part of their legal duties to bring causes into court (εἰσάγειν, Dem. 'contra Lacr.' p. 940, 5–20) to be tried before the proper tribunal, not in the character of public prosecutors, but on application from the plaintiff or accuser, in which case their province was somewhat similar to that of an English grand jury in finding and ignoring bills. Sometimes, perhaps, the application to the archon was a form of little more importance as to the responsibility of the archon than that in English law of suing out a writ. To each of the first three archons, and collectively to the six thesmothetæ, a distinct province and peculiar duties were assigned. Incidental notices of these are to be found scattered over the Greek classics, especially in the Attic orators; more systematic accounts occur in the earlier lexicographers and antiquarians, among whom Julius Pollux may be particularly distinguished, whose authority would have more weight if we were better acquainted with the sources from which their information was derived and the times to which their accounts refer. Copious collections have been made from them by modern compilers, of whom, perhaps, the most popular in our language is that of Archbishop Potter. We shall present our readers with only a brief outline, sufficient to convey a general view of the separate jurisdiction of these magistrates in the later times of the Athenian republic.

It seems to have been the duty of the chief archon, or epónymus, to throw his official protection around those whose interests were most liable to be overlooked in the ordinary execution of the law. Hence he was the appointed guardian of orphans and minors. He was also charged with a more general superintendence in matters which concerned the safety and good order of the state than was committed to his colleagues.

The king archon was more especially concerned with religious matters. He was required to preside at the performance of the most solemn sacrifices. He had a certain control over the ministers of religion, and either himself tried offenders, or originated trials, in cases of impiety. It is hardly necessary to observe, that in the early periods of regal government kings were almost universally the chief ministers of religion. It is commonly supposed that the title of this archon was intended to denote the transfer of an important part of the king's prerogative to the magistrate who, in the department of religion, supplied his place.

The office of the polemarch was doubtless in its first institution that which the name implies, to command in war; and even as late as the battle of Marathon, we find the polemarch Callimachus acting an important part in the council of war which preceded it, and commanding in virtue of his office the right wing of the Athenians in the engagement; but in later times, when the generals of the republic were immediately chosen by the people, the polemarch was confined to the discharge of civil duties, and particularly had cognisance of matters which concerned the strangers and *metics* (resident aliens) at Athens, exercising a jurisdiction in this respect not unlike that of the prætor peregrinus at Rome.

The thesmothetæ should, according to the meaning of their title, have been legislators, or propounders of laws. It was not however their office to introduce laws, but rather to watch over the conduct of those who put themselves forward as legislators, and also annually to examine the existing laws for the purpose of removing contradictory and superfluous enactments—to keep, as it were, the statute-book in a pure and consistent state. (Dem. 'contra Lacr.' p. 940, 10, and 12; 'contra Zenoth.' p. 890, 10; Lys. 'contra Andoc.' p. 104, 15; Herod. 6, 109, 111; Lys. 'contra Panc.' p. 166, 32, and 40.) It appears that the whole college of archons was sometimes assembled in council (Dem. 'contra Meid.' p. 542, 2); but we have no information respecting the authority which they collectively exercised.

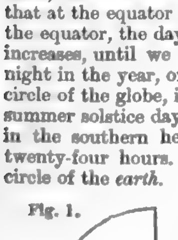
For further information on the various and important duties assigned to the different archons, in addition to this brief and general notice, the reader is referred to the authorities mentioned above; but we would remind the young student, in his inquiries, that the reliance to be placed on the accuracy of even a credible and well-informed author must depend in some measure on the circumstances under which his information is given; and this should especially be kept in mind when, as in the subject of the present article, all our information, so far as it is supplied by the Greek classics, is obtained, not from regular essays, but from incidental notices. Our meaning in this caution will be best explained by an instance. The subject of inquiry may be the manner in which certain officers were appointed; and this, as in the case of the archons, may have varied at different times. The mode of appointment may, according to a common practice with the Athenians, be implied by an epithet familiarly joined with the title of the office. Now, it is possible that an author, who when writing professedly on the subject would have given minutely accurate information, may use this epithet, familiar to him, inaccurately with reference to the times of which he is speaking, if the circumstance indicated by it is of no importance to the subject immediately before him. Evidence drawn from a casual expression must often be taken into account, but then it should be carefully rated at its proper value.

ARCOGRAPH. [CYCLOGRAPH.]

ARCTIC CIRCLE. The term *arctic* is derived from the Greek, and signifies literally *of* or *belonging to the bear*, meaning the constellation of that name. *Arctic circle* had formerly a different signification from that which it now has. Among the Greeks it meant the parallel to the equator which just touches the horizon, being entirely above it, and which therefore separates those parallels which are always above, from those which are partly above and partly below, the horizon. (See Strabo, Casaub. p. 95.) Similarly the antarctic circle (if the phrase were used) would be a parallel to the equator which touches the horizon, being entirely below it, and which therefore separates those parallels which never rise above, from those which are partly below and partly above, the horizon. Thus every different latitude had a different arctic circle; and in the latitude in which astronomy was first cultivated, the great bear just swept the sea, and did not set, whence the boundary circle obtained its name.

In the modern sense of the term, it is one fixed circle, or very nearly so; and the first use of it as such is found in the celebrated treatise on the sphere, by Holywood, better known by the name of Sacrobosco, published in the twelfth century. For the complete meaning of the term, we refer to DAY. We can only here briefly remind the reader that at the equator all days are equal; that in going northwards from the equator, the day of the summer solstice lengthens as the latitude increases, until we reach the pole, where there is but one day and night in the year, of six months each. There must therefore be some circle of the globe, in the northern hemisphere, at which the longest or summer solstice day is just twenty-four hours; and an opposite circle in the southern hemisphere, at which the sun does not appear for twenty-four hours. The first is the *arctic*, the second the *antarctic*, circle of the *earth*. We need hardly say, that at the day of the *winter* solstice in the northern hemisphere, there is a day of twenty-four hours in length at the *antarctic* circle.

Fig. 1.



P and p (*fig.* 2.) are the north and south poles of the earth, the lines through which serve to remind us of the earth's axis. A B is the equator, and O H and O L are the directions in which the sun is seen at the northern summer and winter solstices, that is, the line which points to the sun rises and falls between H O and O L twice in a year. We do not consider the *apparent* motion of the sun *round* the earth, because, as the sun is always on the meridian of some place, and any conclusion respecting day and night drawn from one meridian holds good for any other, we may conceive the meridian P B p A to move round with the sun. Or, to consider it in another point of view, instead of supposing the sun to appear to move round, let it remain in the fixed meridian, P B p A, and increase the daily rotation of the earth by a quantity equal to the daily motion of the sun on the equator, which will preserve the *relative* rotations, leaving us only to take notice of the rise and fall of the sun in the ecliptic; which is the cause of the peculiar phenomena of the arctic circle. The semicircle O V, in the first figure, is supposed to be cut out and applied to the right hand figure, O to O, in such manner that the needle, V, shall always be directly opposite to the sun. In the figure (2.) are given the extreme positions of O V; namely, M U m, at the northern summer, N W n, at the northern winter, solstice. The semicircle O V covers all those parts of the earth which do not see the sun, and the rotation round the axis, P p, brings every part of the earth under O V when its night begins. M N and $m\,n$ are the arctic and antarctic circles. By cutting out a semicircle equal to O V, and placing it

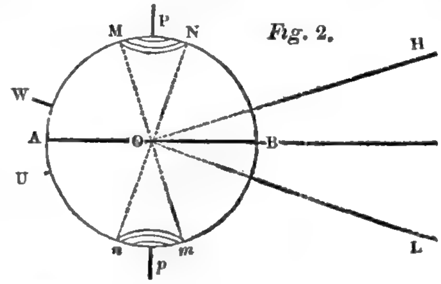


Fig. 2.

in different positions on the second figure, the following will appear, on a little consideration:

1. At the summer solstice (when V is at U) all circles above M N will be in light for twenty-four hours, and all below $m\,n$ in darkness: and *vice versâ* at the winter solstice.

2. At the equinoxes (V is at A) every circle will be in light for twelve hours, and the same time in darkness.

3. During the passage from the equinox to the summer solstice (V moves from A to U), at every moment some circle above M N emerges entirely into light, and an opposite circle below $m\,n$ begins to be entirely covered by darkness: and both states remain until the return of the circle O V in the next quarter of the year. And *vice versâ* for the passage from the equinox to the winter solstice (when V moves from A to W).

4. No circle lying between M N and $m\,n$ is ever entirely in light or entirely in darkness.

Hence, to find the duration of light at any place above the arctic circle, that is, to find during what part of the year the sun performs his daily rotation entirely above the horizon, look in an almanac for the times before and after the summer solstice, at which the *declination* of the sun is equal to the *polar distance* (or latitude subtracted from 90°) of the place. Between those two times there is perpetual light. For example, the north point of Nova Zembla (latitude 75°, polar distance 15°) will have perpetual light between May 1 and August 12, 1859. For the time of perpetual darkness do the same with the winter solstice: thus there will be perpetual darkness at the above-mentioned place from November 3, 1859, to February 9, 1860.

The north polar distance of the arctic circle is equal to the angle H O B, the greatest declination of the sun, or the OBLIQUITY of the ecliptic. The south polar distance of the antarctic circle is the same. This quantity changes very slightly from year to year. It is as follows:

January 1, 1858, 23° 27′ 28″·29
January 1, 1859, 23° 27′ 27″·84

decreasing at present by about half a second yearly.

The arctic and antarctic circles are the boundaries which separate the frigid from the temperate zones, as they are called. The part of the earth included within each of the two is about $4\frac{1}{10}$ per cent. of the whole surface of the globe. The best known points through or near which the arctic circle passes are Cape North in Iceland, the Maelstrom whirlpool, the mouth of the Oby, Behring's Straits, and the south of Melville Island. For discoveries of land within the antarctic circle, see ANTARCTIC OCEAN, in GEOG. DIV. of ENG. CYC.

The arctic and antarctic circles of the heavens occupy positions with respect to the celestial poles similar to those occupied by the same circles on the earth. Thus a traveller going round the arctic circle would always have some point of the celestial arctic circle directly over head, or in his zenith. But the term is hardly ever employed by astronomers.

In all that precedes we have taken no notice of REFRACTION, the effect of which is to raise the sun a little towards the nearest pole at every point of the globe, thus lengthening the day and diminishing the night. In some latitudes the effect would be very considerable, and would increase the duration of light by as much as a day.

ARCTURIN. [ARBUTIN.]

ARCTU'RUS, or α Boötis, a star of the first magnitude in the constellation Boötes. It derives its name from two Greek words, signifying the tail of the bear, and, though not in the latter constellation, it is very nearly in a right line drawn through the two hinder stars of the tail (ζ and η). It rises N.E. by E. at Greenwich, and is on the meridian in about $7\frac{3}{4}$ hours after rising; which takes place at half-past seven A.M. on the 1st of January, and about two hours later for the first of every succeeding month. Its mean places are as follows:

	Right Ascension.	Declination.
Jan. 1, 1859 . .	14^h 9^m $13^s{\cdot}8$	19° 55′ 5″·5
Jan. 1, 1860 . .	14 9 16·6	19 54 46·6

Its annual increase of right ascension is $2^s{\cdot}8$; its annual decrease of declination is 18″·9. This is not all owing to precession and nutation, as the star has a proper motion (or change of place relatively to surrounding stars), the value of which is thus given in the catalogue of stars published by the British Association in 1845.

Mean Annual Decrease in R. A.	Decl.
1''·17	1''·96

Formerly the conclusion was sometimes drawn that Arcturus was the nearest star to our system, from its being a brilliant star with so decided a proper motion. This, which was but a faint presumption at the time, is now overturned by the known fact that there are much smaller stars (μ Cassiopœiæ, for example) which have much larger proper motions.

ARE, the modern French measure of surface, forming part of the new decimal system adopted in that country after the revolution. It is obtained as follows:—the metre, or measure of length, being the forty-millionth part of the whole meridian, as determined by the survey, is 3·2809167 English feet; and the *are* is a square, the side of which is 10 metres long. The following denominations are also used:—

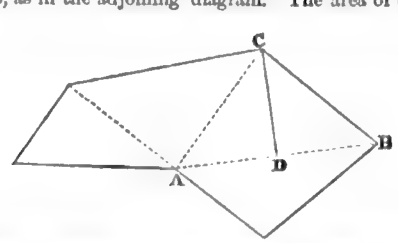
Decare	is 10 ares.
Hectare	„ 100 „
Chilare	„ 1000 „
Myriare	„ 10,000 „
Deciare	„ $\frac{1}{10}$ of an are.
Centiare	„ $\frac{1}{100}$ „
Milliare	„ $\frac{1}{1000}$ „
The are is	100 square metres.
or	947·68175 French sq. feet.
or	1076·44144 English sq. feet.

The hectare is generally used in describing a quantity of land. It is 2·4711695 English acres, or $404\frac{2}{3}$ hectares make 1000 acres, which disagrees with the first result by less than 1 part out of 50,000.

A'REA. This term is a Latin word, and means the same thing as *superficies*, or *quantity of surface*, but is applied exclusively to plane figures. Thus we say, "the *surface* of a sphere, the *area* of a triangle," and "the *surface* of a cube is six times the *area* of one of its faces." The word is also applied to signify any large open space, or the ground upon which a building is erected; whence, in modern built houses, the portion of the site which is not built upon is commonly called the *area*.

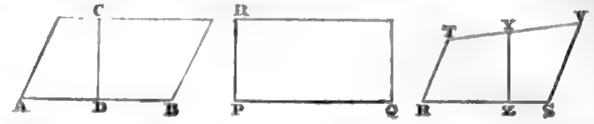
Returning to the mathematical meaning of the term, the measuring unit of every area is the square described upon the measuring unit of length: thus, we talk of the square inches, square feet, square yards, or square miles, which an area contains. And two figures which are *similar*, as it is called in geometry,—that is, which are perfect copies one of the other on different scales, have their areas proportional to the *squares* of their linear dimensions. That is, suppose a plan of the front of a house to be drawn so that a length of 500 feet would be represented in the picture by one of 3 feet. Then the area in the real front is to the area of the front in the picture in the proportion of 500 times 500 to 3 times 3, or of 250,000 to 9. Similarly, if the real height were 20 times as great as the height in the picture, or in the proportion of 20 to 1, the real area would be to that of the picture as 20 times 20 to once one, or as 400 to 1; that is, the first would be 400 times as great as the second.

Any figure which is entirely bounded by straight lines may be divided into triangles, as in the adjoining diagram. The area of every triangle



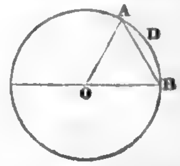
may be measured separately by either of the following rules, in which the word in italics may mean inches, yards, miles, or any other unit, provided only that it stands for the same throughout. 1. Measure a side, A B, of the triangle A B C, and the perpendicular C D which is let fall upon it from the opposite vertex, both in *units*. Half the product of A B and C D is the number of square *units* in the triangle A B C. Thus, if A B be 30 yards, and C D 16 yards, the triangle contains 240 *square* yards. 2. Measure the three sides, A C, C B, B A, in *units*; take the half sum of the three, from it subtract each of the sides, multiply the four results together, and extract the square root of the product; this gives the number of square *units* in the triangle. For instance, let the three sides be 5, 6, and 7 inches; the half sum is 9, which, diminished by the three sides respectively, gives 4, 3, and 2. 9, 4, 3, 2, multiplied together, give 216, the square root of which is 14·7, $14\frac{7}{10}$ very nearly. The triangle therefore contains about $14\frac{7}{10}$ *square* inches.

The following rules may be applied in the following cases:—for a parallelogram, multiply A B, a side, by C D, its perpendicular distance from the opposite side; for a rectangle, multiply together adjoining sides, P Q and P R; for a four-sided figure, in which R T and S V are



parallel, but T V and R S converge, multiply R S, one of the converging sides, by Y Z, its perpendicular distance from the middle point of the other. When R T and S V are perpendicular to R S, then Y Z is half the sum of R T and S V.

To find the area of a circle, multiply the radius O A by itself and the result by 355; then divide by 113. To find the area of the sector O A D B, see ANGLE. To find the area of the portion A B D, find those of the sector O A D B, and the triangle O A B separately, and subtract the second from the first. In all these cases, the result is in the *square* units corresponding to the *linear* units in which the measurements were made.

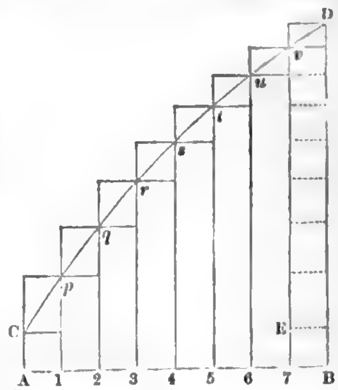


The area of a curvilinear figure can only be strictly found by mathematical processes too difficult to be here described, but the following method will give an idea of the principles employed. Let A C D B be a curvilinear figure bounded by the curve C D and the lines C A, A B, B D, of which the first and third are perpendicular to the second. Divide A B into any number of equal parts (eight is here supposed) by the points 1, 2, 3, &c., and construct the accompanying obvious figure by making A p, 1 q, &c., parallelograms. It is plain that the area sought, A C D B, is greater than the sum of the inscribed rectangles, denoted by the letters or numbers at opposite corners,

1 C, 2 p, 3 q, 4 r, 5 s, 6 t, 7 u, B v;

and that it is less than the sum of the circumscribing rectangles

A p, 1 q, 2 r, 3 s, 4 t, 5 u, 6 v, 7 D.



Therefore the area sought does not differ from either of these sums by so much as they differ from one another; but the sums differ from one another by the sum of the rectangles

C p, p q, q r, r s, s t, t u, u v, v D,

which, placed under one another, give the rectangle D E, which is less than D 7: consequently neither sum differs from the area sought by so much as D 7. But by carrying the division of A B, with which we set out, to a sufficient degree, the area of D 7 might have been reduced to any extent which might have been thought necessary; that is, name any fraction of a square inch, however small, and A B can be divided into such a number of equal parts that D 7 shall be smaller than that fraction of a square inch. Hence the sum of the inscribed or circumscribed parallelograms may, by dividing the line A B sufficiently, be made as nearly equal to the area as any practical purpose can require.

The accuracy of the preceding process will be increased by summing, not the parallelograms, but the figures

A C p 1, 1 p q 2, 2 q r 3, &c.,

considering C p, p q, q r, &c., as straight lines. This will be equivalent to adding half the rectangle D E to the sum of the rectangles aforesaid. The practical rule is—Add all the intermediate ordinates, 1 p, 2 q, &c., to the half sum of the extreme ordinates A C and B D: multiply the total by the common value of A 1, or 1 2, &c. This approximation is the first step of the method of QUADRATURES, which see.

The mathematical process of finding the area carries the preceding approximation one step further, and finds what is the limit to which the sum of the inscribed parallelograms approaches nearer and nearer, as the number of divisions of A B is increased. This limit, it is easy to show, is an exact expression for the area required. If x represent one of the lines A 1, A 2, &c., and y the corresponding line 1 p, 2 q, &c., the area of the curve is found by the process of the integral calculus thus represented:

$$\int y\, d\, x,$$

or, in the language of fluxions,

fluent of $y\,\dot{x}$.

A process similar to the preceding is employed by surveyors in measuring a field whose boundaries are curvilinear. [SURVEYING; OFFSET.]

The investigation of the area of a curve was formerly called the *quadrature* of the curve (*quadratum*, a square), because, before the application of arithmetic to geometry, the most convenient method of representing an area was by giving the square to which it is equal.

For some practical purposes the following experimental method of finding the above area might suffice. Cut out the figure A B C D in pasteboard (heavy wood or metal would be better); out of the same pasteboard cut a square inch or other unit; and weigh both the pieces thus cut out accurately. Then the weight of the first piece divided by that of the second will give the number of square units in the area required, if the pasteboard or other material be of moderately uniform thickness. A method similar to that of Archimedes (see his Life, in BIOG. DIV.) might easily be devised.

AREOPAGUS, COUNCIL OF, a celebrated council, so called from the hill of that name, on which its sessions were held. It was also called the council above (ἡ ἄνω βουλή), to distinguish it from the council of five hundred, whose place of meeting was in a lower part of the city, known by the name of the Ceramicus (Paus. 1, 3, 4). Its high antiquity may be inferred from the well-known legends respecting the causes brought before it in the mythical age of Greece, among which that of Orestes, who was tried for the murder of his mother, has obtained especial celebrity (Æschyl. 'Eumen.'); but its authentic history commences with the age of Solon. There is, indeed, as early as the first Messenian war, something like historical notice of its great fame, in the shape of a tradition preserved by Pausanias (iv. 51), that the Messenians were willing to commit the decision of a dispute between them and the Lacedæmonians, involving a case of murder, to this council of Areopagus. We are told that it was not mentioned by name in the laws of Draco, though its existence in his time, as a court of justice, can be distinctly proved (Plut. 'Vit. Sol.' c. 19). It seems that the name of the Areopagites was lost in that of the Ephetæ, who were then the appointed judges of all cases of homicide, as well in the court of Areopagus, as in the other criminal courts. (See Müller, 'History of the Dorians,' vol. i. p. 352, English translation.) Solon, however, so completely reformed its constitution, that he received from many, or, as Plutarch says, from most authors, the title of its founder. It is, therefore, of the council of Areopagus, as constituted by Solon, that we shall first speak; and the subject possesses some interest from the light which it throws on the views and character of Solon as a legislator. It was composed of the archons of the year [ARCHON], and of those who had borne the office of archon. The latter became members for life; but before their admission, they were subjected, at the expiration of their annual magistracy, to a rigid scrutiny (*dokimasia*) into their conduct in office, and their morals in private life. Proof of criminal or unbecoming conduct was sufficient to exclude them in the first instance, and to expel them after admission. Various accounts are given of the number to which the Areopagites were limited. If there was any fixed number, it is plain that admission to the council was not a necessary consequence of honourable discharge from the dokimasia. But it is more probable that the accounts which limit the number are applicable only to an earlier period of its existence. (See the anonymous argument to the oration of Demosthenes against Androtion.) It may be proper to observe, that modern histories of this council do not commonly give the actual archons a seat in it. They are, however, placed there by Lysias the orator ('Areop.' p. 110, 16-20), and there is no reason to think that in this respect any change had been made in its constitution after the time of Solon. To the council thus constituted Solon entrusted a mixed jurisdiction and authority of great extent, judicial, political, and censorial. As a court of justice, it had direct cognizance of the more serious crimes, such as murder and arson. It exercised a certain control over the ordinary courts, and was the guardian generally of the laws and religion. It interfered, at least on some occasions, with the immediate administration of the government, and at all times inspected the conduct of the public functionaries. But, in the exercise of its duties as public censor for the preservation of order and decency it was armed with inquisitorial powers to an almost unlimited extent.

It should be observed, that in the time of Solon, and by his regulations, the archons were chosen from the highest of the four classes into which he had divided the citizens. Of the archons so chosen, the council of Areopagus was formed. Here, then, was a permanent body, which possessed a great and general control over the state, composed necessarily of men of the highest rank, and doubtless in considerable proportion of eupatridæ, or nobles by blood. The strength of the democracy lay in the *ecclesia* or popular assembly, and in the ordinary courts of justice, of which the *dikasts*, or jurors, were taken indiscriminately from the general body of the citizens; and the council of Areopagus exercised authority directly or indirectly over both. The tendency of this institution to be a check on the popular part of that mixed government given by Solon to the Athenians, is noticed by Aristotle ('Polit.' ii. 9, and v. 3, ed. Schneid). He speaks, indeed, of the council as being one of those institutions which Solon found and suffered to remain; but he can hardly mean to deny what all authority proves, that in the shape in which it existed from the time of the legislator, it was his institution.

The council, from its restoration by Solon to the time of Pericles, seems to have remained untouched by any direct interference with its constitution. But during that interval two important changes were introduced in the general constitution of the state, which must have had some influence on the composition of the council, though we may not be able to trace their effects. The election of the chief magistrates by suffrage was exchanged for appointment by lot, and the highest offices of state were thrown open to the whole body of the people. [ARCHON.] But about the year B.C. 459, Pericles attacked the council itself, which never recovered from the blow which he inflicted upon it. All ancient authors agree in saying that a man called Ephialtes was his instrument in proposing the law by which his purpose was effected, but unfortunately we have no detailed account of his proceedings. Aristotle and Diodorus state generally that he abridged the authority of the council, and broke its power (Arist. 'Polit.' ii. 9; Diodor. Sic. xi. 77). Plutarch, who has told us more than others ('Vit. Cim.' c. 15; 'Vit. Pericl.' c. 7), says only that he removed from its cognisance the greater part of those causes which had previously come before it in its judicial character, and that, by transferring the control over the ordinary courts of law immediately to the people, he subjected the state to an unmixed democracy. Little more than this can now be told, save from conjecture, in which modern compilers have rather liberally indulged. Among the causes withdrawn from its cognisance, those of murder (φονικαὶ δίκαι) were not included; for Demosthenes has assured us ('Contr. Aristocr.' p. 641-2), that none of the many revolutions which had occurred before his day had ventured to touch this part of its criminal jurisdiction. There is no reason to believe that it ever possessed, in matters of religion, such extensive authority as some have attributed to it, and there is at least no evidence that it lost at this time any portion of that which it had previously exercised. Lysias observes ('Areop.' p. 110, 46), that it was in his time charged especially with the preservation of the sacred olive-trees; and we are told elsewhere that it was the scourge of impiety. It possessed, also, long after the time of Pericles, in some measure at least, the powers of the censorship. (Athenæus, 4, 64, ed. Dindorf.)

Pericles was struggling for power by the favour of the people, and it was his policy to relieve the democracy from the pressure of an adverse influence. He assigned salaries to the numerous dikasteries, which sat in the market-place, and thus popularised the jurisprudence. By increasing the business of the popular courts, he at once conciliated his friends, and strengthened their hands. The council possessed originally some authority in matters of finance, and the appropriation of the revenue. In later times, the popular assembly reserved the full control of the revenue exclusively to itself, and the administration of it was committed to the popular council, the senate of five hundred. It seems that, at first, the Areopagites were invested with an irresponsible authority. Afterwards they were obliged, with all other public functionaries, to render an account of their administration to the people. (Æsch. 'Contr. Ctes.' p. 56, 30.) Both these changes may, with some probability, be attributed to Pericles. After all, the council was allowed to retain a large portion of its former dignity and very extensive powers. The change operated by Pericles seems to have consisted principally in this: that, from having exercised independent and paramount authority, it was made subordinate to the ecclesia. The power which it continued to possess was delegated by the people, but it was bestowed in ample measure. Whatever may have been the effect of this change on the fortunes of the republic, it is probable that too much importance has been commonly attached to the agency of Pericles. He seems only to have accelerated what the irresistible course of things must soon have accomplished. It may be true that the unsteady course of the popular assembly required some check, which the democracy in its unmitigated form could not supply, but the existence of an independent body in the state, such as the council of Areopagus as constituted by Solon, seems hardly to be consistent with the secure enjoyment of popular rights and public liberty; which the Athenian people, by their naval services in the Persian war, and the consequences of their success, had earned the right to possess, and the power to obtain. It ought not, however, to be concluded, that institutions unsuitable to an altered state of things were unskilfully framed by Solon, or that he surrounded the infancy of a free constitution with more restrictions than were necessary for its security. He may still deserve the reputation which he has gained of having laid the foundation of popular government at Athens.

With respect to the censorship, we can show, by a few instances of the mode in which it acted, that it could have been effectually operative only in a state of society from which the Athenians were fast emerging before the time of Pericles. The Areopagites paid domiciliary visits, for the purpose of checking extravagant housekeeping (Athenæus, 6, 46). They called on any citizen at their discretion to account for the employment of his time (Plut. 'Vit. Sol.' c. 23). They summoned before their awful tribunal a little boy for the offence of poking out the eyes of a quail (Quinctil. 5, 9, 13). They fixed a mark of disgrace on a man who had dined in a tavern (Athenæ, 13, 21). Athens in the prosperity which she enjoyed during the last fifty years before the Peloponnesian war, might have tolerated the existence, but certainly not the general activity, of such an inquisition.

It appears from the language of contemporary writers, that, while there were any remains of public spirit and virtue in Athens, the council was regarded with respect, appealed to with deference, and employed on the most important occasions (Lys. 'Contr. Theomnest.,' p. 117, 12; 'De Evandr.,' p. 176, 17; 'Andoc.,' p. 11, 32; Dem.

Contr. Aristocr., p. 641-2). In the time of Isocrates, when the dokimasia had ceased, or become a dead letter, and profligacy of life was no bar to admission into the council, its moral influence was still such as to be an effectual restraint on the conduct of its own members (Isocr. 'Areop.,' p. 147). In the corruption of manners and utter degradation of character which prevailed at Athens, after it fell under the domination of Macedonia, we are not surprised to find that the council partook of the character of the times, and that an Areopagite might be a mark for the finger of scorn (Athenæus, 4, 64). Under the Romans it retained at least some formal authority, and Cicero applied for and obtained a decree of the council, requesting Cratippus, the philosopher, to sojourn at Athens, and instruct the youth (Plut. 'Vit. Cic.,' c. 24). It long after remained in existence, somewhat superior in dignity, and perhaps equal in power, to a modern court of aldermen in a municipal corporation. The old qualifications for admission were neglected in the days of its degeneracy, nor is it easy to say what were substituted for them. Later times saw even a stranger to Athens among the Areopagites.

We shall conclude this article with a few words on the forms observed by the council in its proceedings as a court of justice in criminal cases. The court was held in an unenclosed space on the Areopagus, and in the open air; which custom, indeed, it had in common with all other courts in cases of murder, if we may trust the oration ('De Cæde Herodis,' p. 130) attributed to Antiphon. The Areopagites were in later times, according to Vitruvius, accommodated with the shelter of a roof. The prosecutor and defendant stood on two separate rude blocks of stone (Paus. 1, 28), and, before the pleadings commenced, were required each to take an oath with circumstances of peculiar solemnity; the former, that he charged the accused party justly; the defendant, that he was innocent of the charge. At a certain stage of the proceedings, the latter was allowed to withdraw his plea, with the penalty of banishment from his country (Dem. 'Contr. Aristocr.,' p. 642-3). In their speeches both parties were restricted to a simple statement, and dry argument on the merits of the case, to the exclusion of all irrelevant matter, and of those various contrivances known under the general name *paraskue* (παρασκευὴ), to affect the passions of the judges, so shamelessly allowed and practised in the other courts (Or. Lycurg., p. 149, 12-25; Lucian. 'Gymn.,' c. 19). Of the existence of the rule in question in this court, we have a remarkable proof in an apology of Lysias for an artful violation of it in his Areopagitic oration (p. 112, 5). Advocates were allowed, at least in later times, to both parties. Many commentators on the New Testament have placed St. Paul as a defendant at the bar of the Areopagus, on the strength of a passage in the Acts of the Apostles (xvii. 19). The apostle was indeed taken by the inquisitive Athenians to the hill, and there required to expound and defend his new doctrines for the entertainment of his auditors; but, in the narrative of Luke, there is no hint of an arraignment and trial.

Some of our readers may perhaps be surprised that we have made no mention of a practice so often quoted as peculiar to the Areopagites, that of holding their sessions in the darkness of night. The truth is, that we are not persuaded of the fact. It is, indeed, noticed more than once by Lucian, and perhaps by some other of the later writers; but it is not supported, we believe, by any sufficient authority, whilst there is strong presumptive evidence against the common opinion. It was, as it should seem, no unusual pastime with the Athenians to attend the trials on the Areopagus as spectators (Lys. 'Contr. Theomn.,' p. 117, 10). We suspect that few of this light-hearted people would have gone at an unseasonable hour in the dark to hear such speeches as were there delivered, and see nothing. Perhaps there may be no better foundation for the story, than there is for the notion, till lately so generally entertained, that the same gloomy custom was in favour with the celebrated Vehmic tribunal of Westphalia.

ARES (Ἄρης), the god of war and strife among the Greeks, generally considered as corresponding to the Roman Mars. Homer makes him a native of Thrace, and others consider him the father of several Thracian rivers and races. It is therefore highly probable that he was the god particularly worshipped by some northern people, though nearly all other traces of this circumstance have disappeared. The Scythian deity known to Herodotus as the god of war, whom he calls by the Greek term *Ares* (iv. 62), was worshipped under the form of an iron scimitar, to which horses and other quadrupeds were annually offered; and also every hundredth man of captives taken in war. In the later genealogy of the gods he was considered the son of Zeus and Hera (Jupiter and Juno), and, as such, took part in the war against the giants, and slew Mimas and Pelorus. In the contest with Typhon he fled with the other gods into Egypt, and was changed into a fish. He was not more successful in his engagement with Otus and Ephialtes, the children of Aloüs, by whom he was imprisoned for thirteen months. To a still later period we must refer the murder of Halirrhotius, and his trial before the court of Areopagus, as well as his combat with Hercules.

It is a curious circumstance that the Greeks, though constantly engaged in war, should have paid little attention to the worship of Ares. There were few temples erected to his honour in Greece. Geronthræ, a village of Laconia, had a temple and grove where a yearly festival was celebrated, to which no female was admitted (Paus. iii. 22): there was another on the road from Amyclæ to Therapne in Laconia (iii. 19), and a third at Athens (i. 8). Though, as we have remarked, Ares seems to be a Thracian god, yet the element of the word Ares is an integral part of the Greek language, and the word which denoted best and bravest, *aristos* (ἄριστος), is the superlative of *ares*. The Sanscrit *ari*, nom. *aris*, signifies an enemy. In early times human sacrifices were offered to him by the Lacedæmonians, dogs by the Carians, and asses by the Scythians (Apollod. 'Fragm.' p. 394, ed. Heyne).

It is difficult to say what distinctive character ancient artists wished to give to this god, because no Greek state honoured him as their principal deity. We have no distinct account of his statues by Alcamenes and Scopas in the temple at Athens, but we can collect, from some that have been preserved, and also from heads of the god on gems, that the following is the general character under which he is represented. The expression is stern and thoughtful; firm nervous muscles, a strong fleshy neck, and short bristly hair; the mouth is small, the lips full, and the eyes deep-set. It is only in later times that he appears with a strong beard as the Roman Marspiter. He is represented always as a young man in the prime of vigorous strength. When not naked, his dress is a chlamys (*sagum*). See a beautiful head on a gem (Millin, P. Gr. 20); a standing figure on a basso-rilievo (Pio Clem. iv. 7); head on the coins of the Mamertini (Magnani, iv. 31, 32); on the Denarii of Fonteius Capito (Patin. p. 114). In later art he wears only the helmet. In groups he is often figured with Aphrodite. On gems he occurs as the giant-slayer: but in sculpture he is seldom represented as a combatant or engaged in strife. Hirt, 'Bildende Kunst,' 1833; Müller, 'Archäologie der Kunst,' §§ 372, &c.

Mars or *Mavors* (called *Mamers* in the Oscan language), the god of war among the Romans, was regarded by them as identical with the Greek *Ares*, but there can be little doubt he had originally a different origin. He was also called Marspater or Marspiter (Gell., v. 12), and was worshipped in peace under the name of Quirinus, and in war under that of Gradivus. There was a temple in Rome sacred to Quirinus, and another outside the city, in which he was worshipped under the name of Gradivus, on the Appian Way, near the gate Capena (Servius on 'Æneid,' i. 296). Among the Romans Mars was honoured next to Jupiter. According to tradition, Romulus was the son of Mars, by Rea Silvia; and it was perhaps owing to his being the tutelar god of the Romans that the husbandmen were accustomed, according to Cato ('De Re Rust.,' c. 141), to present their prayers to this deity, when they purified their fields by performing the sacrifice called *suovetaurilia*, which consisted of a pig, a sheep, and a bull. He is also called by Cato, Mars Silvanus (c. 83). According to a principle in Roman mythology, by which a male and a female deity are always supposed to preside over the same object of fear or desire, the Romans had a goddess of war called BELLONA.

A round shield (*ancile*), which was supposed to have been the shield of Mars, is said to have fallen from heaven during the reign of Numa, and was entrusted to the care of the Salii, the priests of Mars. Eleven other shields were made like it, in order that it might not be stolen.

The first month (Martius) of the old Roman year, which consisted of ten months only, derived its name from this god.

Mars is generally represented with a beard, but in other respects like the Greek Ares, and is frequently placed in the same group with Rea Silvia. In the Townley Collection in the British Museum, on the base of a candelabrum of Roman workmanship, there is a group of three little figures carrying the armour of Mars, and the helmet borne on the shoulders of one of the figures, is marked in front with the head of a ram, which animal was consecrated by the Romans to Mars as well as to Mercury.

ARGAND LAMP, so called from the name of its inventor, who was a native of France. This lamp has been made of various forms, for the different purposes of reading and of diffusing general light. In the simplest form of the Argand reading-lamp, there is a reservoir from which oil descends gradually to a cistern, and is thence conveyed by a pipe to the burner containing the wick, placed between two tubes and immersed in oil. The wick rises a little above the upper surface of the burner; there is a glass chimney, the lower part of which is enlarged, in order to increase the current of air upwards; the chimney rests on a gallery or stand, where it is kept in its place by four wires. By turning the gallery, the wick is either raised or lowered. The wick is hollow and cylindrical, and receives a current of air both internally and externally; the former enters through open work near the bottom of the burner, and the latter at the gallery: this indeed constitutes the peculiar principle and merit of the lamp. There is a shade surrounding the light, so as to prevent its acting too powerfully on the eyes. Below the reservoir is a handle, which, when the lamp is burning, is depressed, to allow of a supply of oil to descend into the cistern, and which is raised to cut it off when the lamp is not in use. A small cup is screwed below the burner, to receive any drops of oil which may fall. The internal mechanism is thus arranged: The reservoir terminates in a neck, which screws into the upper part of the oil cistern; when it is unscrewed and inverted, the oil is poured into the reservoir through a small hole; by moving a small handle or lever, a short tube is made to cover this hole and prevent the oil from running out, and the reservoir is then screwed into its place, and the handle depressed so as to uncover the hole and to allow the passage of the oil into the cistern. Within the perpendicular tube of the burner there is placed a smaller tube, and both are closed at bottom and open at the top; the space between these contains oil and the wick, stretched over a short tube which rises a little above the other tubes. The outer surface of the inner tube has a spiral groove formed round it; and a tooth in the ring or gallery entering this groove, when it is turned round, causes the tube and wick attached to it to ascend or descend, so as to regulate the flame. On account of the nature of the reservoir which contains the oil, a constant supply will be kept up at the proper level, both in the cistern and in the wick-tubes.

It has been mentioned that various forms are given to the Argand lamps. In those employed for the purpose of giving a general and diffused light, the reservoir of oil is circular, and surrounds the cistern and wick, and is nearly on a level with the latter; a ground-glass shade, which in the smaller lamps is frequently globular, and in larger ones rather flat, rests upon a groove.

The chemical Argand lamp is a very useful instrument—comprising a reservoir of oil; an opening at which the oil is poured into it; a short copper chimney; a pinion by which motion is given to a rack, so as to raise or depress the wick; apertures to supply air; and a dish, in which the lamp stands, to retain any oil which drops from the reservoir.

It will be seen, from the above description, that in the Argand lamp the wick, and consequently the flame also, is in the form of a hollow cylinder, through the interior of which a current of air is made to ascend, in order to afford a free supply of air to the interior as well as to the exterior of the flame; and thereby to ensure more perfect combustion and greater brilliancy of light than could be obtained either by the use of a single large wick, or by a series of small wicks arranged in a straight line. These objects are more perfectly attained by the addition of a glass chimney, which confines the air immediately surrounding the flame, and produces an upward current, which causes it to rise high above the wick. The principle is also extensively applied to gas-burners.

Mr. Hemmenway took out an American patent in 1841, for a means of avoiding the necessity of removing the oil-chamber when an Argand lamp is to be replenished with oil. The fountain or reservoir is to be supplied with oil by a short pipe at the top, which is hermetically closed by a leather valve and screw cap; and between the bottom of this reservoir and the pipe that conducts the oil to the burner is an air chamber, which is supplied with air by a tube passing up through the oil reservoir. This air is made one of the means of filling the vessel with oil.

Messrs. Bedington and Docker registered an improvement in 1849, whereby an Argand lamp is enabled to maintain a clear light for a greater number of hours than under ordinary circumstances. The central air-tube, instead of terminating, as in the usual Argand lamps, nearly on a level with the top edge of the perforated air-cone, is carried about half an inch higher, and has apertures made near its upper end. The outer case is also prolonged at top to a similar extent, and is similarly perforated near the top. By this arrangement currents of air are directed through the apertures into the wick, just below the point of inflammation, and thus the oil is prevented from becoming thickened or carbonised at that spot, a result so likely to occur in the ordinary form of Argand.

In 1858 a new burner was patented, to produce steady flame and complete combustion without a glass chimney. A central ring of orifices is surrounded by an additional ring of lesser orifices, equidistant from the central row and from each other. The object is, that the outer row of jets may obviate flickering and smoking.

Many other improvements have from time to time been introduced in the Argand lamp; and our manufacturers, within the last few years, have shown how much external beauty as well as practical convenience may be imparted to these contrivances.

The name of Argand having become associated with the means of producing a bright light by a judicious arrangement of air-holes, it has been applied not only to lamps, but also to candles and furnaces. During more than forty years, attention has from time to time been directed to the possibility of producing Argand candles—that is, candles constructed on the Argand principle. As, in the Argand lamp, air is supplied *within* the circle of the flame, so it has been thought that if air could ascend through the wick of a candle, the flame produced would be more brilliant. Many varieties have been tried, and some of them patented; but none of them have yet become permanently and commercially successful.

The designation Argand Furnace has been lately given to an arrangement in which a stream of air is made to mingle with the inflammable gases in the furnace, but is previously divided into a number of minute streamlets by passing through small apertures. The principle has been known and partially acted on for a considerable time, but it was brought into a practical form a few years ago by Mr. Williams.

Other contrivances, partaking more or less of the principle of the Argand lamp, are described under LIGHTS, ARTIFICIAL.

ARGEII, a name sometimes applied by Homer to the whole body of Greeks assembled at Troy; it is derived, probably, from the inhabitants of Argos, who had even in those early times raised their city to considerable celebrity. Homer, indeed, employs the word Argos not only to designate the name of a town, but also the whole Peloponnesus: Agamemnon is styled the sovereign of all Argos and the islands (See Strabo, viii. 369.) The capital of Agamemnon's kingdom of Argos, which certainly did not comprise all the Peloponnesus, was Mycenæ. Homer often qualifies it with some epithet, as Achaiicum ('Iliad,' ix. 141), when Argos of the Peloponnesus is meant, and Pelasgicum when the Thessalian city or district of that name is intended. Strabo (viii. 372) tells us that in later times the word Argos in the Thessalian and Macedonian dialects signified a plain or field, and we may therefore perhaps consider it as having the same root with *ager* in the Latin language. What connection this has with the several cities named Argos, the geographer does not think proper to inform us, though he may perhaps intend us to infer that they were so called from being situated in a plain. Pausanias (viii. 7) mentions a plain (called the πεδίον ἀργὸν) close to the mountain Artemisium, but we doubt if this has any reference to the use of the word Argos, of which we are here speaking. The early inhabitants of the Peloponnesian Argos and of the district around it were, we have good reason to believe, Pelasgi. (Strabo, viii. 371; Eurip. 'Orest.,' 931; Æschyl. 'Suppl.,' 268.) The arrival of Danaüs from Egypt, according to tradition, caused their name to be changed to Danaï, a term that occurs in the 'Iliad,' but the mass of the population no doubt still remained the same. Eighty years after the Trojan war, or B.C. 1104, the invasion of the Peloponnesus by the Heraclidæ took place, and Argos, like most of the other cities of southern Greece, was obliged to submit to the Dorians. Still this was only a change of dynasty, and all the older Achæan inhabitants were not compelled to leave their country. From this time the names Argos and Argeii lost their more extensive signification; but the city Argos itself continued an important place under this new race. [ARGOLIS, ARGOS, and ACHÆI, in the GEOG. DIVISION.]

ARGE'NTEUS CODEX, or Silver Book, the name given to a very curious manuscript, or rather fragment of a manuscript, containing the greater part of the Four Gospels in the Mœso-Gothic language, preserved in the library at Upsala, in Sweden. It is believed to be a relic of the Gothic Bible, all or the greater part of which was translated by Ulphilas, bishop of those Goths who were settled in Mœsia and Thrace, and who lived under the emperor Valens about A.D. 360. This curious fragment was discovered in the library of the abbey of Werden, in Westphalia. The leaves are of vellum, some purple, but the greater part of a violet colour; all the letters being of silver, except the initials, which are of gold. These letters, which are all capitals, appear not to have been written with the pen, but stamped or imprinted on the vellum with hot metal types, in the same manner as book-binders at present letter the backs of books. This copy is judged to be nearly as ancient as the time of Ulphilas, or at least not later than a century or two after.

Michaelis and one or two other learned men have opposed the current opinion, that the Silver Book contains part of Ulphilas's Gothic version, and have offered arguments to prove that it is rather a venerable fragment of some very ancient Francic Bible: but they have been confuted by Knittel and others. The letters used in the Gothic Gospels, being twenty-five in number, are formed, with slight variations, from the capitals of the Greek and Latin alphabets, and are believed to have been really the invention or application of Ulphilas. See the notes to Bishop Percy's 'Translation of Mallet's Northern Antiquities,' vol. i. p. 366.

Palimpsest fragments of this Gothic version of the Scriptures, though not in the silver character, have been since found in other places. Knittel printed a fragment, containing part of the Epistle to the Romans, which was discovered in the library at Wolfenbuttel: it was reprinted in 1763, by Professor Ihre; and again in the Appendix to Lye's Saxon Dictionary. In 1819, some further fragments were published by Angelo Mai and Car. Oct. Castillonei, in 4to, at Milan, containing small portions of Esdras and Nehemiah, parts of the 25th, 26th, and 27th chapters of St. Matthew, of St. Paul's Epistles to the Philippians, Titus, and Philemon, and of a homily and calendar; these were discovered in separate leaves in the Ambrosian library at Milan.

The Gothic Gospels of the Silver Book were first printed in types approaching to a fac-simile, by Junius, in 1665; again in common type at Stockholm, in 1671; by Mr. Lye at Oxford, in 4to, 1750, with a Gothic grammar prefixed; by Zahn, 4to, Weissenfels, 1805; by Massmann, 4to, Munich, 1834; by Gabelentz and Löbe (with a glossary and grammar, and the palimpsest fragments of Mai), 3 vols. 4to, Leips. 1836-47; and by Uppström, 4to, Upsala, 1854.

A 'Dissertation on the Argenteus Codex,' by Ericus Sotberg, printed at Stockholm, in 1752, contains two of its pages in fac-simile. Knittel and Mai have also engraved some of the palimpsest fragments which they respectively published.

ARGO, the ship, a southern constellation, the greater part of which, containing all the more important stars, is not visible in this country. It has one star of the first magnitude, CANOPUS (which see). The part of it which is visible in our latitude may be found in and above a line drawn through Orion's belt, and continued beyond Sirius. The star Cor Hydræ is just above the end of the mast, and the direction of the mast is that of a line passing through Regulus and Cor Hydræ. The latter comes on the meridian at six in the evening in the middle of May.

The principal stars in Argo are as follows :

Character.	No. in Catalogue of Lacaille.	No. in Catalogue of British Association.	Magnitude.

μ	4461	3702	3

Owing to the extent of this constellation, it is usual to subdivide it into four regions. They are named as follows: Argo, Argo in Carina (in the keel), Argo in Puppi (in the stern), Argo in Velis (in the sails).

ARGOL. [TARTARIC ACID.]

ARGONAUTS, a term signifying the crew of the Argo, or members of the Argonautic expedition. This is one of the most remarkable of those mythological tales in which, as in the legends of the Trojan war, and the war of the Seven against Thebes, there is reason to believe that a substratum of truth exists, though overlaid by a mass of fiction. Anterior to these events (it is placed by Newton B.C. 937, by Blair B.C. 1263), the Argonautic expedition has a larger share of what is purely fabulous; the licence of the poet being of course curtailed in proportion as the events which he related came nearer to his own times. No story has been more frequently treated by Grecian writers. We shall give a brief outline, and then offer a few remarks upon it.

Jason, the son of Æson, king of Iolcos in Thessaly, having been defrauded of his father's kingdom by his father's brother Pelias, in hope of recovering his paternal inheritance, undertook to bring from Colchis the golden fleece of the ram which carried Phrixus thither. Argus, the son of Phrixus, by the help of Athene (Minerva), built the ship Argo, of fifty oars, at Pagasæ, and it was manned by the most celebrated heroes of Greece, in number fifty. The lists differ, for every state in later times wished to include its own national hero among them; but by general consent the most distinguished warriors, as Heracles (Hercules), the Æacidæ, the Dioscuri, Orpheus, Theseus, &c., were on board the vessel, which was steered by Tiphys, the son of Agnius. Embarking from Iolcos (or, some say, Aphetæ, *departure*), they steered first to Lemnos; thence to Mysia, where Hercules remained behind, seeking his favourite Hylas, who had been carried off by the Naiades, and drowned. (See Theocr. 'Idyll.' 13.) They touched next at Bebrycia, where Amycus, king of the country, was slain by Polydeukes (Pollux), in boxing with the *cestus*, or weighted glove. (Theocr. 'Idyll.' 22.) Apollonius next conducts them to the coast of Bithynia, where Zetes and Calais, the winged sons of Boreas, delivered the seer Phineus from certain winged monsters called Harpies, and in return he gave the Argonauts instructions for the conduct of their voyage. ('Apoll. Rhod.' ii. v. 178-425.) The entrance to the Euxine sea was fabled to be closed up by certain rocks, called *Symplegades*, *clashers*, or *Planktai* ('Od.' xii. 61), or *Cyanean*, which floated on the water, and when anything attempted to pass through, came together with such velocity that not even the birds could escape. Phineus advised them to let fly a pigeon, and to venture the passage if the bird got through safe. It passed, with only the loss of its tail; and the Argo, favoured by Juno, and impelled by the utmost efforts of its heroic crew, passed also, though so narrowly that the meeting rocks carried away part of her stern-works. Thenceforward they remained fixed. The expedition reached the river Phasis without any more adventures worthy of notice. Æetes, king of Colchis, hearing from the strangers the cause of their arrival, promised to give Jason the golden fleece, which was suspended on a tree in the sacred grove of Ares, on condition of his yoking two bulls with brazen feet, which breathed flames, ploughing a piece of land with them, and sowing part of the teeth of the serpent slain by Cadmus, which had the peculiar property of producing a crop of armed men. These difficult tasks he performed by the help of the celebrated sorceress Medea, daughter of Æetes, who fell in love with him, placed the fleece, which Æetes ultimately refused to surrender, in his possession, and became his partner in flight.

How the Argo got back to Greece, it is not easy to say; but somehow or other she found her way from Colchis, at the eastern end of the Euxine, to the western extremity of the Mediterranean. Here the Argonauts touched at Æea, the island of Circe (see 'Od.' xii. 69), which by Homer is placed in the westernmost part of the Mediterranean, and by some later writers has been said to be the promontory of Circeum, on the Latian coast. Hence they passed all the wonders of the western world described by Homer; the Sirens; Scylla and Charybdis; Trinakria (Sicilia), the isle of the sun; and Phæacia, or Corcyra. Near Anaphe, one of the Sporades, they narrowly escaped shipwreck, but were saved by Phœbus. They touched at Crete, proceeded to Ægina, thence to Iolcos, where Jason delivered up the fleece to Pelias; after which he sailed to the Isthmus, and dedicated the Argo to Poseidon, or Neptune.

For a full account of the adventures of the Argonauts, see, besides the passages referred to, Pindar, 'Pyth.' IV.; Apollonius Rhodius; the Orphic Argonautica; Diodorus, book iv. c. 40; see also Hesiod. 'Theog.' 992; Ovid, and the Latin poem of Valerius Flaccus, entitled 'Argonautica.'

The reader will readily understand that it was a difficult matter to get the Argo home from Colchis to Greece, by way of the Mediterranean. Besides numerous large streams, two very great rivers, the Ister and Tanais (Danube and Don), flowed into the Euxine sea, from the west and north-east respectively, in addition to the Phasis (Faz), which entered it on the east side, within the limits of Colchis. Of none of these did the early Greeks know either the rise or course; and this was convenient, for they could do as they liked with them. Pindar ('Pyth.' iv. 44 and 448) conducts the Argonauts into the 'Red Sea' (probably the Indian Ocean), and by the ocean to the coast of Libya, where they carried their ship over land for twelve days, and launching her into Lake Tritonis, entered the Mediterranean. According to the tradition preserved by Herodotus (iv. 179), Jason was driven off the south coast of the Peloponnesus into the shallows of the Lake Tritonis, while he was on his voyage (apparently before the commencement of the great expedition) to carry a hecatomb and a brazen tripod to the god of Delphi. He only got out of the difficulty by surrendering the tripod to Triton, the god of the lake, who on no other terms would consent to pilot him out. Hecatæus of Miletus improved the story, by making them sail from the ocean down the Nile, into the Mediterranean. Pisander and Timagetes, followed by Apollonius Rhodius, carried them up the Ister, and down one of its branches, by which they perhaps meant the Rhone, into the Keltic or Tyrrhene sea. Timæus and others took them up the Tanais to its source, from which they dragged the Argo to an unnamed stream, which carried them to the ocean, and they sailed home by Gades (Cadiz), that is, the straits of Gibraltar. The poet who writes under the name of Orpheus took them up the Phasis, down another branch of it to the Palus Mæotis, at the head of which they entered a river, probably the Tanais, and crossed the Rhipæan mountains to the Cronian or Baltic sea. They passed by the land of the Cimmerians, and the isle Iernis (Ireland?), and home by the strait of Tartessus (Gibraltar) into the Mediterranean.

The gross geographical ignorance involved in each of these routes need not be pointed out. Why later writers should have laboured to solve such an impossible problem it is hard to say, except that Homer brings the Argonauts into the Mediterranean ('Od.' xii. 70), and they may have thought themselves bound to follow him. Diodorus however takes them quickly home by the Euxine Sea.

The name of Minyans, which was given to the Argonauts, according to the mythologists, because most of them were descended from Minyas, son of Poseidon on the maternal side, has led Mr. Keightley ('Mythology') to suggest that the expedition may have been in fact undertaken by the Minyans, an early race in Greece, probably a branch of the Æolian tribe, who inhabited the southern part of Thessaly, and whose port was Iolcos, and their dockyard Pagasæ, and who are conjectured to have been a wealthy and commercial race. (Müller's 'Orchomenos;' and Buttmann's 'Mythologus,' ap. Keightley.)

Mr. Keightley further suggests, that the voyage may in fact have been to the west, for the wool and gold of Spain, and that this explains the universal agreement of all writers in bringing the Argonauts home by the Mediterranean; while at the same time the commodities for which the voyage was undertaken might readily be mythologised into the legend of the golden fleece. We prefer however the simpler belief of Mitford and others, that the expedition was of a piratical nature, on a large scale; in which, according to the notions of honour of the age, a number of young men of the highest rank and spirit engaged under one celebrated leader. The notion of the expedition being a western one seems to be untenable: the bold attempt of exploring the Black Sea, with the mingled objects of plunder, curiosity, and traffic, appears to be a more natural story. (See Herod. i. 2.) As to the Argonauts being found in the western part of the Mediterranean on their return, this notion arose, as we have already intimated, from the ignorance of the later Greeks as to the true course and character of the great streams which enter the Euxine or Black Sea on the north. When the geographers of Strabo's time (Strabo, 'Casaub.' p. 121) could believe, in opposition to the earlier statement of Herodotus, that the Caspian lake was an inlet or bay of the ocean running southward into the land, we may easily conceive how the ignorance of a previous age connected the Euxine with the waters of the ocean. When the Euxine was explored, so as to leave no doubt of its true character, ignorance and credulity merely transferred the same hypothesis to the Caspian. The wanderings of Io, as given in the 'Prometheus' of Æschylus, are a good sample of poetical geography, which may be compared with that of the Argonautic voyage.

Bryant, in his learned work on ancient mythology, considers this expedition of the Argonauts as one of those corrupt traditions in which the recollection of the Deluge, and the preservation of mankind in the ark, was long maintained. Jason, therefore, he believes to be the arkite deity, and the name of Argo to be connected with and derived from the ark itself. The reader will find this question discussed with great research and ingenuity in his 'Ancient Mythology;' but the author's prejudices in behalf of one favourite theory are so strong, that his arguments require to be examined with more than usual care.

ARGOSIE, a ship of great burden, whether for merchandise or war. Shakspere, in his 'Merchant of Venice' (act i. scene 1), says—

"Your mind is tossing on the ocean,
There where your *Argosies* with portly sail,
Like signiors and rich burghers on the flood,
Or as it were the pageants of the sea,
Do over-peer the petty traffickers."

It is mentioned in the same sense by Chapman, Drayton, Beaumont and Fletcher, and other writers. In Rycaut's 'Maxims of Turkish Polity,' chap. xiv., it is said, "Those vast carracks called Argosies, which are so famed for the vastness of their burden and bulk, were corruptly so denominated from Ragosies;" that is, ships of Ragusa, a city and territory on the Gulf of Venice, then tributary to the Porte. We have no proof however that the Ragusan vessels were particularly large; and it seems more likely that the Argosie derived its name from the classical ship Argo. Indeed, Shakspere himself has hinted as much in the play just quoted, when he makes Gratiano, in allusion to Antonio's argosie, say (act iii. scene 2)—

'We are the Jasons; we have won the fleece."

Sandys, in his 'Travels,' p. 2, applies the term argosie to a ship of force. Describing the boldness of pirates in the Adriatic, he observes, that from the timorousness of others, they "gather such courage that a little frigot will often not fear to venture on an argosie."

ARGUMENT, in astronomical tables, is the angle on which the tabulated quantity depends, and with which, therefore, in technical language, the table must be *entered*. If, for example, a table of the sun's declination were formed, corresponding to every degree, &c., of longitude, so that the longitude being known, the declination might be found opposite to it in the table, then the longitude would be made the *argument* of the declination.

ARIA. [AIR.]

ARIADNE, one of the group of small planets revolving between Mars and Jupiter. [ASTEROIDS.]

ARIADNE, according to Apollodorus, was the daughter of Minos and Pasiphaë. Having become enamoured of Theseus, she provided him with a sword with which he slew the Minotaur, and the thread clue by means of which he found his way out of the labyrinth. Theseus carried Ariadne with him from Crete to the island of Naxos, or Dia, where, according to Homer, she was killed by Artemis ('Odys.' xi. 324). But other accounts make him to have abandoned her there, after she had borne him twin sons, Oenopion and Stapylus. Dionysus (Bacchus), according to this version of the story, saw her, and, enchanted by her beauty, raised her to a place among the immortals, and made her his wife. Ariadne was a great favourite with the Greek artists, who represented in her the type of human female loveliness. She is usually seen crowned with ivy and fully draped. On vases, cameos, gems, &c., she is figured as meeting with or forsaken by Theseus; along with Dionysus in a chariot, or accompanied with Erotes, Bacchantes, &c. There is a very fine statue in the British Museum (Third Græco-Roman Saloon), of a female draped in a long tunic and peplus, and crowned with ivy, which is described in the official catalogue as a 'Libera, the female Bacchus, or perhaps Ariadne,' but which Müller ('Archäologie der Kunst,' § 388) without hesitation calls an Ariadne.

ARIANS, a name applied in common to all who entertain opinions concerning the relations between Jesus Christ and the Father similar to those entertained by Arius, although they have not always derived their notions from him. According to the second oration of Athanasius against the Arians (§ 24), Eusebius of Nicomedia, Asterius, and Arius, agreed in the following opinion: God being willing to create the universe, and seeing that it could not be subject to the working of his almighty hand, made first a single being whom he called Son, or Logos, to be a link between God and the world, by whom the whole universe was created. (Compare Athanas. 'Orat. c. Arian.' i. § 5.) The Arians formed a more exalted idea of Christ than the Socinians and the modern Neologians, or Rationalists, in Germany. According to the Rationalists, Jesus was a sort of Socrates among the Jews, and Socrates was a Grecian Jesus. But the Arians did not deny that Christ, in the New Testament, was called God, and they ascribed to him a sort of divine dignity; but asserted that he had this dignity, not by his own essence, but merely by the grace of God the Father. (Athanas. 'Orat. c. Arian. i. § 6.) The Arians fully admitted the incomprehensibility of God, and that Christians ought to pay divine worship to Jesus Christ. This they proved from Christ's saying, "That all men should honour the Son, even as they honour the Father. He that honoureth not the Son, honoureth not the Father who hath sent him." (St. John, v. 23.) Hence the Arians were accused by Athanasius of idolatry, because, according to their own notions, they offered to a creature that tribute which belonged to the Creator alone. The Arians distinguished the Logos in God from the Logos improperly so called.

These were the characteristic doctrines of the strict Arians. But in the western part of the Roman empire, all adversaries of the doctrine of Athanasius, that the Son was *homoousios*, or of the *same* essence with the Father, were called Arians; although some of these opponents taught a doctrine which had already been propagated in the school of Origen, namely, that the Son was *homoousios*, or of *similar* essence. These, afterwards called semi-Arians, were first compelled, by the opposition of the Homoousiasts, to join the Arians, but, owing to the persecutions which they suffered from the strict Arians (who asserted the Son to be *ἀνόμοιος κατ' οὐσίαν, dissimilar in essence*), they were driven back into the orthodox church. The party of Aëtius, and of his pupil, Eunomius, went a step farther than Arius, by asserting the comprehensibility of the divine essence, and by considering the *precision of doctrine* (*δογμάτων ἀκρίβεια*) of chief importance in Christianity. The Antiochene church, under the Arian bishop Eudoxius, afforded an asylum to the ultra-Arian followers of Eunomius. The difference between Arians and semi-Arians became more evident from these extreme opinions, and contributed to the gradual assimilation of the latter to the orthodox church. This assimilation was easily effected, because the semi-Arians had constantly used an orthodox phraseology, which was taken by the people in an orthodox sense. According to Hilarius Pictaviensis, 'Contra Aurentium' (§ 6), the ears of the people were holier than the hearts of their priests. At Constantinople, however, a dogmatising spirit pervaded all ranks of society. Of this we have a graphic description in the 'Oratio de Deitate Filii et Spiritus Sancti,' by Gregorius of Nyssa (Opp. t. iii. p. 466). "The town is full of those who dogmatise concerning incomprehensible matters,—they are in the streets and markets, among the clothiers, money-changers, and victuallers. If you ask any one how much you have to pay, they dogmatise about being begotten and not being begotten. If you ask the price of bread, the reply is, 'The Father is greater than the Son, and the Son is subordinate to the Father.' If you ask, 'Is the bath ready?' the answer is, 'The Son is created from nothing.'" Compare Neander's 'Kirchengeschichte,' b. ii. pp. 767-904.) [ARIUS, in BIOG. DIV.]

ARICINE. [CINCHONA, ALKALOIDS OF.]

ARIES (constellation), the Ram, is the first constellation of the ancient zodiac. The sign of the zodiac, so called, including the first thirty degrees of the ecliptic, reckoning from the vernal equinox, owing to the precession of the equinoxes, now begins in the constellation Pisces.

The Greek mythology makes Aries to be the commemoration of the golden fleece, in quest of which the Argonautic expedition was undertaken. Owing to the difficulty of separating any account of discussions relating to the origin of this constellation in particular, from the general description of the ZODIAC, we refer to the latter term for further mythological elucidation.

This constellation is surrounded by Cetus, Taurus, Perseus, Andromeda, and Pisces, the first of which is directly below it. In the horns are two stars, α and β, the only two of any note, which are near together, and may be found by continuing the line drawn from Procyon through Aldebaran; or, by continuing the line drawn through the pole star, and ϵ Cassiopeiæ, the nearest to the Great Bear of the five. These stars (α and β Arietis) are on the meridian at midnight in the middle of October.

The following are the principal stars in this constellation:

Character.	No. in Catalogue of Flamsteed.	No. in Catalogue of British Association.	Magnitude.
β	6	577	3
α	13	648	2
..	35	831	4
..	39	861	4
..	41	872	3
δ	57	986	4

ARIETTA in music (the diminutive of the Italian word *aria*), a short air.

ARIMA'NES and AREIMA'NIOS are Greek corruptions of the Persian name Ahriman or Aheriman, which, according to the ancient doctrine of Zoroaster, is the appellation of the author of evil and the opponent of Ormuze, who is the author of good. The general form of the word, as it occurs in the original text of the Zend-Avesta, is Anra Mainyu (pronounce Ahroman), a compound term, the meaning of which might be expressed by perhaps an etymological equivalent in the Greek *ἀγριομενής*, "hostile, of evil disposition." The Zend original of the word Ormuzd is Ahuro-Mazdâo, coming near the forms Oromazes and Oromasdes, under which the name occurs in Greek authors (for example, Plutarch, 'De Iside et Osir.' p. 660, ed. Steph.) In the Sanscrit paraphrase of a portion of the Zend-Avesta by Neriosengh, the name Ahur-Mazdâo is interpreted "the king of great wisdom." This interpretation is adopted by M. Eugène Burnouf, 'Commentaire sur le Yaçna, vol. i. p. 72, &c., and Dr. H. Brockhaus, in his 'Heiligen Schriften Zoroasters,' Leipzig, 1840.

The two individual beings, Ormuzd and Ahriman were, according to the 'Zend-Avesta,' the offspring of Zeruane-Akerene, the indefinite and impersonal divine substance and cause of all existence. Both were primarily equal in intellect and power; but Ormuzd was, from the beginning, pure, good, and luminous; while Ahriman was dark and wicked, and bent on destruction and mischief. Ormuzd is represented as the creator of the world: Ahriman constantly counteracts the designs of his goodness. Ormuzd created the six Amshaspands, or ministering angels of good: Ahriman, in opposition, created the six Deeves, to be subservient to his evil purposes. "I produced a place of delight," says Ormuzd, who relates the matter to the holy Zoroaster; "for had I not, the whole inhabited world would have gone to Airyana-vaejo," (wo nirgends geschaffen was eine Moglichkeit;) "but this which I created first was not the best. The second was by the man-ruining Agra-maingus." This second creation was full of death, where there are great snakes, ten winter months, and only two summer months. They create in turns different and opposed places of delight and suffering, but they all appear to have reference to known existing countries. In the one division is found unbelief, labour, and poverty; in the other, beautiful towns, with banners, and full of houses. This is from the first chapter of the 'Vendidad.' The subsequent chapters contain further conversations, with moral precepts and directions for prayers, by which "praising the highest purity," the Deevas are to be expelled, adding, "Long sleep, men, is not fitting for you. Turn towards the three good things, good thinking, speaking, and acting; and from the three bad things, evil thinking, speaking, and acting." Thus Ormuzd is always taking the lead by pure and good productions, and Ahriman follows, sowing the seeds of natural and moral evil in the new creations. Mithra, who is of a later introduction, was the mediator between Ormuzd and his creatures. The struggle of the two deities will, according to the doctrine of Zoroaster, continue during 12,000 years, after the lapse of which Ormuzd will defeat his opponent. Ahriman himself will then become a convert to truth and goodness, and a new world, happier and better than the present, will be created. Plutarch gives similar details, but fixes the period of contest at 3000 years.

The Persian doctrine of the two opposite principles was known to Aristotle, who, according to Diogenes Laertius ('De Vit. Philos. Procem.' 2), distinguished them as ἀγαθὸς δαίμων and κακὸς δαίμων.

The most ancient foreign authors that have given some interesting details regarding the doctrine of Zoroaster are the Armenian chroniclers of the fifth century, especially Elisæus and Esnac. See Elisæus's 'History of Vartan,' &c., translated by C. F. Neumann, London, 1830, 4to, and an extract from the Chronicle of Esnac, in the appendix to P. Aucher's 'Grammar, Armenian and English,' Venice, 1819, 8vo, p. 198, &c.; M. Anquetil du Perron, the 'Zend-Avesta;' but his translation, though valuable at the time, has been found too loose and too often incorrect to allow of the true doctrines of the ancient Persian faith to be drawn from it. Westergaard has published the text of the 'Zend-Avesta,' Copenhagen, 1854; and Dr. F. Spiegel, a translation in German of the 'Vendidad,' which is a portion of it, in Leipzig, 1852.

ARIO'SO, in music (an Italian adjective, *airy*), used to signify 'in the manner of an air,' as contradistinguished from recitative. When applied to instrumental music, it denotes a sustained, a vocal style. It is sometimes, but improperly, used substantively.

ARISTO'CRACY, according to its etymology, means a government of the *best* or *most excellent* (ἄριστοι). This name, which, like *optimates* in Latin, was applied to the educated and wealthy class in the state, soon lost its moral and obtained a purely political sense: so that aristocracy came to mean merely a government of a *few*, the rich being always the minority of a nation. When the sovereign power does not belong to one person, it is shared by a number of persons either greater or less than half the community: if this number is less than half, the government is called an *aristocracy;* if it is greater than half, the government is called a *democracy*. Since however women and children have in all ages and countries (except in cases of hereditary succession) been excluded from the exercise of the sovereign power, the number of persons enumerated in estimating the form of the government is confined to the adult males, and does not comprehend every individual of the society, like a census of population. Thus, if a nation contains 2,000,000 souls, of which 500,000 are adult males, if the sovereign power is lodged in a body consisting of 500 or 600 persons, the government is an aristocracy; if it is lodged in a body consisting of 400,000 persons, the government is a democracy, though this number is considerably less than half the entire population. It is also to be remarked, that where there is a class of subjects or slaves who are excluded from all political rights and all share in the sovereignty, the numbers of the dominant community are alone taken into the account in determining the name we are to give to the form of the government. Thus, Athens at the time of the Peloponnesian war had conquered a number of independent communities in the islands of the Ægean Sea and on the coasts of Asia Minor and Thrace, which were reduced to different degrees of subjection, but were all substantially dependent on the Athenians. Nevertheless, as every adult male Athenian citizen had a share in the sovereign power, the government of Athens was called, not an aristocracy, but a democracy. Again, the Athenians had a class of slaves, four or five times more numerous than the whole body of citizens, of all ages and sexes; yet as a majority of the citizens possessed the sovereign power, the government was called a democracy. In like manner, the government of South Carolina in the United States of America is called a democracy, because every adult freeman, who is a native or has obtained the rights of citizenship by residence, has a vote in the election of members of the legislative assembly, although the number of the slaves in that state exceeds that of the free population.

An aristocracy therefore may be defined to be a form of government in which the sovereign power is divided among a number of persons less than half the adult males of the *entire* community where there is not a class of subjects or slaves, or the *dominant* community where there is a class of subjects or slaves.

Lord Brougham, in his 'Political Philosophy,' vol. ii., gives a somewhat different definition. He says, "Where the supreme power in any state is in the hands of a portion of the community, and that portion is so constituted that the rest of the people cannot gain admittance, or can only gain admittance with the consent of the select body, the government is an aristocracy; where the people at large exercise the supreme power it is a democracy. Nor does it make any difference in these forms of government, that the ruling body exercises its power by delegation to individuals or to smaller bodies. Thus, a government would be aristocratic in which the select body elected a chief to whom a portion or even the whole of its power should be intrusted." He illustrates this by historical examples, and it is perhaps more in accordance with the general acceptation of the word than the previous definition. England can scarcely be termed an aristocratic government, though far less than the half of its adults have any acknowledged power.

Sometimes the word aristocracy is used to signify, not a form of government, but a class of persons in a state. In this sense it is applied not merely to the persons composing the sovereign body in a state of which the government is aristocratical, but to a class or political party in any state, whatever be the form of its government. When there is a privileged order of persons in a community having a title or civil dignity, and when no person, not belonging to this body, is admitted to share in the sovereign power, this class is often called the aristocracy, and the aristocratic party or class; and all persons not belonging to it are called the popular party, or, for shortness, the people. Under these circumstances many rich persons would not belong to the aristocratic class; but if a change takes place in the constitution of the state, by which the disabilities of the popular order are removed, and the rich obtain a large share of the sovereign power, then the rich become the aristocratic class, as opposed to the middle ranks and the poor. This may be illustrated by the history of Florence, in which state the *nobili popolani*, or popular nobles (as they were called), at one time were opposed to the aristocratic party, but by a change in the constitution became themselves the chiefs of the aristocratic, and the enemies of the popular party. In England, at the present time, aristocracy, as the name of a class, is generally applied to the *rich*, as opposed to the rest of the community: sometimes, however, it is used in a narrower sense, and is restricted to the *nobility*, or members of the peerage.

The word *aristocracy*, when used in this last sense, may be applied to an order of persons in states of any form of government. Thus, the privileged orders in France from the reign of Louis XIV. to the revolution of 1789, have often been called the aristocracy, although the government was during that time purely monarchical; so a class of persons has by many historians been termed the aristocracy in aristocratical republics, as Venice and Rome before the admission of the plebeians to equal political rights; and in democratical republics, as Athens, Rome in later times, and France during a part of her revolution. It would therefore be an error if any person were to infer from the existence of an aristocracy (that is, an aristocratical class) in a state, that the form of government is therefore aristocratical, though in fact that might happen to be the case.

The use of the word *aristocracy* to signify a *class of persons* never occurs in the Greek writers, with whom it originated, nor (as far as we are aware) is it ever employed by Machiavelli and the revivers of political science since the middle ages: among modern writers of all parts of Europe this acceptation has, however, now become frequent and established.

The word *oligarchy* is likewise of Greek origin, and it means, according to its etymology, a government of *a few*. By the Greek historians it is used as synonymous with aristocracy, nor did it convey any offensive meaning; among modern nations, however, it generally has an opprobrious force, and when used, it commonly implies that the writer or speaker disapproves of the government or dislikes the class of persons to which he applies that name.

There is scarcely any political term which has a more vague and fluctuating sense than *aristocracy;* and the historical or political student should be careful to watch with attention the variations in its meaning: observing, first, whether it means a form of government or a class of persons: if it means a form of government, whether the whole community is included, or whether there is also a class of subjects or slaves: if it means a class of persons, what is the principle which makes them a political party, or on what ground they are jointly opposed to other orders in the state. If attention is not paid to these points, there is great danger, in political or historical discussions, of confounding things essentially different, and of drawing parallels between governments, parties, and states of society, which resemble each other only in being called by the same name.

It has been proposed by Mr. Austin, in his work on 'The Province of Jurisprudence,' to use the term *aristocracy* as a general name for governments in which the sovereignty belongs to several persons, that is, to all governments which are not monarchies. There would, however, be much inconvenience in deviating so widely from the established usage of words, as to make democracy a kind of aristocracy; and it appears that the word republic has properly the sense required, being a general term including both aristocracy and democracy, and signifying all governments which are not monarchies or despotisms.

ARISTOLOCHIA, *Medical uses of.* The most valuable of the species is the *A. Serpentaria*, which grows in North America, chiefly in Virginia, and hence is called Virginian snake-root. Though the whole root is used, the rootlets are more powerful than the solid root. These consist of a large portion of woody fibre and gummy matter, which have no virtues, along with some resin, bitter extractive, and a little essential or volatile oil, on which principles its virtues depend. It communicates its properties to water and to alcohol, which are employed as the means of extracting them, by forming an infusion or a tincture. Decoction should never be employed, as the heat drives off the volatile oil.

Its odour and taste resemble valerian, angelica, and camphor. In its action on the human system it most nearly approaches to camphor, but its effects are more permanent. It chiefly influences the nervous system, and seems to act most beneficially in those cases where the capillaries, either from not receiving an adequate supply of blood, or of nervous energy, are incapable of producing upon the blood those changes which form secretions in the glands, the skin, and other secreting surfaces, or which are essential for the maintenance of a sufficient degree of vital action in every part of the body. The diseases or disordered states of the system in which it may be advantageously employed can, therefore, be easily inferred.

In protracted fevers, whether of a continued or intermittent kind, it is often eminently serviceable. In those cases of continued fever, which do not assume a very active character, but run on to a lengthened period, commonly called *low* nervous fever, it is preferable to every other agent, and may either be used alone, or in conjunction with cinchona bark, or some of its preparations. Hence, under the title of Huxham's tincture of bark, it is very much used: but a safer mode of administration is that of an infusion of the serpentaria, to which sulphate of quinine, and orange-peel, or other aromatic, may be added; as recommended under AGUE.

In eruptive or exanthematous fevers, such as small-pox and measles, when the eruption is imperfectly formed or threatens to recede, an occurrence always betokening great danger, and indicating much feebleness in the powers of the system, serpentaria is an invaluable agent.

In the sore throat of scarlet fever, or in other affections of the throat, where gangrene is to be apprehended, from the depression of the vital powers, serpentaria, given internally, and used as a gargle, alone, or with tincture of capsicum, is more likely to prevent so serious a termination than any other medicine. In none of these diseases should it be exhibited till after the bowels have been thoroughly cleared out by proper purgative medicines. But there are other diseases, not attended with fever, in which serpentaria is extremely useful. In that form of indigestion where no inflammatory state of the mucous membrane of the stomach exists, and where the skin is harsh and dry, serpentaria alone, or better with sulphate of quinine, is eminently serviceable. On the same principle, in the state of torpor or exhaustion to which literary persons are subject, from long-continued or intense mental exertion, this combination is highly useful.

In America, the infusion or tincture of serpentaria is sometimes taken every morning in damp aguish situations, to prevent intermittents. It is likewise said to prove useful in the treatment of a kind of pleurisy accompanied with great derangement of the biliary system, of frequent occurrence in autumn, among persons exposed to the exhalations of the marshes in America.

This species, and several others, both in America and the East and West Indies, are much employed as antidotes against the bite of serpents; and hence the name snake-root. Dr. Hancock states, that the quaco, used by the South Americans in such cases, belongs to this tribe.

ARISTOLOCHIN. The name given to a non-azotised bitter principle contained in snake-root, *Aristolochia serpentaria.* Its nature and composition are unknown.

ARITHMETIC, from the Greek ἀριθμητική (*arithmétike*), 'the art of numbering,' should mean the science of numbers in general, including a great part of what is commonly called *algebra*. It is however usually restricted to mean only the science of the expression of numbers by symbols, and the application (not investigation) of all rules relating to them which are useful in the arts of life. Under this general head we shall here confine ourselves to the elucidation, philosophical and historical, of the method of naming and representing numbers; in doing which we shall refer to such other articles as will, all together, furnish the most complete view of the subject our work can afford. For the method of applying principles in practice, see the names of the various rules, ADDITION, SUBTRACTION, &c. For the account of what we must call the psychology of arithmetic, see NUMBER; and for the history of this branch, see PYTHAGORAS, PLATO, THEON, EUCLID, DIOPHANTUS, FERMAT, &c., in the BIOGRAPHICAL DIVISION. For that part of algebra which particularly concerns pure arithmetic, see NUMBERS, THEORY OF. For the arithmetic of concrete numbers, see WEIGHTS and MEASURES, and such articles as YARD, POUND, &c.

All the information possessed on the main points of arithmetical history has been presented to the world in so complete a shape, that it would be little better than affectation to make any more references than one, in an article which has no pretensions to original research. Of course we allude to Dr. Peacock's History of Arithmetic contained in the 'Encyclopædia Metropolitana', which is certainly the most complete treatise yet written on any one point of mathematical history. In using this work as our universal reference, we regret that our limits will not allow us to make such a formal abstract of it, as would oblige us to ask the permission of its owners before we published this number. But as the treatise itself is of a length answering to more than 60 pages of this Cyclopædia, such an account of its contents would be impossible; and we therefore use it only as an authority for citations of fact, in which we shall refer to the paging of the 'Encyclopædia Metropolitana.' We however feel bound to bear testimony to its correctness on all points which our access to books has enabled us to investigate.

We find ourselves in possession of a method of representing numbers so simple and powerful, that the principle and practice of the most complicated rules follow from it with ease. It is so well known that we need not explain it; but when we separate from the rest the part which particularly distinguishes our *Numeration* from that of the ancient Europeans, we shall find that our superiority consists in the adoption of the following conventions:—

1. The value of a figure depends not only upon the simple number for which it stands when alone, but upon the place in which it stands. Thus, in 888, the three eights mean eight, eight tens, and eight hundreds.

2. The place of a figure, considered as affecting its value, is determined by the column in which it stands, and in the absence of succeeding figures to indicate the existence of other columns, their place is supplied by ciphers, which of themselves are considered as having no value. Thus the 8 in 800 is of the same value as that in 863.

To complete our particular system, on which however none of its advantages depend, we must add that each figure is increased *tenfold* for every place which it is removed to the left. In the first two conventions consists what is called the 'local value' of the figures; in the last is found the reason for the term 'decimal notation,' from the Latin word *decem*, ten.

There can be no doubt that the mere decimal notation, which has been in use in almost every age and country, has arisen from the facility which the ten fingers afford for making calculations. The names of numbers have been almost universally formed distinct as far as ten, after which compound names have been employed. The exceptions to the rule are additional proofs of the generality of the principle; they are either deduced from five or from twenty, the number of fingers on one hand, or the number of fingers and toes together. We call the simple symbols of numbers *digits*, or fingers; the Caribbees call the number ten by a phrase which signifies 'all the children of the hand' (Peacock, 390); and in many languages the phrases for five, ten, and twenty are connected, either by direct derivation or common etymology, with those for the hand or fingers. In France the scale from 60 to 100 is strictly vicenary (by twenties), and in the Indian Archipelago the ancient scales are vicenary. For more discussion on this point we refer to NUMERALS. We shall here only quote two results of observation, as laid down by Dr. Peacock (371), which appear to be very well borne out. They are, that "the natural scales of numeration alone have ever met with adoption," meaning, by natural scales, those derived from the hands, or hands and feet; and that "amongst all nations, practical methods of numeration have preceded the formation of numerical language."

But this does not mean that every nation has gone high in the scale of numbers. There are tribes which have never even risen to a *quinary* scale (by fives), owing to their never wanting, and therefore never giving names to, numbers as high as five. Aristotle (P. 391) mentions a tribe of Thracians which never counted higher than four; and the Yancos on the Amazon have been stopped by the complexity of their language. They count no higher than three, the name for which in their language is (P. 390), according to La Condamine, *Poettarrarorincoaroac.*

One of the Abipones, in describing a number of men greater than ten, would mark out a space of ground sufficient to contain them. This is, in its principle, the same resource as that to which the Greeks were driven by their cumbrous notation, namely, the substitution of geometry for arithmetic. [SQUARE; EUCLID, BIOG. DIV.]

To enable our readers rightly to estimate the advantage which we possess in our notation, we will here describe that of the Greeks, which is only equalled by that of the Chinese in its near approach to the Indian, or generally received system, and is very much superior to that of the Chinese in the simplicity of its symbols. We shall omit the substitution of letters for numbers, and content ourselves with abandoning the principle of 'local value,' and substituting in its place such a system of symbols as, without departing from the *principle* of Greek notation, will not confuse the reader by the adoption of new digits. For the actual signs used by the Greeks, see NUMERATION; NUMERALS. Let the first nine numbers be represented as usual, but let *ten* (instead of 10, in which 1 has local value) be represented by 1′, twenty by 2′, &c. Let 1″ be one hundred, 2″ two hundred, and so on; 1‴ one thousand, 2‴ two thousand, and so on. Let M stand for ten thousand, and let M affixed to a number make its value ten thousand times as great; thus, 4′2M is 420,000 in our notation. We have here improved upon the system of the Greeks, unavoidably, in order not to confuse the reader, since 2000, 200, 20, and 2, would not among them present to the eye that analogy which exists between 2‴, 2″, 2′, and 2, being in fact denoted by

$$\beta', \ \sigma, \ \kappa, \text{ and } \beta.$$

We now write some high numbers in our own decimal scale, accompanied by our imitation of the Greek.

46379268	4‴6″3′7M.9‴2″6′8
6007.0030	6‴7M.3′
72007106	7‴2″M.7‴1″6

In the first number, *where there is no cipher*, the Greek looks so like our own that we might be led to imagine there was no essential difference. We might say, that as it would be natural, and was in fact usual, to write the higher numbers first, the mere occurrence of a fourth column would suggest the idea of thousands, so that a notion, which we must call one of *local value*, would be inevitably formed. And perhaps it was so: indeed, it is surprising that neither Archimedes, Apollonius, or Diophantus, ever detected and improved the idea. But when we come to look at the second and third number, we see immediately that the continual derangement of the columns would prevent this notion from acquiring consistence. The symbol of *vacuity* is wanting; and we cannot see how great an impediment that defect presented, because we learn 20, 30, &c., as soon as we learn *twenty, thirty*, &c. And though perhaps 2′, 3′, &c., might have suggested such a contrivance, yet there was no analogy between κ (20) and λ (30) and β (2) and γ (3).

The ingenuity both of Archimedes and Apollonius was employed in the extension of the preceding system, without alteration of its principle. That of the latter we shall imitate. Calling 10,000 M_1, let ten thousand times ten thousand be called M_2, ten thousand times that number M_3, and so on, and let any one of these placed immediately after a number mean that the preceding is to be taken ten thousand times if followed by M_1, ten thousand times ten thousand if by M_2, and so on. The following number,

1768,9360,0142,0193,

would then be represented by

1‴7″6′8M_3.9‴3″6′M_2.1″4′2$M_1$1″9′3,

on which we may make the same remaks as before. The method of Archimedes (which preceded this) differed from it only in making ten million the *radix* of the system. We now see why our arithmetic was called *ciphering*, cipher coming from an Arabic word signifying *vacant*. One such thought as occurred to Archimedes in the bath [ARCHIMEDES, BIOG. DIV.] might have been fourteen centuries gained to the science.

We look in vain for anything like local value in the system of the Egyptians, or any other nation of antiquity who are known with *certainty* to have very ancient records. That of the Jews was similar to the one just described, so far as it went, and the use of some letters common to both (P. 406) in the numeral system, but not so in the *alphabets* of the two, proves that the notation of both had a common source. [NUMERALS.]

To the same article we must also refer for the Roman system, which extended itself throughout Europe during the first twelve centuries. It is much more rude than the Greek, and is a sufficient proof of the well known inaptitude of the former people for scientific invention.

The Chinese had several systems of numeration, all containing complicated symbols, and somewhat resembling that of the Greeks in principle, but with this important difference, that the symbol for 30, for example, has direct analogy with that for 3, being made by the juxtaposition of a symbol for ten; so that the improvement upon the Greek scale which we have been obliged to make in order to explain it, renders our imitation of the Greek a better resemblance of the Chinese. But they have no written method of expressing local value; though their *Schwan-pan* [ABACUS] is a practical use of the principle.

Before we proceed to the history of our own scale, we must extend our remark, that the 'decimal notation' and 'system of local value' are distinct things. When we agree that 10 shall stand for ten, we merely express that a number in the second column from the right shall stand for ten times as much as the same in the first column. But we are at liberty to suppose that a number in the second column shall mean nine, eight, or any other number of times what it does in the first. Thus, if we choose a *quinary* scale, in which 10 stands for 5, we reject the symbols 5, 6, 7, 8, and 9, and our numerical scale runs thus:—

1	2	3	4	10	11	12	13	14	20	21	22	&c.
one	two	three	four	five	six	seven	eight	nine	ten	eleven	twelve	&c.

Thus 20 is *ten*, because 2 in the second column counts five times 2. But if we choose a higher scale than the decimal, we shall have to invent instead of rejecting symbols; if, for instance, we take a *duodenary* scale in which 10 means twelve, we are left without symbols for *ten* and *eleven*. Let *t* and *e* stand for these; then our scale of number, beginning from ten, is as follows:—

t	*e*	10	11	12	13	14	15	16	17	18	19	1*t*	1*e*	20	&c.
ten	eleven	twelve	thirteen	fourteen	fifteen	sixteen	seventeen	eighteen	nineteen	twenty	twenty-one	twenty-two	twenty-three	twenty-four	&c.

But the scale which best exemplifies the principle is the binary, in which 10 stands for 2, and in which there are consequently no symbols except 1 and 0. The system of numbers in this scale (from one to ten) is as follows:—

1 10 11 100 101 110 111 1000 1001 1010.

A Jesuit at Pekin (P. 392) communicated to Leibnitz the following Chinese symbol, called by them the Cova, or *lineation*, and attributed to Fohi, the founder of the empire. It is suspended in their temples, and considered as a mystery:—

If the long line be interpreted to mean *one*, and the broken line *nothing*, these symbols, each being read from the bottom to the top, give a system of binary arithmetic from 0 to 7 (both inclusive). And Leibnitz asserts that there is a larger *Cova*, which goes up to 63. But as no additional information has been obtained upon the subject, which, for anything certainly known to the contrary, may be a hoax, we can only say that there is some presumption that the Chinese long ago possessed the complete principle of the 'local value.'

We trace our own knowledge of the decimal system direct to the Hindoos, who themselves ascribe it to the divinity. As to the manner of its introduction, there are some differences of opinion on that subject. One and the old account is, that Gerbert, after Pope Sylvester II., found it in Spain among the Moors (P. 415) in the latter part of the 10th century. But upon this there are strong reasons for hesitating [SYLVESTER II., BIOG. DIV.] Another and more probable account is, that Leonard of Pisa [BONACCI, BIOG. DIV.; ALGEBRA] introduced it, in 1202, in a work entitled 'Liber Abbaci,' &c.; and some have supposed that the 'Alonsine (or Alphonsine) Tables,' being constructed principally by Moors at the court of Alonso, must have been the first in which the system appears (P. 413). It is certain that this system had been before the 12th century, and most probably as early as the 9th, in the hands of the Persians and Arabs, who ascribe it to the Hindoos, and call it by a name which signifies 'Hindoo science.' It is also certain that the Hindoos themselves have long used it [see VIJA GANITA and LILIWATI, names of Hindoo works], and that it is easy to trace the manner in which our numeral symbols have been derived from those of the Sanscrit. In this latter language there are distinct names for *units, tens*, &c., up to what we should call *hundreds of thousands of millions of millions*. But whether we are to look to a Hindoo for the invention is a question on which no surmise can be made till some probable account of the origin of Hindoo literature can be given.

The steps by which the new notation made its way through Europe are not capable of being very clearly traced. Montfaucon (P. 417) found them in an Italian manuscript which was finished in 1317; and many manuscripts of the works of authors a century older contain them, but it is well known that it was usual to substitute the new figures for the old in recopying. In the library of Corpus Christi College, Cambridge (P. 418), is a catalogue of eclipses from 1300 to 1348, to which they are subjoined. Graven dates on inscriptions have been given by Wallis and others as old as 1330; but, upon examination, reason has been found to suspect that 5 has been mistaken for 3. There does not seem to be evidence of any general use of the Arabic numerals before the invention of printing, and even the works of Caxton do not contain them, except in a woodcut. Merchants continued their accounts in Roman figures up to the 16th century. On the whole, we think that the general use of these numerals in scientific works did not much precede, if at all, the diffusion of algebra.

There has been much argument in favour of the assertion that the principle of local value is of older date in Europe than is commonly supposed, and was known even to the Romans. We suspend our opinion on this unfinished discussion, and refer the reader to the writings of M. Chasles.

The only material addition which has been made to this groundwork of arithmetic is the invention of decimal fractions. This is an extension of the principal of local value, of so simple a character, that it is surprising the Hindoos never adopted it. They write fractions as we do, omitting only the line which separates the numerator and denominator, and they make great use of decimal fractions in approximating to the square roots of numbers, but without any peculiarity of notation.

The first fractional notation which we find among the Greeks consisted in writing the denominator where we now write the *exponent*. Thus, retaining our imitation, $\frac{207}{365}$ would be written $2''7^{3''6'5}$. This system is principally used by Diophantus; and in Eutocius we also find a peculiar symbol, something like κ, for *one half*. Ptolemy made a further step, in the application of the method of dividing the circle to all units whatsoever, known by the name of the *sexagesimal* notation. The degree of the circle is divided into sixty minutes, the minute into sixty seconds, that again into sixty thirds, and so on: Ptolemy divides every unit in the same manner. We have still retained in our division of the circle the ′, ″, ‴, &c., used by him. In the notation alluded to (which is that of Ptolemy in the particular point referred to)

$$27\ 33'\ 21''\ 3'''$$

would denote

$$27 \text{ units}, \frac{33}{60}, \frac{21}{3600}, \text{ and } \frac{3}{216,000}.$$

This sexagesimal notation retained its ground until the introduction of the Arabic numerals, and with the aid of tables of reduction, was of material use.

Stifelius and Stevinus (P. 440) used circumflexed digits instead of ′, ″, &c., in the *sexagesimal* system, and an application of the same principle to the *decimal* system was first made by Albert Girard in or about 1590. This consisted in expressing fractions by tenths, hundredths, &c., in the following way—

$$16\ \frac{3}{10}\ \frac{4}{100} \text{ would be written } 1\ \overset{(0)}{6}\ \overset{(1)}{3}\ \overset{(2)}{4},$$

the number in parentheses over a digit being the exponent of the power of ten, which must be used with that digit as a denominator. Here the application of the principle of local value practically begins; and it is clear, from the examples cited by Mr. Peacock, that the *cipher* was made use of to denote a vacant column. One of those examples is

$$94\overset{(0)}{1}\ \overset{(1)}{3}\ \overset{(2)}{0}\ \overset{(3)}{4}$$

Decimal fractions were slowly introduced into England in the first half of the 17th century, by Wright, Napier, Wingate, Johnson, Oughtred, &c., From that time the modern form of the Indian arithmetic must be considered as established. The invention of LOGARITHMS (which see) is the principal aid to calculation which has been engrafted upon the system.

We subjoin a list of names, which the reader may consult on various points connected with the history of arithmetic, either in this work or elsewhere. The figures refer to the century before or after Christ in which the individual is supposed or known to have lived; and the works cited are in quotation marks.

B.C. 6—Pythagoras. 4—Euclid, Aristotle, Plato. 3—Archimedes, Apollonius. 1—Vitruvius.

A.C. 2—Ptolemy, Diophantus. 3—Nichomachus. 4—Pappus, Theon. 5—Proclus, Eutocius. 6—Boethius. 9—Mahommed Ben Musa. 11—Gerbert. 12—Jordanus, Leonardo Bonacci. 13—Sacrobosco, Planudes. 15—Lucas di Borgo. 16—Scheubelius, Stifelius, Recorde, Albert Girard. 17—Briggs, Napier, Oughtred, Stevinus, Wright, Bouillaud, Mersenne, Wallis, 'Algebra;' Bachet de Meziriac. 18—Weidler, 'Historia Astronomiæ;' Kæstner, 'Geschichte der Mathematik;' Montucla, 'Hist. des Mathématiques;' Delambre, 'Hist. de l'Astronomie Ancienne;' Hutton, 'Tracts,' 'History of Algebra;' Colebrooke, Preface to 'Bija Ganita;' Chasles, various writings; Libri, 'History of Mathematics in Italy.'

We need not of course refer to the work of Dr. Peacock, which we have so often cited.

ARITHMETIC, POLITICAL. [STATISTICS, INTEREST, ANNUITIES, POPULATION, MORTALITY, &c.]

ARITHMETIC OF SINES. [TRIGONOMETRY.]

ARITHMETIC, SPECIOUS. [VIETA.]

ARITHMETICAL COMPLEMENT is that which a number wants of the next highest decimal denomination. Thus what 7 wants of 10, or 3; 32 of 100, or 68; 159 of 1000, or 841; ·017 of 1, or ·983: are the arithmetical complements of these numbers. The best way to find them is to begin from the left, subtract every figure from 9, and the last significant figure from 10, as in the following examples, which include all the cases:—

No.	17634	19·0018	1734000
Ar. Co.	82366	80·9982	8266000

ARITHMETICAL MEAN. By *the* arithmetical mean is meant, that number or fraction which lies between two others, and is equally distant from both. Thus the arithmetical mean between 6 and 14 is 10. To find this arithmetical mean, take the *half sum* of the two numbers. Thus, that of 4 and 17 is $10\frac{1}{2}$. But any numbers are also said to be arithmetical means between two others, when all together form a series of equally increasing or decreasing numbers. Thus, 8, 10, 12, are three arithmetical means between 6 and 14. To interpose any number of arithmetical means between two numbers, divide the difference of those two numbers by one more than the number of means required, which gives the difference between the means. Thus, to interpose four arithmetical means between 27 and 102, divide 75 (102—27) by 5 (4+1) which gives 15. The means are, therefore, 27+15 or 42, 42+15 or 57, 57+15 or 72, and 72+15 or 87. If the means are fractional, the same process is employed. [AVERAGE.]

ARITHMETICAL PROGRESSION is a name given somewhat improperly to a series of numbers which increase or decrease by equal steps, such as 1, 2, 3, &c.; 2, 4, 6, &c.; $1\frac{1}{2}$, 2, $2\frac{1}{2}$, &c. The difference between any two successive terms, being *common* to all, is called the common difference. The *data* which distinguish one arithmetical progression from another, are the *first term*, the *common difference*, and the *number of terms*: from these it is easy to find the last term and the sum of all the terms. To find the last term, multiply the common difference by one less than the number of terms, and add the first term to the product. To find the sum of all the terms; take

the number of terms,
the sum of the first and last,

and multiply the half of either (whichever is most convenient) by the other, or take half the product of the two. Thus, for 100 terms of either of the series

3	6	9	12 . . . . &c.	(A)
1	$1\frac{1}{2}$	2	$2\frac{1}{2}$ . . . &c.	(B)

To find the last, or 100th, term of (A), multiply 3, the common difference by 99 (100—1) and add 3, the first term, which gives 300. Similarly to find the last, or 100th, term of (B), multiply $\frac{1}{2}$ by 99 and add 1, which gives $50\frac{1}{2}$. For the sums we have

	(A)	(B)
No. of terms	100	100
Sum of first and last	303	$51\frac{1}{2}$

Multiply half of 100 by 303, and by $51\frac{1}{2}$, which gives 15150 for the sum of (A), and 2575 for that of (B).

Algebraically, let a be the first term, x the common difference, and n the number of terms. Let z be the last term, and S the sum. Then

$$z = a + (n-1)\,x$$

$$S = \tfrac{1}{2}\,n\ \ (a + z) = na + n\frac{n-1}{2}x$$

from which any three of the letters being given, the other two can be found.

For the theory of which this article is a part, see SERIES, DIFFERENCES, INTEGRATION.

ARITHMETICAL PROPORTION, the relation which exists between four numbers, of which the first and second have the same difference as the third and fourth. Thus:—

1	2	81	82
7	3	16	12
$2\frac{1}{2}$	$3\frac{1}{4}$	$1\frac{3}{4}$	$2\frac{1}{2}$

are severally in arithmetical proportion, and in every such proportion the sum of the extremes is equal to that of the means. Thus:—

$$12 + 7 = 3 + 16.$$

ARK, a chest or coffer. This term is frequently used by our earliest English and Scottish poets.

In 1347, in the brewhouse of the priory of Lindisfarne, was an ark for meal (see Raine's 'North Durham,' p. 92); and among other articles of furniture occurring in an inventory of the household goods belonging to Sherborn hospital, taken in 1636, in the boulting-house, is, '1 boulting ark.' (Hutch. 'Hist. Durh.' ii. p. 599.) The same word is still in use, in the north of England, for the chest which is employed in containing meal.

Noah's ark was so named from its supposed resemblance to an ark or chest; by which name it occurs both in the Gothic and Anglo-Saxon versions of the passage in Luke, xvii. 27. Wiclif, in this passage, instead of ark, reads ship. The same term ark is used in our translation of the Old Testament, for the basket or cradle in which the infant Moses was laid when he was put into the Nile. (See Boucher's 'Glossary,' by Stevenson.)

The ark of the tabernacle is of the same derivation. While travelling in the Wilderness the Israelites bore it in the form of a shrine, though it is said to have been fifty-five feet long, eighteen broad, and eighteen high. When the temple was built, the form was preserved, an oblong square. Into this none but priests were admitted, the people being assembled; and the sacrifices performed, in a court in front, while the sacred apartment was in the innermost recess.

ARMA'DA. This term, which is derived from the Latin word *armata*, 'armed,' and consequently comes from the same root as the French *armée* and our *army*, is used in Spain to denote exclusively a naval armed force, or fleet of war. *Flota* is used in the same language for a fleet of merchant-men. Armado, which occurs in Shakspere's

'King John,' act iii. sc. 4, Sandys's 'Travels,' p. 51, &c. is a corrupted term; so Fairfax, in the translation of 'Tasso,' i. 79.

"Spread was the huge *armado* wide and broad."

Ben Jonson, however, writes it correctly, Armada.

Nares, in his 'Glossary,' thinks that this word was not known in England before the Spanish projected invasion in 1588; and it is now rarely used but in speaking of that particular fleet. An account of it will be found under ELIZABETH, in the BIOGRAPHICAL DIVISION.

ARMATOLI, were originally the mountaineers of Thessaly or northern Greece. On the subjugation of the country by the Turks, they preserved their independence by retreating to the mountains, where they lived practising robbery in the plains, and were known as Klephts. They inhabited the fastnesses of the ranges of Olympus, Pelion, and Pindus. As their marauding was so far from being considered a disgrace that they formed favourite subjects for the national poets (see the 'Chants populaire de la Grèce moderne,' collected by C. Fauriel), it will not sound strange that they were mostly Christians. The sultans, finding great difficulty in reducing them to submission, were constrained to come to terms of pacification with them, and, on the payment of a trifling tribute, they were allowed to retain their arms, and to form themselves into a military community, occupying their native districts, and governed by their own laws. They were charged with the suppression of brigandage in the mountain passes, for which they received a species of tribute. The chiefs were styled Capitani, Polemarchs, or Protatos; the jurisdiction of a chief was called an armatolic, and he resided generally in the principal village of his canton. The office was hereditary, descending to the eldest son, who obtained a diploma from the pacha of his district, to whose authority he submitted. The band was composed of and commanded by Greeks exclusively; and, according to Fauriel, the number of cantons, immediately prior to the revolution, amounted to seventeen. The members who, in point of number, were unrestricted, were called palikari: their costume was that generally known as the Albanian; their arms consisted of a yatagan, sabre, musket, and pistols; they were brave and temperate, and inured to hardship and fatigue.

About the middle of the last century, however, the Porte appointed a Dervenji Bashi, in whose hands the care of all the passes was placed: this was a measure designed for the subversion of the armatoli. Ali, pasha of Joannina, having been also appointed Dervenji Bashi, made strenuous efforts to destroy their independence; but his cruelties drove the greater part to rebellion, and they fled to their native fastnesses, and re-incorporated themselves with the Klephts, being recognised indifferently by either name. Here, and also in the Morea, they maintained a sort of turbulent independence, and, at the first cry of the revolution, which commencing at Patras in 1821 was only ended in 1829 by the establishment of Greece as an independent kingdom, they issued forth to assist in the liberation of their country. After Greece became a kingdom, the Armatoli were chiefly incorporated into the regular army, and though no longer recognised as a class, the old Klephtic spirit is not yet extinct in the Thessalian hills.

ARMILLA, a bracelet, or large ring, for the wrist or arm. The wearing of the Armilla, or bracelet, as an ornament, is of very high antiquity. It occurs in Genesis, chap. xxiv. 22, 23, where Abraham sends his servant to seek a wife for Isaac. The Amalekite who slew Saul (2 Sam. i. 10) "took the crown that was upon his head, and the *bracelet* that was on his arm," and brought them to David.

The Armilla, or bracelet, as a decoration for both sexes, was perhaps the most universal of all ornaments—common to almost every nation, and far more general than the *torques*, or collar for the neck. It was sometimes worn upon the wrist, sometimes near the shoulder, and occasionally upon the ancles. Bartholinus, in his treatise 'de Armillis Veterum,' asserts, that it was of such general use as to be worn even by slaves, when they could obtain permission from their masters. This accounts for the great number of armillæ which have been found, of a slender shape and mean form, in bronze, in different countries once possessed by the Romans. By the Greeks the use of the bracelet seems to have been confined to the female sex; and even in Rome it was looked upon as an effeminacy for men to wear bracelets in ordinary life.

As an ornament of dress, the Armilla is frequently spoken of as massive. Livy (l. i. c. 11) says the golden bracelets of the Sabines were of great weight. Petronius Arbiter (c. 67) speaks of the Roman women as wearing bracelets of six pounds and a half, and even of ten pounds' weight, though the fact seems incredible.

It is not, however, as a mere ornament of dress that we are to consider the armilla; its most important use was as a gift of reward. Ælian ('Hist.' lib. i. c. 22) says the Persian kings rewarded all ambassadors, whether from Greece or other nations, with presents of armillæ. Plutarch, Xenophon ('Anabasis,' i. 2, 27), and Herodian, all allude to them as military or royal gifts.

Livy, in his account of the Samnite war (l. x. c. 44), says that at Aquilonia, Papirius, who had been engaged in various service, in the field, the camp, and the city, gave *armillæ* and coronets of gold to Spurius Nautius, to Spurius Papirius his own nephew, to four centurions, and to a whole band of the hastati. To the horsemen also, as a reward of valour, he gave armillæ and little horns of silver.

The gift of the *golden* armilla, however, was reserved peculiarly for the Roman citizen. Pliny says, to auxiliaries and strangers they give gold torques; to their own citizens only silver. But, exclusive of these, the Roman citizens have armillæ given them, which foreigners have not. ('Hist. Nat. l. xxxiii. c. 10.)

Aulus Gellius, in the eleventh chapter of his second book, describing the exploits of Dentatus, says he was called the Roman Achilles; that he had been in more than a hundred and twenty actions; that he had never received a wound in the back, but that he had five and forty wounds in front; and that among his rewards he had achieved eight golden crowns, one obsidional, and three mural crowns; that he had received eighty-three torques, and more than a hundred and sixty armillæ. ('Noct. Att.' l. ii. c. 11.)

Gruter (Inscript. MXCVI. 4) has preserved a monumental inscription in memory of Lucius Lepidius, who had served in different legions, and received various armillæ, torques, and other ornaments, as rewards, from the Emperor Vespasian. Smetius (fol. lxxiii. b.) gives another, for a soldier upon whom both torques and armillæ had been bestowed by Trajan. Numerous other such inscriptions will be found in the different collections. Brissonius has given the formula of one of these donations: '*Imperator te Argenteis Armillis donat.*'

The draconarii, or standard-bearers, wore armillæ. See Ammianus Marcellinus (l. xx. c. 4), where the soldiers crown Julian with one of them.

There was another use to which the armilla or bracelet was applied from the very remotest ages of the world. It was used as an offering. In the Book of Exodus bracelets are included among the free gifts for the tabernacle.

Offerings of serpentine armillæ, or torques, were also made to Æsculapius.

Gifts of armillæ, however, were not confined to the warriors of Greece and Rome. The practice was as prevalent in the remoter regions of the north. The fragments which remain of the compositions of the Scaldic bards are full of allusions to the gift of bracelets. Snorro Sturleson's History affords ample proof of this. Hrolf Krake, King of Norway, whose reign is ascribed to the 5th century, is mentioned as bestowing them by Saxo Grammaticus. ('Hist. Dan.' ii. p. 29.) In the 'Saxon Chronicle,' under the year 975, the English Edgar is expressly called be oꞃnabeah-ᵹyꞅa the *bestower of bracelets*, the rewarder of heroes; a term, indeed, usual as an epithet for a great chieftain in most of the Saxon poems. It occurs no where more frequently than in the song of the Traveller, and in the well-known poem of Beowulf.

Nor were armillæ gifts of reward made in person only; we find them frequently mentioned as legacies in the Saxon wills. In the will of Brihtric and his wife Ælfswytha (he was one of the Thanes of Archbishop Ælfric), preserved in the Textus Roffensis, among the articles which formed a legacy to the king, we have a bracelet of gold of the weight of eight mancuses; and to the queen a bracelet of thirty. In the will of Wulfer, which follows the will of Brihtric in Dr. Hickes's 'Thesaurus,' we find a legacy of a bracelet of sixty mancuses. ('Dissert. Epist.' p. 51.) William of Malmesbury informs us, that when Earl Godwin made his peace with Hardiknut, in the year 1040, he sealed it by a magnificent present—a ship, whose stern was richly ornamented with gold; and within it, eighty soldiers, each clothed in the most sumptuous habiliments of war, with armillæ of pure gold on both arms, each weighing sixteen ounces. (W. Malmsb. edit. Francof. 1601, l. ii. p. 77.) The same writer (p. 102), describing the manners and customs of the English in 1066, upon the conqueror's arrival, says their arms were laden with golden bracelets; "*Armillis aureis* brachiis onerati."

Arngrim Ionas, in his work on Iceland, speaking of the pagan rites which were used in the chief temple of southern Iceland, in the isle of Kialarnes, describes an armilla of twenty ounces weight, which was kept upon the altar, and which, being sprinkled with the blood of victims, was touched by those who took any solemn oath. He says it was either of silver, or silver and brass mixed. ('Crymog. Rer. Island.' l. i. p. 63.) He adds, that for this purpose it was worn upon the judge's arm during trials. (*Ibid.* p. 76.)

There is a passage in the Saxon Chronicle, under the year 876, which refers to a ceremony not altogether unlike the practice in Iceland. It says, that when the Danes made their peace with the English Alfred, at Wareham in Wessex, they gave him the noblest among them as hostages, and swore oaths to him upon the holy bracelet.

Armillæ, as we learn from Bartholinus, were sometimes marriage presents. Virgins, it appears, did not usually wear them. ('De Armill. Vet.' p. 79.) From different passages in the Roman classics, we learn that they were sometimes given as birth-day presents. Placed among treasures, there was a superstition that an armilla would augment them. Lovers thought them efficacious; and ivory armillæ were used in the cure of epilepsy. See other superstitions in Pliny. ('Hist. Nat.' ed. Harduini, tom. ii. 451, 11; 472, 10; 531, 22.)

Among the articles which from time to time have been turned up in the bogs of Ireland, armillæ of gold have not been the least numerous. Some years ago a very large bracelet of gold was found in Cheshire; and several in the same metal, of different sizes, have been found under Beachy Head in Sussex, amongst the chalk which the tide had undermined. Two or three of these are still preserved in Mr. Payne Knight's collection of bronzes.

The Hamilton, Townley, and Knight collections of antiquities, in the

British Museum, contain armillæ in great quantities, and of almost every variety of form, in gold, in silver, and in bronze. See the Hamilton Room, Case 68; Mr. Knight's collection, Case 8; and the Hamilton and other gems.

In vol. xii. of the 'Archæologia,' pl. li., a bronze armilla is engraved, found upon the wrist of a full-sized skeleton at Westwang Field in the East Riding of Yorkshire. See in the same work (vol. xxii. p. 285) some observations upon an ancient bracelet of bronze, found on the sand-hills of Altyre on the coast of Murrayshire; and also vol. xxvii. p. 400.

In the 'Journal' of the British Archæological Association, vol. ii., are accounts of bracelets in bronze and mixed metal found at Castlethorpe in Buckinghamshire, and at Colchester, Essex; and in subsequent proceedings of the Archæological Association and Institute, will be found other notices of similar discoveries in various parts of the country. In the National Museum at Copenhagen, are some bronze armlets found in Denmark, which appear to have been intended to cover the whole arm, and which M. Worsaae ('Antiquities of Denmark,' trans. by Thoms, p. 34) says belong exclusively to the bronze period. He suggests that they were intended as a protection to the arm against the blow of a sword.

ARMILLARY SPHERE. The Latin word *armilla* signifies a bracelet, and the armillary sphere is one in which the principal circles of the heavens are constructed of some solid material, and put together into their relative positions; thus presenting the appearance of a hollow sphere, of which all the surface has been cut away except the equator, ecliptic, colures, &c. This instrument is now little more than a toy, the complete sphere being generally preferred for the purposes of instruction; but in the ancient astronomy, and even so late as the time of Tycho Brahé, an instrument, the simple description of which is, that it was the whole or part of an armillary sphere, was extensively used in astronomical observation. On this point we refer the reader to ASTROLABE.

ARMINIANS are the followers of James Arminius, or those who are considered to entertain his sentiments. A full account of his doctrines will be found in the notice of ARMINIUS in the BIOGRAPHICAL DIVISION.

ARMOUR is a term generally applicable to any defensive habit, used to protect the person of the wearer from the attack of an enemy. The English word for it in the aggregate, in the fifteenth and sixteenth centuries, was *harness*.

Among the more civilised ancient nations, brass, iron, and other metals, were preferred for its fabrication; and in the time of Asiatic magnificence, even gold was not spared. Herodotus (vii. 71) says that the Libyans who assisted Xerxes in the great army wore leather armour, or probably skins only is meant; of which material, he adds (b. i. 71), the armour of the ancient Persians also was composed.

But for the earliest memorials of armour we must look to the sacred writings, where we find the shield, the helmet, and the breast-plate used by the Israelites. Goliath of Gath (1 Sam. xvii. 6) wore greaves to defend the legs, which were also worn by the warriors of other Asiatic nations; and, at the siege of Troy, by the Grecians in general. Homer's epithet of ἐϋκνημῖδες Ἀχαιοί (the well-greaved Achæi) is familiar to every classical reader. His description of the thorax or breast-plate of Agamemnon, at the beginning of the eleventh book of the 'Iliad,' shows that decorated armour was used at this early period. The same conclusion follows as a matter of course from the description of the shield of Achilles, and it proves that occasionally great pains and skill were employed in decorating armour. The golden armour of Glaucus ('Iliad,' vi. 236) is stated to be worth a hundred oxen. Among the Egyptians, armour of metal was confined to kings and nobles; the helmet of Psammetichus was of brass; the common soldiery wore quilted linen for helmets, and carried large wooden shields. (Xenophon, 'Anab.' i. 8.) The breast-plate which Amasis sent to Athenæa (Minerva) at Lindos was made of linen, on which figures of animals were woven; the ornamental parts were of cotton-thread and gold. (Herod. iii. 47.) As to Greek armour, several specimens of the helmet and cuirass occur upon the frieze of the Elgin marbles; in one instance (slab 51) we have a scaled cuirass richly ornamented. In the bronzes of Siris, purchased from M. Bröndsted for the British Museum, the warriors have helmets and shields only. One has a round, the other an oval shield: their bodies are unclothed. [ALEXANDER, in BIOGRAPHICAL DIVISION, where a representation is given.]

The complete Roman armour consisted of the helmet, shield, lorica, and greaves. The lorica was originally of leather, as we learn from Varro; in the time of Servius Tullius, according to Livy, the whole of the Roman body armour was of brass. The laminated lorica was heavy. Tacitus ('Hist.' lib i.) informs us that its weight was made a subject of complaint by some of the soldiers in the time of Galba; and the emperor himself, in his old age, found the weight of his cuirass too much for his feeble frame. ('Hist.' lib. i. c. 35.) The Roman lorica was frequently enriched on the abdomen with embossed figures, on the breast with a Gorgon's head by way of amulet, on the shoulder-plates with scrolls of thunderbolts, and on the leather border which covered the tops of the lambrequins (or pendent flaps) with lions' heads; and these were formed of the precious metals. Each Roman legion had its own device marked upon its shields. In the time of Trajan, as is exemplified in the armour represented upon his column, the lorica was shortened, being cut straight round above the hips. A bronze breast and back plate of this kind are preserved in the British Museum, upon the front of the former of which one of the paps of the breast still remains, like a high button, to which the shoulder-plates were fastened, which held the back and breast together.

From these facts a general notion will be gathered of the kind of body-armour used among the ancient nations. But as to the minute varieties of it, which are to be found in statues, or upon gems, coins, vases, and other representations, exhibiting the differences and peculiarities which existed, according to the time, the country, or the progress of improvement among the people, the details would be endless. Some of the most important facts will be mentioned under the proper heads, such as SHIELD, HELMET, &c.

Upon the history of defensive armour, as it was worn in England, we shall be more minute. The early Britons are believed to have used none except the shield. Sir Samuel Meyrick, on the authority of Aneurin, the British bard, says, that the Anglo-Saxons under Hengist and others, wore many of them loricæ of leather and four-cornered helmets. This armour, he thinks, was probably acquired through the alliance of their fathers with the Romans, under Carausius and his successors. Aneurin says that Hengist wore scale-armour. A very early illuminated manuscript in the Harleian Collection, No. 603, represents a warrior exactly answering this description. Drawings of the 8th century represent the Anglo-Saxon soldier without any other defensive armour than the shield and helmet, which latter, Sir Samuel Meyrick remarks, seems, in general, to have been nothing more than leather, and is often omitted even in representations of battles. His offensive arms are the sword and the spear. The form of the shield at this period is always oval; it is usually surrounded by a broad rim on the outside, and has a sharp boss projecting from the middle, both of metal; the materials were wood, covered with leather. One of the laws of Æthelstan prohibits the making of shields of sheep's-skin, under the penalty of 30s. The helmet, as it is commonly represented in drawings of this æra, appears to have been either a cap of leather, with the fur turned outwards, sometimes strengthened by a metal rim, or of felt, the *fellen hæt* being often mentioned by Saxon writers, but personages of rank had one of a conical form made of metal and gilt.

When the tunic supplanted the lorica, Sir Samuel Meyrick observes, the Roman pectoral was still retained, and called halſ-beaꞃh or beoꞃᵹ, "neck-guard;" bꞃeoꞅꞇ-beðen, "defence for the breast;" and bꞃeoꞅꞇ-ꞃocc, "breast-plate." It may be seen on a warrior in an illumination in a manuscript of the Cottonian Library, marked Tiberius, B. v., in which the resemblance to the Roman pectoral is quite manifest. The Saxon authors, he continues ('Crit. Inquiry into Ant. Armour.' Introd. p. lxiii.), are by no means explicit with respect to the form or materials of the breast-guards, but the epithet applied to such as were of metal is "rigid." Others are mentioned which are said to have been "rough or shaggy," so that we may suppose them to have been formed of wool or hair, or perhaps of undressed hides.

Notwithstanding these remarks, the word lorica frequently occurs in the writings of the most eminent Saxon authors, and sometimes is mentioned in terms which might imply that it was made of metal. Aldhelm, who lived in the latter part of the 7th century, in some ænigmatical lines ('Poet. nonnulla,' 12mo. Mogunt. 1601, p. 51, 'De Lorica,'), speaks of a warrior's vesture which feared not darts drawn from the long quivers:—

> "—— En! vestis vulgi sermone vocabor:
> Spicula non vereor longis exempta pharetris."

Whether this was the scaled-armour, such as worn by Hengist, or that made of flat rings in the Phrygian style (as designated in Hope's 'Costume'), is not quite clear. In an illumination, however, of the 8th century, a king habited in a tunic covered with flat rings occurs; and in another manuscript of that period similar armour occurs. (See the Cottonian MSS., Claud. B. iv., and Cleopatra, C. viii.) The Saxon authors call this ᵹiehꞃynᵹeð byꞃn, or "ringed byrne." Some illuminations seem to show that the rings were worn edgewise (compare the MS. Cleopatra, C. viii.), and in either case the name is equally applicable. Poems of the 10th century mention the "shining iron rings," but it is probable that it was not in general use till the invasions of the heavier-armed Danes compelled its adoption.

Towards the close of the 9th century, the corium, or corietum, was the armour generally used, and appears frequently in the drawings of that period. It was formed of hides cut into the resemblance of leaves, and covering one another; sometimes all of one colour, as blue, &c., and sometimes of two, as brown and orange; the upper part being of the one, while that which covers the thighs is of the other. It should be observed, that the Saxon byꞃne, originally in shape like a tunic, became in form afterwards a complete cuirass, sitting close to the body, and generally terminating with it. Alcuin ('De Offic. Divin.') speaks of the Anglo-Saxon military tunics of linen in the following terms: "The soldiers are accustomed to wear linen tunics, so well fitted to their limbs as to enable them, with the utmost expedition, to direct the dart, poise the shield, wield the sword," &c. The weight of the ringed byrne seems to have been found a great impediment to activity. Hence, when Harold, in 1063, obtained immediate and decisive success over the Welsh, it was owing to the change of armour among his soldiers. He had observed that these mountaineers could not be pursued to their fastnesses by his troops when clad in ringed tunics, and he therefore commanded them to use their ancient leather suits, which would not impede their activity. (Ingulfus, fol. 68. Joh. Sarisb. 'De Nugis Curialium,' lib. vi. c. vi. p. 185.)

The Saxon artists, it appears, made no distinction between the cynehealm, or royal helmet, and the crown. The monarch is depicted by them, in his court and in the field of battle, with the same kind of head-covering, even when every other part of his dress is marked with decisive variation; but upon the figure of Edward the Confessor, in his great seal, the diadem is evidently put on a helmet. The casque of the nobility is usually pointed in the form of a cone, and made of brass or some other metal. In the two succeeding centuries its shape is the same; but it is ornamented with gold and precious stones, and is improved by the addition of a small piece to protect the nose, called a nasal. (See an illumination in the Cottonian MS., Tiberius, B. v.)

Leg-guards are decidedly mentioned by the early Saxon writers; but they uniformly appear to have been made of twisted pieces of woollen cloth, coming from within the shoe, and wound round the legs to the top of the calves, in imitation of the hay-bands used by their rude ancestors.

The shield still continued oval, and indeed until the Norman conquest; but it differed from time to time greatly in dimensions, especially in the 10th and 11th centuries, in the drawings of which times it appears of various sizes, from a magnitude sufficient to cover the head and body, to a diameter not greater than a foot and a half. This variation is further supported by historical testimony, for we find mention made of "little shields," and "smaller shields." In the will of Æthelstan, dated 1015, the shoulder-shield is included among the legacies, and it is distinguished from the target. It was probably of the larger sort, and received its appellation from being usually slung upon the shoulder.

When the Danes made their first appearance in England, Sir Samuel Meyrick says, they seem to have had no other armour than a broad collar which encircled their chest and the lower part of their neck, or a small thorax of flat rings, with greaves, or rather shin-pieces, of stout leather. About Canute's time, the Anglo-Danes adopted a new species of armour, which, he thinks, they probably derived from their kinsmen, the Normans. This consisted of a tunic, with a hood for the head and long sleeves, and what were afterwards called chausses, that is, pantaloons, covering also the feet, all of which were coated with perforated lozenges of steel, called, from their resemblance to the meshes of a net, macles, or mascles. They wore, too, a helmet, or skullcap, in the shape of a curvilinear cone, having on its apex a round knob, under which were painted the rays of a star. This helmet had a large broad nasal to protect the nose, and the hood was drawn up over the mouth, and attached to it, so that the only exposed parts were the eyes. The authority for these observations is the manuscript in the British Museum commonly called Canute's Prayer-book. Spears, swords, and battle-axes, or bipennes, were the offensive arms. The shields were either circular or lunated; a law of Hacon, who died in 963, directs that the shield should be of two boards in thickness, and painted red.

Such had been the state of armour in Britain when William led his army of Normans and Flemings to the victory at Hastings.

From this period, the great seals of our kings, those of the greater barons, and monumental effigies, give the outline of the changes which took place in the fashions of armour. The great seal of William the Conqueror represents him on one side seated on a throne, upon the other he is in a hauberk apparently of rings set edgewise, which kind of armour had been used by the Anglo-Saxons. The Norman body-armour represented in the Bayeux tapestry is of two kinds; one of rings or mascles, sewn flat on the vesture; the other of leather. The helmets are conical, and have the nasal. The ring-armour of the Bayeux tapestry is a tunic descending below the knee, but divided before and behind for the convenience of riding, so that the sides hang down so as to resemble short trousers: "This," says Sir Samuel Meyrick, "I take to be the haubergeon, as there are some few specimens of the tunic or hauberk, and both being mentioned in the 'Roman de Rou.' This opinion," he adds, "is further strengthened by a specimen of this curiously shaped armour existing on a monument in Ireland as late as the time of Edward III. It appears to have been put on by first drawing it on the thighs, where it sits wide, and then putting the arms into the sleeves, which hang loosely, reaching not much below the elbow, as was the case with the Saxon flat-ringed tunic: the hood (Mr. Planché prefers the term cowl, in order to distinguish the capuchon or cowl from the hood or chaperon) attached to it was then brought up over the head, and the opening on the chest covered by a square piece, through which were passed straps, that fastened behind, hanging down with tasselled terminations, as did also the strap which drew the hood, or capuchon, as it was called, tight round the forehead. This is evident in several figures in the Bayeux tapestry; but the manner in which the armour was put on and fastened is best shown where William is arming Harold. The Duke of Normandy is there represented as placing the helmet on the head of the Saxon earl with his left hand, while his right is busied making tight a strap, which is drawn through the rings on the breast of the latter. No examples of such shaped armour in England occur previously or in any subsequent reign; but it appears to have been introduced into Ireland, and worn in that country, as has been above observed, as late as the time of Edward III.; nor does any distinguishing name seem to have been applied to it: hence I conclude that it is what Wace calls the haubergeon, in his description of the appearance at the battle of Hastings of Bishop Odo, the conqueror's half-brother." The legs of the figures in the tapestry are, generally speaking, bound with bands of different colours, rising out of the shoe in the ancient Saxon manner; but in some instances, and where the hauberk is worn, they appear covered with mail to the ankles. Such, however, is the case only with the most distinguished characters, as William, Odo, Eustace, &c. This covering for the legs, according to William of Malmesbury, was called *heuse* or *hose;* whence Robert of Normandy being rather short-legged, we are told by Ordericus Vitalis, his contemporary, was often called by his father Curt-hose. The shield, as depicted in the tapestry, and introduced by the Normans, was of a very peculiar form. It has been called heater-shield and kite-shield by modern antiquaries, from its supposed resemblance to those familiar objects; but by the Normans themselves it was merely termed *escu*, from the Latin, *scutum*. While in the tapestry most of the Saxon shields are represented round or oval, with a central boss, as in the illuminations of that people, there is no instance of a Norman with any other than the long kite-shaped shield. These shields were hung on the arm by an inner strap, which left the hand free, and gave them a great advantage over the Saxons by whom the shield was grasped by the hand and held straight forward; so that to wield the heavy double-handed battle-axe, they were forced to relinquish the shield.

The armour of the reign of William Rufus remained precisely the same as in that of the Conqueror; and we have no new specimen of any part, except the *chapelle de fer*. This appears on the seal of Rufus, and resembles a Tartar cap, being a cone which projects beyond the head.

The great seal of Henry I. represents that king in flat-ringed armour. Other specimens of his time occur in the enamelled copper of Geoffrey Plantagenet, engraved by Stothard, and described by John of Marmoustier, and in a representation of similar date, engraved by Strutt, in his 'Dresses and Habits of the People of England,' from a manuscript in the possession of the late Francis Douce, Esq.

In the reign of Stephen, what is called tegulated armour appears to have prevailed, which consisted of several little plates, covering each other in the manner of tiles, and sown upon a hauberk, without sleeves or hood. The seal of Richard Fitzhugh, Earl of Chester, engraved in the 'Vetusta Monumenta,' of the Society of Antiquaries, affords a fine specimen of this kind of hauberk. The nasal of the helmet appears to have been disused toward the close of this reign; though, upon his great seal, Stephen is represented with it.

Henry II. is represented upon his great seal in a flat-ringed hauberk, wearing a conical helmet without a nasal. The flat rings, however, gave way soon after the commencement of his reign, and the hauberk with rings set edgewise came into general fashion. The shape of the shield became somewhat shortened, and often more angular on each side at the top.

Richard I., in his first seal, appears in a hauberk of rings set edgewise, from under which falls the drapery of his tunic; in the second seal he has the same without drapery; in both he is represented with chausses; in the first, wearing a conical helmet, but with its apex somewhat rounded; in the second with a cylindrical one, surmounted by the *planta-genista* (or broom-plant) in reference to his name, and having an aventaille or plate to protect the face.

The great seal of John affords the first example of an English king wearing a surcoat; it is put over a hauberk of rings set edgewise. Surcoats are supposed to have originated with the crusaders, for the purpose of distinguishing the many different nations serving under the banner of the cross, and to throw a veil over the iron armour, so apt to heat excessively when exposed to the direct rays of the sun. Besides the surcoat the haqueton and the gambeson were military garments in great esteem during this reign. They were both padded, the latter stuffed with wool in buckskin, the first in leather, stuffed with cotton. Thus, in a wardrobe account dated in 1212, we find a pound of cotton was expended in stuffing an aketon belonging to King John, which cost twelve pence, and the quilting of the same was charged at twelve pence more. John is represented with a cylindrical helmet, but without any covering over his face. The monument in the Temple church ascribed to Geoffrey de Magnaville, or Mandeville, which appears to be about this period, has one very similar, but with a nasal and cheek-pieces. A helmet of this time, "of a very cumbrous and inelegant form, and which was only worn in actual combat, when it was placed over the coif-de-mailles and chapel-de-fer (*Angl.*, mail hood and iron skull-cap), and rested on the shoulders," was found a few years ago in digging among the ruins of Eynsford Castle, Kent, and is now in the collection of the Earl of Warwick. (Planché.)

Henry III.'s great seals afford us the earliest specimen of the *ouvrages de pourpointerie*, which came more into fashion towards the latter part of his reign. His hauberk and chausses are of this padded work, stitched. On his first seal his helmet is represented as with the visor or aperture for sight, not in the aventaille, but in the helmet itself, while the latter has merely perforations for the breath, and is therefore fixed at the lower part. His second seal exhibits him in a cylindrical helmet of a more perfect form, the aventaille, which contains both the before-mentioned conveniences, being apparently made to open and shut by means of hinges and a clasp. This seal of Henry III. also represents him in a surcoat. A remarkable monumental effigy of a knight in this reign, in the armour of rings set edgewise, occurs in the church of Malvern in Worcestershire. The monumental figure of Richard Longespée, Earl of Salisbury, who died in 1224, is another specimen. "The horse soldiers, at this time," says Sir S. Meyrick, "consisted of the heavy cavalry, who were the knights, and completely covered with mail, or, as Matthew Paris expresses it, *ad unguem armatos*, the face and left hand excepted." In a manuscript, entitled 'The Lives of the Offas,' written by Matthew Paris (MS. Cotton. Nero, D. i.), and of the time of Henry III., the knights appear generally in gamboised armour (padded work, stitched), with surcoats, and wearing shin-pieces or greaves of steel. One, however, is in a hauberk, with hood and chausses of flat contiguous rings, and probably this is the latest example of such armour being worn. Some appear with visors, consisting of a convex plate of steel, on which is a cross, with perforations for the sight, and punctures for the breath, tied upon the hood. Others have a nasal skullcap, though not the latest representation of this defence; and others the cylindrical helmet common to this period. The helmets of the kings are distinguished from the rest by a crown at top. They have all, too, those coverings for the knees called poleyns. This word is often erroneously confounded with poulaines, which were the long points at the toes of shoes, worn in Richard II.'s time, as well as anterior; but we learn from the following passage from Carolus Blessensis, in Lobineau's 'Hist. Bretagne,' vol. ii. p. 566, that they were for the knees: "Fecit sibi per Oliverium auferri à genibus polenas, et antebrachia à brachiis:" He caused Oliver to take the poleyns from his knees, and the vambraces from his arms. Pourpointing, or elaborate stitching, it appears, became at this time a trade, and there were several pourpointers in Paris and London. The use of the pourpoint seems greatly to have gained ground, and the military in the delineations of this and the next reign are almost constantly depicted in it. Sir Samuel Meyrick says, "it has been observed, that in the illuminations of this period, the archers are represented wearing leathern vests over their hauberks of edge-ringed mail. These appear to have been the jack in its primary form, which originated with the English, and which afterwards assumed a shape so cumbersome. From the 'Chronicle' of Bertrand du Gueschin, composed about the time of Richard II., we learn that it continued to be worn over the hauberk, for he says, "S'avoit chascun un jacque par dessus son haubert,'—each had a jack above his hauberk. The small vest was called jacket, and in the Latin of the time *jaquetanus*, as was the *jacque*, *jacquemardus* and *jacobus*. The monument of Eudo de Arsic, who died about the latter part of this reign, seems to represent him in the jacque. He is clad in mail, and wears this garment, which is made with sleeves, sits close to the body, is buttoned down the front, and has a puckered skirt reaching to the knees. In later times it was generally of leather, for Coquillart, an old French writer, 'sur les Droits nouveaux,' describes it as of chamois, extending to the knees, and stuffed with flocks, so as to be a kind of pourpoint. During the latter part of this reign, the shape of the helmet underwent a partial change, taking the form of a truncated cone on the top of a cylinder: the apertures for the sight were horizontal, and pierced in the transverse part of a cross that ornamented the front, covering the whole head and resting on the shoulders. The crusade in this reign, says Sir Samuel Meyrick, seems to have introduced a new and most ingenious species of armour, probably of Asiatic discovery, and still worn by those nations at the present day. This was the interlaced rings, which, as dependent on each other, did not require to be sewn to an under garment. The earliest specimen he considers to be the monumental effigy of De l'Isle, in Rampton church, Cambridgeshire, which exhibits him in the flat coif worn during the greater part of this reign, but made, as well as his hauberk and chausses, of interlaced chain. The shape of his shield, however, is that of the close of Henry III.'s reign, and, with his surcoat, is ornamented with his armorial bearings. The shields, however, had generally become flatter, the top was straight, and the custom of emblazoning them was coming rapidly into use. The *chapelle de fer* continued to be used in this reign. The chanfron, or armour for the horse's head and face, first occurs in the clause-roll of the fifty-fourth Henry III.

Considerable improvements were made in armour during the reigns of the first three Edwards. Ailettes, or shoulder-pieces, appear to have been introduced in that of Edward I. In Edward II.'s time, armour appears to have assumed a mixed character, being neither altogether mail nor wholly plate. *Armures de fer*, towards the close of this reign, became the distinctive term, among the French writers, for plate-armour. The Florentine annals, says Sir Samuel Meyrick, consider the year 1315 as remarkable for a new regulation in armour, by which every horseman who went to battle was to have his helmet, breastplate, gauntlets, cuisses, and jambes all of iron, a precaution which was taken on account of the disadvantages their cavalry had suffered from wearing light armour at the battle of Catino; but this usage did not find its way into general practice in Europe for at least ten years after. The seal of Edward Prince of Wales, afterwards King Edward III., represents him with ailettes on which are his arms, in the same manner as Edmund Crouchback is exhibited in Westminster Abbey, and in a missal belonging to the late Francis Douce, Esq. What is curious in this is the early representation of the mamelieres, or pieces put on the breast, from which depended chains, one of which was attached to the sword-hilt, and the other to the scabbard. The armour at the close of this reign may be seen in an initial letter of a grant from King Edward II., constituting his brother, Thomas de Brotherton, Marshal of England. (See the MS. in the Cottonian Library, Nero, D. vi.) In the chancel of Ash church, in Kent, is the monumental effigy of a knight which exhibits still further the progress toward plate-armour. The helmet was still conical and frequently surmounted by a crest. The shield had become triangular or pear-shaped.

The helmet on the seal of Edward II. is of a cylindrical form, with a grated or pierced aventaille and visor attached: a clasp which fastens this on the right side is very visible, and it is probable that on the other it was retained by hinges. It was very much the custom during this reign to wear over the armour the cointisse, or surcoat, ornamented with the warrior's arms: this was sometimes shorter before than behind, as is shown in a brass in Minter church in the Isle of Sheppey.

The monumental effigy of John of Eltham, who died in 1329, exhibits the fashion in which armour was worn at the commencement of the reign of Edward III.; similar to which is the figure on the monument of a knight in Ifield church, in Sussex. The splendid manner, it is observed, in which some of the knights of this period chose to have their armour made proved sometimes fatal to them. Froissart tells us, that "Raymond, nephew to Pope Clement, was taken prisoner, but was afterwards put to death for his beautiful armour." The monument of Sir Oliver Ingham, at Ingham church, in Norfolk, who died in 1343, shows the further gradual progress of mixed armour. His monument also affords us one of the earliest specimens of the justing helmet of this time, surmounted by its crest—an owl with wings expanded. The equestrian statue of Bernabo Visconti, at Milan, engraved in the 'Archæologia,' vol. xviii. pl. xii. xiii. xiv. with its details, affords a magnificent specimen of the mixed armour used at this time upon the continent. Moveable visors attached to the bacinets (or skull-caps in the form of a bason) appear to have come in about the middle of the reign of Edward III. The Black Prince's monument at Canterbury, who died in 1360, is another specimen of the period. The monument of Humphrey de Bohun, Earl of Hereford, in 1367, Sir Samuel Meyrick observes, is the earliest specimen of plate-armour with taces, or overlapping plates to envelope the abdomen, at the bottom of the breastplate, without any surcoat. It was not till the reign of Henry V. that this practice became general. The surcoat about this time began to give place to the jupon, which was richly ornamented with heraldic bearings. Humphrey de Bohun wears plate over the insteps, but the rest of his feet is covered with chain. The leathern gauntlets were furnished at the knuckles with knobs or spikes of iron, called *gadlings*, which were often used to good purpose on an adversary, and seem to be the precursor of the barbarous modern American *knuckle-duster*. The gauntlets of Edward the Black Prince, thus armed, are hung above his tomb in Canterbury Cathedral.

The reigns of Richard II. and Henry IV. were still more distinguished by the increased ornament of armour. The armourers of Italy were much employed at this time by the English nobility. When Henry, Earl of Derby, proposed to combat with the Duke of Norfolk at Coventry, he sent to Galeazzo, Duke of Milan, for armour, who gave the knight who bore Henry's message not only the choice of all his armour, but sent with him to England four of the best armourers of Milan to give personal attendance upon Henry for his equipment. Chaucer, noticing a tournament at this period, says,

> "Ther mayst thou see devising of harneis
> So uncouth and so riche, and wrought so well
> Of goldsmithry, of browdying, and of stele;
> The sheldes brighte, testeres, and trappures;
> Gold-beten helmes, hauberkes, and cote-armures."—v. 2498.

Soon after the year 1400, chain-mail seems to have been entirely disused; and the complete armour of plate adopted. Henry V. is so represented on his great seal, as well as in one of the illuminations of the celebrated Bedford Missal; in the latter he is represented being armed by one of his esquires. Black armour was at this period often used for mourning. Henry IV. is constantly represented in black armour in the illuminations to the celebrated manuscript on 'The Deposition of Richard II.,' preserved in the Harleian Collection. The vizor of the basionet assumed fanciful shapes, and was sometimes formed so as to resemble the beak of a bird. In the time of Richard II., and under Henry V. the panache or plume of feathers was placed upon the helmet as an ornament.

A more splendid specimen of armour of the reign of Henry VI., than that represented on the effigy of Richard Beauchamp, Earl of Warwick, in the Beauchamp Chapel at Warwick, will not be found anywhere; he died in 1439. Armour was becoming lighter by degrees. The jazerine, a jacket composed of small overlapping plates of iron covered with velvet, frequently supplied the place of the breast and back-plates.

The fashion of armour prevalent through the reign of Edward IV. may be judged of from that monarch's great seal, and from the monumental effigy of Sir John Crosby, in the church of St. Helen, without

Bishopsgate, in London. The latter died in 1475. Soon after this time, numerous specimens of armour occur with immense elbow-plates; these continued till the time of Henry VIII.

The perfection of plate armour is supposed to have been attained in the reign of Richard III. The effigy of Sir Thomas Peyton, in Isleham church, Cambridgeshire, furnishes an excellent specimen. The head was defended by the casque, and the shield had become nearly pentangular.

Fluted armour was sometimes used in the reign of Henry VII.; this fashion is supposed to have come from Germany. The helmet assumes the form of the head, but presents a salient angle in front. The breast-plate is globular; and *lambays*, or steel plates to protect the thighs when on horseback, have been adopted.

Drawings of various military figures of the middle of King Henry VIII.'s reign, made at the time, occur in the Cottonian manuscript in the British Museum marked Augustus II., and amongst them Henry himself in armour. A great deal of the armour of this period had devices, arms, &c. stamped or engraved upon it; and some was *damasquinée*, or inlayed with gold. The alterations were chiefly those of ornament.

In the reign of Edward VI. a slight change took place in the form of the breast-plate, which was again a little changed in the reign of Mary. During Elizabeth's reign, no great alteration took place. "But armour *cap-à-pie*," says Sir Samuel Meyrick, "began to fall into disrepute soon after the accession of King James I., and in the latter part of his reign, the jambs or steel coverings for the legs were almost wholly laid aside."

King Charles I. is continually represented in armour; and he took great pains to bring about a uniformity in the fashion of armour among his officers and soldiers. But the troubles of his reign, and the success of the levellers of that period, caused a material alteration, so that soon after the establishment of the Protectorate we find the helmet and cuirass only worn; the latter consisting of a breast and back plate. The wearing of armour to the knees continued only to the time of Cromwell. The cuirass and a kind of helmet, however, are still retained amongst us for the royal regiments of Life Guards; and have, likewise, been resumed in the armies both of the French and Germans.

The reader who wishes for further information may consult Sir Samuel Meyrick's 'Engraved Illustrations of Ancient Armour from the Collection at Goodrich Court,' 2 vols. fol. Oxford, 1830, where (pl. iv. to x.) a series of tournament armour of successive dates, from 1458 to 1586, is exhibited.

Bordeaux steel is frequently mentioned by Froissart as excellent for armour. Felippo Negroli, of Milan, was the eminent armourer who worked for Francis I. of France, and the Emperor Charles V.

Some remarks on the ancient mode of putting on armour, communicated to the Society of Antiquaries by Sir Samuel Meyrick in 1821 (Archæologia,' vol. xx.), unravel, by the help of an ancient document, what was previously an enigma. The knight began with his feet and clothed upwards, namely; 1, his sabatynes, or steel clogs; 2, the greaves, or shin-pieces; 3, the cuisses, or thigh-pieces; 4, the breech of mail; 5, the tuillettes, or overlapping pieces below the waist; 6, the breast-plate, or cuirass; 7, the vambraces, or covers for the arms; 8, the rere-braces, or arrière-bras, the covering for the remaining part of the arm to the shoulder; 9, the gauntlets; 10, then the dagger was hung; 11, the short sword; 12, the cloak or coat, which was worn over the armour; 13, the bacinet; 14, the long sword; 15, the pennoncel, held in the left hand; 16, the shield.

For this account of armour, various works have been consulted—Grose's 'Treatise;' Gough's 'Sepulchral Monuments,' &c; but the chief outline has been taken from Sir Samuel Meyrick's 'Critical Inquiry into Ancient Armour as it existed in Europe, but particularly in England, from the Norman Conquest to the Reign of Charles II.' The collection of ancient armour possessed by that gentleman's son at Goodrich Court, in Herefordshire, and his own extensive researches, have supplied more information upon the subject than it is probable could have been given by any other writer.

(Planché's *History of British Costume.*)

ARMS, from the Latin *arma*, in a general sense, includes all kinds of weapons, whether of offence or defence, about the earliest of which we have any mention being the bow and arrow. Isaac told Esau to take his quiver and his bow and go out to the field and take some venison (about 1760 B.C.). It enabled man to kill wild animals for food before its use was required as a weapon of war. As a military weapon, it was probably succeeded by the sling. Lucretius says,—

"Arma antiqua, manus, ungues, dentesque fuere," &c.

* * * * * *

Man's earliest arms were fingers, teeth, and nails,
And stones, and fragments from the branching woods,
Then fires and flames they joined, detected soon;
Then copper next; and last, as latest traced,
The tyrant iron, than the copper vein
Less freely found, and sturdier to subdue.

Homer and Hesiod tell us, that in the early ages, the arms and instruments of the heroes were composed entirely of χαλκός (*copper*), perhaps hardened with tin. The word is commonly translated *brass*, but is more properly speaking bronze. Defensive arms have been already treated of under ARMOUR. The present article is confined chiefly to weapons of offence.

The Jews appear to have had swords, daggers, spears, javelins, bows, arrows, and slings: axes or maces were also used by them as weapons of war. According to Josephus, the use of iron arms was first taught by Joseph, who armed the troops of Pharaoh with casque and buckler.

Herodotus (vii. 61-80) gives a minute description of the weapons used by most of the different nations which formed the great army of Xerxes. Amongst these, the Medes and Persians had short spears, bows, arrows made of reeds, and daggers; the Assyrians, besides spears and daggers, had wooden clubs knotted with iron; the Bactrians and Parthians, bows made of reeds, and short spears; the Arabians had bows, large, flexible, and curved at the ends; the Æthiopians, bows made from the spathe (σπαθη) of the palm, four cubits, or six feet, long; their arrows were short, and pointed with sharp stones instead of iron; they had spears headed with the sharpened horns of the *dorcas* [ANTELOPE, in NATURAL HISTORY DIVISION], and knotted clubs. The Libyans had their spears hardened at the end by fire. The Paphlagonians, Phrygians, and Thracians, had spears, javelins, and daggers. In the Persian army at the battle of Cunaxa, we find chariots armed with scythes mentioned. (Xenophon, 'Anab.' i. 8.)

The Grecian armies were composed of various sorts of soldiery. In the earliest ages, as we see from Homer, the chief personages often fought in chariots; but this practice seems not to have existed in the historical ages. The cavalry of Thessaly and that of Macedonia obtained the highest reputation among the Greeks. It was with this cavalry that Alexander mainly defeated both the troops of the Persian king and those of the rulers of the Punj-ab. With the age of Alexander elephants were brought into use, and they were employed both by Pyrrhus the Greek King of Epirus, and by Hannibal, in their invasions of Italy. The Greek foot soldiers were distinguished by the terms ὁπλῖται (*hoplitai*), those who wore armour, and carried broad shields and long spears; and ψιλοί (*psiloi*), the light troops, who, with no other protection than a helmet, were armed with darts, bows and arrows, or slings. The πέλτασται (*peltastai*), who carried the peltæ, or narrow-pointed shields, and spears, were a species of light troops, and considered as an intermediate kind. The heavy-armed foot were the chief strength of the Grecian armies.

The Greek spears were generally of ash, with a leaf-shaped head of metal, and furnished with a pointed ferule at the butt, with which they were stuck into the ground. Pausanias saw a spear in the temple of Minerva at Phaselis, said, according to the legend, to have belonged to Achilles, the blade and ferule of which were of copper. The same diligent and credulous observer saw a knife at Nicomedia, made wholly of copper, reputed to have once belonged to Memnon. The Macedonians had a particularly long spear called σάρισσα (*sarissa*), which was fourteen or sixteen cubits in length. (See Polybius for this extraordinary length, and the notes to the 'Onomasticon' of Julius Pollux, v. σάρισσα.)

Swords, spears, javelins, bows, and slings, were the offensive arms of the Romans, whose infantry soldiers were divided into *hastati*, who fought with spears; *principes*, who led the van; *triarii*, the third line; *velites*, the light troops; *funditores*, the slingers; and *sagittarii*, the archers. Their cavalry used the javelin on horseback. The arrows of the saggittarii had not only their pikes barbed, but were furnished with little hooks just above, which easily entered the flesh, but tore it when an attempt was made to draw them out. What greatly contributed to render the Romans masters of the world, was, that as they successively fought against all nations, they renounced their own arms and methods of fighting, introducing any improvements they met with. Romulus, after the war with the Sabines, is said by Plutarch (Romulus, 21) to have adopted the broad buckler of that nation, instead of the Argolic buckler (*aspis Argolica*), which the Romans had used till that time: a story of little historical value, but confirmatory of the opinion that the Romans improved their military art by adopting the best things from other nations, and that they traced this policy to the supposed origin of their national existence.

The early Saxons, previous to their arrival in Britain, besides the buckler and dagger, used a sword bent forwards like a scythe; but their descendants soon changed it for one that was long, broad, straight, double-edged and pointed. The ordinary weapons of the Saxons, after their arrival in our island, for the infantry, were spears, axes, bows and arrows, clubs, and swords. Few of the infantry had any other defensive armour than small round shields with spikes in the centre. The cavalry were more uniformly armed with long spears which they carried in their right hands, and swords which hung by a belt on their left sides.

The arms of the Normans differed but little from those of the Saxons; their spears or lances were usually made of some light strong wood, with a well-tempered steel point: to these, with the sword and dirk, they added the cross-bow, as has been already shown in the article ARCHERY. The Normans also appear to have introduced a kind of field-artillery, consisting of machines from which darts and stones were thrown to a considerable distance: some of the arrows were also headed with combustible matter for firing towns and shipping.

Our military weapons were probably but little altered till the time of Edward I. when the English long-bow seems to have been adopted, or rather perfected and confined to the use of infantry.

Gunpowder was invented in the 13th, and the larger sort of fire-arms in the 14th century: these will be separately treated of under the head of ARTILLERY.

Portable or hand fire-arms, to which we shall confine ourselves at present, were not invented till a century later. Sir Samuel Meyrick in a Memoir in the 'Archæologia' of the Society of Antiquaries, has collected most of the scattered notices to be found in military writers relating to their introduction. He has indeed given the very year of their invention, upon the authority of an eye-witness. "It was in 1430," says Bilius, "that they were contrived by the Lucquese when besieged by the Florentines." Villaret, however, states that John, Duke of Burgundy, had 4000 hand cannons, as they were called, in his army in 1411 (Villaret, t. xiii. p. 176, 310). The French and Italians appear to have made the principal improvements.

A French translation of Quintus Curtius, written in 1468, preserved among the Burney manuscripts in the British Museum, exhibits two warriors in one of its illuminations, who bear the earliest representations of hand fire-arms with which we are acquainted: they appear to be hand-guns.

The following is the enumeration of the different pieces of portable fire-arms and their accompaniments, almost all of which have been engraved by Skelton, in his 'Specimens of Arms and Armour.' Hand-cannon, hand-gun, arquebus, arquebus à croc, haquebut, demi-haque, musket, wheel-lock, currier, snaphaunce, caliver, carabine, esclopette, fusil, musquetoon, fowling-piece, petronel, blunderbus, dragon, hand-mortar, dag, pistol, tricker-lock, fire-lock, self-loading gun, fancy-gun, musket-arrows, match-box, powder-horn and flask, touch-box, bandeleers, cartridges, patron, sweynes-feathers, and bayonet. The recollection of the fact, that *phialæ* (small pots) had been sometimes used for casting the Greek fire, was likely to lead to some more dexterous invention. The emperor Leo, in his 'Tactics,' ch. xix. § 6, *περὶ ναυμαχίας, on sea fight*, describing the use made of artificial fires in vessels employed in pursuit after a naval battle, says, "on the prows of such vessels were placed *σίφωνες* (*siphones*), large tubes; they were of copper, through which these fires were blown into the enemies' ships." Anna Comnena ('Alex.' l. xiii.) says, "that soldiers were supplied with copper tubes, and blew artificial fire in the same way upon their enemies in battles on land." Here we have, undoubtedly, the origin of fire-arms.

The *hand-cannon* was a simple tube fixed on a straight stock of wood, about three feet in length. It was furnished with touch-hole, trunnions, and cascable, like a large cannon. The touch-hole was, in the first instance, at top; but the liability of the priming to be blown away led to the improvement of placing a small pan under the right side to hold the powder. This pan was the first step to the invention of the gun-lock.

The *hand-gun* was an improvement on the hand-cannon. It was cast in brass, and, as a tube, was of greater length; a flat piece of brass, made to turn upon a pin, covered the pan which contained the powder; it had also the addition of a piece of brass fixed on the breech, and perforated to insure the aim. The hand-gun appears to have been in use in England at least as early as 1446. The Greeks made use of it to great advantage in their last defence of Constantinople in 1453.

As soon as the hand-gun had received a contrivance suggested by the trigger of the cross-bow, to convey with certainty and instantaneous motion the burning match to the pan, it acquired the appellation of *arquebus*, corrupted into harquebus. Previous to this invention, the match had been held in the hand in using the hand-gun as well as the hand-cannon. The arquebus is first mentioned by Philip de Comines, in his Account of the Battle of Morat in 1476. In England, on the first formation of the Yeoman of the Guard in 1485, one-half were armed with bows and arrows, the other with arquebuses. At the battle of Fournoe, in 1495, we read of mounted arquebusiers. A large party of arquebusiers are seen in the picture at Hampton Court which represents King Henry VIII.'s procession to meet Francis I., between Guisnes and Ardres. The arquebus, like the hand-cannon and hand-gun, being fired from the chest, while its butt remained straight, the eye could with difficulty only be brought sufficiently near to the barrel to afford a perfect aim. By giving to the butt a hooked form, the barrel was elevated, while the horizontal position would be retained. This idea, originating with the Germans, gave name to the fire-arms thus constructed, and was thence by the English termed a *haquebut*, hakebut, hagbut, or hagbush. The invention as well as the name was known in England as early as the reign of Richard III. We find numerous haquebutters in the English army in the time of Henry VIII.

The *demihaque* was a kind of long pistol, the butt-end of which was made to curve so as almost to become a semicircle. The demihaques were smaller, and probably about half the weight of the haquebuts, the diameter of the barrel being much less. In the 'Gesta Grayorum,' printed in 1594, we are told they carried bullets, and sometimes half-shots.

The *musquet* is sometimes stated to have been a Spanish invention. We find, however, that that arm was seen for the first time in 1432, in Tuscany. (Muratori, Dissert. 26, p. 457.) And, in 1449, the Milanese are said to have armed their militia with 20,000 muskets, which Sismondi (t. ix. p. 341) states, required a quarter of an hour to load and fire. Hallam, however ('Middle Ages,' vol. i. p. 342), doubts the fact of so many muskets having been collected. It was used at the battle of Pavia, and is said to have contributed in an especial manner to decide the fortune of the day. Its use, however, seems for a while to have been confined. It appears not to have been generally adopted till the Duke of Alba took upon himself the government of the Netherlands, in 1567. M. de Strozzi, Colonel-General of the French infantry under Charles IX., introduced it into France. The first Spanish musquets had straight stocks; the French, curved ones. Their form was that of the haquebut, but so long and heavy, that something of support was required; and hence originated the *rest*, a staff the height of a man's shoulder, with a kind of fork of iron at the top to receive the musquet, and a ferule at bottom to steady it in the ground. On a march, when the piece was shouldered, the rest was at first carried in the right hand, and subsequently hung upon the wrist by means of a loop tied under its head. A similar rest had been first used by the mounted arquebusiers. In the time of Elizabeth, and long after, the English musqueteer was a most encumbered soldier. He had, besides the unwieldy weapon itself, his coarse powder for loading, in a flask; his fine powder for priming, in a touch-box; his bullets in a leathern bag, the strings of which he had to draw to get at them; while in his hand was his burning match and his musquet rest; and when he had discharged his piece, he had to draw his sword in order to defend himself. Hence it became a question for a long time, even among military men, whether the bow did not deserve a preference over the musquet.

An ingenious contrivance to supplant the match-lock appeared in the reign of Henry VIII. This was the *wheel-lock*, invented in Italy. M. de Bellai informs us, that one of the first occasions on which it was used was in 1521, when Pope Leo X. and the Emperor Charles V. confederated against France, and their troops laid siege to Parma, which was defended by the Marquis de Foix. It was a small machine for exciting sparks of fire by the friction of a furrowed wheel of steel against a piece of sulphuret of iron, which, from such application, acquired the name of pyrites or fire-stone. The spring which turned this wheel was attached to it by a chain, formed like those in watches, and was wound upon the axle, or, as the term was, 'spanned' with a small lever called a spanner. This instrument, having at one end a hole made square to fit on the projecting axle of the wheel, was used like a key to wind a clock; and, being turned, made the wheel revolve, and a little slider that covered the pan retire from over it. The spanner was then removed, and the wheel was held by a catch connected with the trigger. The cock, like that in modern firelocks, except having its position reversed, containing the pyrites, was brought down upon the wheel, which, on the trigger being pulled, revolved rapidly, and grating against the pyrites elicited the fire. Wheel-locks were for a long time chiefly manufactured in Germany. They were certainly brought to England in the time of Henry VIII., in whose reign we find them mentioned in inventories under the name of 'fierlocke.' Benvenuto Cellini ('Memoirs,' vol. i. p. 182, Roscoe's transl.) mentions his mounting a brown Turkish horse, and placing a wheel lock arquebus at the pummel of the saddle, in the year 1530.

The *Currier*, or *currier of war*, is another species of fire-arm, first noticed in a letter from Lord Wentworth to Queen Mary (see the 'Hardwick State Papers'), while writing respecting the siege of Calais. It is again noticed in the Earl of Essex's operations in Ireland in the time of Queen Elizabeth. (Birch's 'Memoirs.') The earliest account of it is given in a work entitled 'The Knowledge and Conduct of Warres,' printed in 1578. Sir John Smith, in his 'Animadversions on the Writings of Captain Barwick,' describes it as of the same calibre and strength as the arquebus, but with a longer barrel.

Grose observes, that the *Snaphaunce* derived its name from the troops who made use of it. These were a set of marauders whom the Dutch termed *snaphans*, or 'poultry-stealers.' The use of the match-lock exposed them to this inconvenience, that the light from the burning match pointed out their position, and they were unable to purchase the wheel-lock from its expense. In this dilemma they formed the snaphaunce from a study of the wheel-lock. A flat piece of steel, furrowed in imitation of the wheel, was placed on a steel post, which, being screwed beyond the pan, was made moveable. Then the furrowed piece being brought to stand over it, on pulling the trigger, the flint, which they substituted for the pyrites in the cock, struck against it, and the spark was produced. This was an invention of the time of Elizabeth, and its comparative cheapness rendered it fashionable in France, Holland, and England. The snaphaunce was a near approach to the fire-lock.

The *Caliver* differed from the musquet in being lighter and shorter. It was a fire-arm of a regulated standard as to the diameter of its bore, which was larger than that of the arquebus. It was made to fire with a match-lock. A match-lock caliver is preserved at Brancepeth Castle, Durham, which bears the date of 1611.

Of the *Carabine* Sir Samuel Meyrick says, "In the extraordinaries for the war in Picardie, in 1559, we first meet with the troops called carabins, who were light cavalry in the service of Henry II., King of France." M. de Montgommeri informs us that "they wore a cuirass sloped off the right shoulder, that they might the more readily couch their cheeks to take aim; that they had a cabasset on their heads, and their bridle-arms protected by an elbow gauntlet. Their offensive weapons were a carabine three feet and a half in length, so named from themselves and a pistol. Their manner of fighting was, to form a little column deeper than wide, to discharge their pieces rank after rank, each rank, after firing their pieces, wheeling off, and forming immediately in the rear of the rest, and there preparing for a second discharge." Now, although the origin of the word is involved in much obscurity, it is more consistent with analogy to suppose that the carabineers were so named from the gun, rather than that from them. The French derived this species of troops from the Spaniards; and Duetal tells us that the Calabrians, who used the carbine, gave it this appellation. If so, it was probably at first used by them at sea in the vessels termed carabs. M. Bellon, in 'Les Principes de l'Art Militaire,' tells us, that "the carabines were armed with a large wheel-lock arquebus, three feet or more in length, a sword, and a short pistol, in the time of Louis XIII.; but being suppressed by his successor in 1665, we know that that king formed from them his carabineers."

The *Esclopette.* "The peculiar characteristics of this fire-arm," says Sir Samuel Meyrick, "I have not been able to discover. It was called in Latin *sclopeta*, a diminutive of *sclopus;* and occurs in the 'Chronicon Estense,' under the year 1534, as well as in the decree of the Council of Tarragona in 1591, who forbade the clergy to make use of it. Probably it was only the foreign name of the demihaque."

"The name of the *Fusil* as a fire-arm in England," says the same authority, "does not appear to be older than the time of Charles II., though invented in France in the year 1630." There are in the British service three regiments of fusileers or fuzileers: the Scots, now the 21st Foot, raised in 1678; the English, now the 7th Foot, levied in 1685; and the Welsh, now the 23rd, formed in 1688 or 1689. The Sieur de Gaya, in 1688 ('Traité des Armes'), describes it as of the same proportions as the "mousquet," and furnished with a fire-lock; adding, that "although by couching the cheek you can take better aim, yet it often misses fire from the use of the flint." It seems to have been of the same length and calibre, but lighter than the musket. In modern times its size has been diminished.

The *Mousquetoon*, or musketoon, was also of French origin. The same author describes it, in 1688, as not so long as the fusil, nor capable of carrying a ball so far by one-third; its barrel not rifled, but differing from the carabine in being furnished with a fire-lock instead of a wheel-lock, and from the carabine *a l'extraordinaire* not only in this, but in its fluted bore.

The *Fowling-piece*, though properly speaking a fabrication for the sole purpose of killing game, is entitled to a place in the history of military weapons, from the circumstance of the Earl of Albemarle noticing it for the soldiers' use, in his 'Observations,' compiled about the year 1646, and published in 1671. He says, "It is very fit, likewise, that you have in each company six good fowling-pieces, of such a length as a soldier may well be able to take aim, and to shoot off at ease: twelve of them being placed in a day of battel, when you bring a division of foot to skirmish with an enemy, on the flanks of a division of foot, and six on the other flank, as you shall see them placed in these three battels following. Those soldiers that carry the fowling-pieces ought to have command when they come within distance of shot of that division of the enemy that they are to encounter with, that they shoot not at any but at the officers of that division." We have here plainly the origin of riflemen.

The President Fauchet, who lived in the time of Francis I., and that of his successors till the time of Henry IV., introduces to our notice a piece called a *Petronel* or *poitrinal*, because it was rested on the poitrine or chest, after the old manner, and thence fired. It was the medium between the arquebus and the pistol, and differed from the long dag merely in having its butt made broader, so as to rest in its position with proper firmness. Fauchet says, it was believed 'that this arm was the invention of the bandouliers of the Pyrenean mountains.' Mention is made of it in 1592, at the siege of Rouen by Henry IV., and in the Hengrave Inventory of 1603 we have, "Item, iij pethernels." Nicot, in his dictionary, asserts that "it was of large calibre, and, on account of its weight, carried in a broad baudrick over the shoulder."

The *Blunderbus.* This is a fire-arm shorter than the carbine, but with a wide barrel. Sir James Turner, in his 'Pallas armatá,' p. 137, thus describes it: "The carabineers carry their carabines in bandileers of leather about their neck, a far easier way than long ago, when they hung them at their saddles: some, instead of carabines, carry blunderbusses, which are short hand-guns of a great bore, wherein they may put several pistol or carabine balls, or small slugs of iron. I do believe the word is corrupted, for I guess it is a German term, and should be donderbucks, and that is, thundering guns, donder signifying thunder, and bucks a gun." Sir Samuel Meyrick remarks, that Sir James Turner is right in his etymology, except that "bus" and not "bucks" is the term for a gun, a name that became general after its introduction in the word arquebus: the modern German word is büchse. Blunderbus being called in the Dutch language *donderbus*, in all probability it was from Holland that the English derived it: it does not appear to have been much known before the time of Charles II.

The *Dragon.* The troops called dragoons have been most absurdly said to have been so denominated from the Draconarii of the Romans. They were raised about the year 1600 by the Mareschal de Brisac, in order to be superior to the German Reiters, who used the pistol to so much advantage. On this account they had a more formidable weapon, like a small blunderbus, the muzzle of which being ornamented with the head of a dragon, gave it its denomination, and from this weapon those who used it were called dragoneers and dragoons. Other, but less satisfactory, explanations of the term dragoon (with no reference to the fire-arm called a dragon) will be found in Sir James Turner's 'Pallas armatá,' in Pere Daniel's 'Milice Française,' and in Count Bismark. The dragon will be found among Skelton's engraved 'Illustrations.'

The *Hand-mortar* was used for throwing small shells and grenades; though grenades which are said to have been first used in 1594, were also thrown by the hand, and thence gave origin at a later date to the troops denominated grenadiers. Like the dragon it appears to have been fired from the shoulder.

The *Dag.* In pursuing the inquiry into the origin of this term, says Sir Samuel Meyrick, nothing could be more perplexing than to find, that while dag implied a kind of pistol, pistolese, in the Italian language, signified a great dagger, or wood-knife. The weapon appears to have been suggested by the demihaque, and differs from the pistol solely in the form of the butt end, that being invariably terminated by a straight oblique line instead of a knob. In this respect it greatly resembled a petronel, and that it gave the distinction is clear, from what is wrongly called a Highland pistol being by the Highlanders themselves termed a tack, and its having its butt made flat and terminated slant-wise. The dag was of various sizes, and hence in inventories of arms we meet with long, short, and pocket dags, and dags with different kinds of locks. It appears to have been almost coeval with the pistol, which is known to have been invented in the reign of Henry VIII.; for in the inventory, taken in 1547, of stores in the different arsenals in England, "one dag with two pieces in one stock" occurs, with "a white tacke with fier locke graver, and all the stocke white bone; two tackes, after the fashion of a dagger, with fier lockes vernished with redde stockes, shethes covered with blacke vellet garnished with silver and guilt, with purses, flaskes, and touch boxes of black vellet garnished with iron guilt; two tackes hafted like a kniff with fier lockes and double lockes," &c. The snaphaunce dag seems to be alluded to in the play of Jack Drum's entertainment

> "He would show one how to hold the *dag*,
> To draw the cock, to charge and set the flint."

The *Pistol*, according to Sir James Turner, was invented at Pistoia, in Tuscany, by Camillo Vitelli, and in the reign of Henry VIII. M. de la Noue says, "the reiters first brought pistols into general use, which are very dangerous when properly managed." These reiters, or more properly ritters, were the German cavalry, who gave such ascendancy to the pistol as to occasion in France, and subsequently in England, the disuse of lances. We learn this interesting fact from Davila, who, speaking of the battle of Ivry, in 1590, takes occasion to extol the use of lances, and express his regret that the French cavalry, composed of gentlemen volunteers, had, in the revolutions of the civil wars, ceased to use them. He tells us, that in consequence of their having adopted pistols as more ready, in imitation of the German reiters, the king was obliged to oppose the lances of the enemy's cavalry by dividing his own into small bodies, that they might offer less resistance to the charge, and more easily get out of the way. Père Daniel informs us, that the horsemen who were armed with pistols, in the time of Henry II., were thence called pistoliers, a term subsequently introduced into England. John Bingham, in his 'Notes on the Tactics of Ælian,' published in 1616, gives us an engraving of the arms and armour of this species of troops at that time, from which a correct knowledge may be obtained of their form. The first ordonnance of Henry II., king of France, respecting the pistol, is directed to the men at arms, and dated 1549; the regulations of Mary, Queen of England, were of a similar character; both implying that the adoption of the pistol, in the first instance, was by permission. The manual exercise of this weapon is detailed and exhibited in several plates in Captain Cruso's 'Military Instructions for Cavalry,' published in 1632. Sir James Turner, in his 'Pallas armata,' published in 1670, says, the French then used locks with half-bends (snaphaunces), as well as for the most part the English and Scots; the Germans, rose or wheel-locks; the Hollanders used both.

The *Trickerlock*. "A match tricker-lock compleat" occurs in a schedule of the year 1629. This was the adoption of what is now termed a hair-trigger, which was added to the former one, and gives a more instantaneous discharge. A tricker wheel-lock of the reign of Charles I., a tricker match-lock of that of Charles II., and a tricker fire-lock of that of James II., upon this principle, are preserved in Colonel Meyrick's collection of arms and armour at Goodrich Court, in Herefordshire.

The *Fire-lock*. Colonel Meyrick is in possession of a portrait of a republican officer, said to be that of Colonel Joyce, which proves that the modern firelock is an invention as early as the middle of the 17th century, for he has a firelock pistol in his hand. This is important evidence, for it has been shown that the name had been equally applied to the wheel-lock. The firelock was evidently suggested by the snaphaunce. It originated with the French about the year 1635. The steel post on which the furrowed piece had been placed was got rid of, and the furrowed piece set upright and fixed on the cover of the pan. The cock was moved sufficiently near to permit its opening the pan, by the sudden impulse on striking this furrowed piece; performing this operation, and giving fire at the same time. Such a firelock of the time of Cromwell will be found among Skelton's engravings. The term firelock was no longer applied to the fire-arm with the wheel, which was now termed "the rose or wheel-lock."

The *Self-loading Gun* originated in Italy about the close of the English Protectorate. The butt was made to answer the purpose of a flask, and a small touch-box was attached to the pan. At the breach was a cylinder, with a hole to receive the bullet. To the axle of this cylinder was affixed a lever, on turning which the bullet was conveyed to its proper place: sufficient portions of charge and priming were cut off, and the piece cocked at the same time. This, therefore, rendered the firelock just described as expeditious as the long-bow; but the contrivance was attended with great danger, and occasioned the subsequent inventions of a moveable or revolving breach composed of several cylinders, each containing a charge; or a small barrel to be brought to the breach when requisite to load, &c. Though none of these contrivances were ever adopted by infantry regiments, yet some of them were extremely ingenious, being a very close approach to our modern revolver pistols.

In 1712, a brass fire-arm called the *Fancy gun* was invented. It was in the shape of a walking-cane, and might be used as a gun or pistol; but it was never used for military or even general purposes.

Musket-Arrows, sometimes called fire-arrows, are at least as old as the time of Queen Elizabeth. They occur in the inventories of the royal arsenals. Sir Richard Hawkins, in the account of his voyage to the South Sea in the year 1591, speaks of using them with great success. In Elizabeth's time, these arrows, which carried combustibles, were of wood; at a subsequent period they were made of iron. Arrows of this latter kind were used in the Civil Wars, at the siege of Lyme. Lord Bacon says the arrows shot by muskets were called sprights.

The *Match-box*. One great inconvenience, says Sir Samuel Meyrick, of the burning match was, that it discovered the soldier on guard, and counteracted the necessary secrecy for enterprises by night. To remedy this defect, small tubes of tin or copper, pierced full of holes, were invented by a Prince of Orange, apparently Prince Maurice. They are thus described by Walhuysen, a captain of the town of Danzig, in his 'Art Militaire pour l'Infanterie,' printed in 1615: "It is necessary that every musqueteer should know how to carry his match dry in moist or rainy weather, that is, in his pocket or in his hat, by putting the lighted match between his head and hat, or by some other means to guard it from the weather. The musqueteer should also have a little tin tube, of about a foot long, big enough to admit a match, and pierced full of little holes, that he may not be discovered by his match, when he stands sentinel, or goes on any expedition." This was the origin of the match-box, till lately worn by our grenadiers on one of the cross belts in front of their chests.

The *Powder-horn* and *Flask*. The convenient form of the horn to hold gunpowder, one end being broad, into which it might be conveyed with ease, and the other with a small aperture by which it might be discharged into the barrels of fire-arms, naturally suggested it as best adapted for the purpose. But it was not long before the narrow end was entirely closed, and the broader one furnished with a tube that might contain just sufficient power for one charge. In this state it appears suspended in front from the necks of the arquebusiers in the triumph of Maximilian I. This modification of the powder-horn suggested the more capacious flask, which, with its name, in reference to its resemblance to a bottle, is of German origin. The flask was known in England as early as the reign of Henry VIII., and appears on a hackbutter of that date in one of Strutt's engravings, taken from an original drawing in the British Museum, suspended like the horn, but at the hip, instead of on the breast. So in the inventory, taken 1 Edward VI., we have "One horne for gonne-powder, garnished with silver. Three grete flaskes covered with vellet, and three lytle touch boxes." And in that at Hengrave, "xxiiij flaskes, and as many tootche boxes." M. Montgommeri Corbosson, in his 'Treatise on the French Army' in the time of Henry IV., informs us that "the captain of a company, mounting guard, ought to carry an arquebuse and a powder-flask, and wear on his head a great plume of feathers." Varieties of powder-horns and flasks will be found in Skelton's engravings.

The *Touche-box*. Gunpowder was at first not corned; when, however, it had been manufactured into granules, such as were considered proper for the charge, it was discovered that the finer these were made the quicker would they ignite. This was the origin of priming or serpentine powder, and consequently of a small case to hold it, which is in reality a flask on a smaller scale, to which the name given was touche-box.

Bandoliers. To enable the soldier to load his piece with greater rapidity, small cylindrical boxes, each containing one charge of powder, either of wood or tin, and covered with leather, were suspended to a belt or band, put either over the shoulder or fastened round the waist. They seem to have been first introduced in the reign of Henry III. of France. The earliest instance which Sir Samuel Meyrick met with of the bandolier was in Montfauçon's 'Monarchie Françoise,' pl. ccxciv.; Davis, in his 'Art of War,' he says, would induce the belief that the English received them from the Walloons in the neighbourhood of Liege. Sometimes six were placed before, and six behind the person, when slung over the shoulders; sometimes more. Nine are suspended to a waist-belt in Col. Meyrick's collection. Immense numbers still remain at Hampton Court. Sir James Turner, who published his work in 1670, says they were first laid aside about thirty years before by the Germans. Soldiers who were without cloaks could not keep them from snow and rain, which soon spoiled them and made the powder useless; and in surprisals, the noise which they made betrayed those who carried them.

The *Cartridge*. Sir James Turner, speaking of the pistol, says, "all horsemen should always have the charges of their pistols ready in patrons, the powder made up compactly in paper, and the ball tied to it with a piece of packthread." In this description we have evidently the cartridge, though not expressed by name. It is a curious fact that these were first confined to the cavalry, and that the general adoption of the cartridge was not earlier than the common use of the modern firelock. Lord Orrery, in his 'Treatise on the Art of War,' says, "I am, on long experience, an enemy to the use of bandeleers, but a great approver of boxes of cartridges, for then, by biting off the bottom of the cartridge, you charge your musket for service with one ramming. I would have these cartridge-boxes of tin, as the carabiners use them, because they are not so apt to break as the wooden ones are, and do not in wet weather, or lying in the tents, relax. Besides, I have often seen much prejudice in the use of bandoleers, which, being worn in the belts for them above the soldiers' coats, are often apt to take fire, especially if the matchlock musket be used; and when they take fire, they commonly wound and kill him that wears them, and those near him; for likely, if one bandoleer take fire, all the rest do in that column; they often tangle those which use them on service, when they have fired, and are falling off by the flanks of the files of the intervals to get into the rear to charge again."

The *Patron* was an upright semi-cylindrical box of steel, with a cover moving on a hinge, filled with a block of wood with five perforations to hold as many pistol-cartridges. Skelton has engraved some of Elizabeth's time, and in the 'Diversarum Gentium Armatura Equestris,' printed in 1617, the German cavalry are represented with a brace of pistols in the same holster at the saddle-bow, and patrons at their hips.

The *Sweynes-feather*, and *Musket-rest*. To remedy the inconvenience of a musketeer's being compelled to draw his sword, and to defend himself after the discharge of his piece, and to render him more competent to act against the pikemen, a long thin rapier blade, fixed into a handle, and carried in a sheath called a sweynes-feather, that is, hog's bristle, the invention of which is by its other name attributed to the Swedes, was given him instead. This, after a discharge, he drew out of its scabbard, and fixed into the muzzle of his gun, which gave him a weapon of great length; but as the soldier had then more to carry in his hand than previously, an attempt was made to unite the sweynes-feather with the rest. This latter, instead of having a wooden shaft simply, was made of a thin tube of iron, covered with leather, which held within it the feather. Thus it was preserved from rain, and when wanted, it could be ejected by a jerk. The sweynes-feather was invented in the reign of James I. During the civil wars, its name was sometimes corrupted into swan's feather. One of the musket-rests, armed with a projecting pike from one of the prongs of its fork, is represented in Grose's 'Treatise on Ancient Armour,' pl. xl. fig. 5. The Duke of Albemarle, in his 'Observations upon Military and Political Affairs,' written in 1646, and printed in 1675, recommends arming musketeers and dragoons with muskets and sweynes-feathers, with the heads of rests fastened to them. The rests themselves were apparently disused about the middle, or toward the latter end of the civil wars, the weight and incumbrance of the musket and its apparatus being probably found too great for the active service inseparable from campaigns carried on by small detachments.

The *Bayonet*. Sir Samuel Meyrick observes, that as the sweynes-feather was laid aside when the rest which contained it was relinquished, the musketeers were reduced to the same inconvenience as they experienced before it had been invented. To resume the simple sweynes-feather was not deemed expedient, as from its length it was extremely awkward to manage, and pikemen were a species of troops that had become disused. This induced such soldiers as were armed with daggers to stick them into the muzzles of their pieces after having fired. In this practice we have the origin of the bayonet, which was so termed from having been first made at Bayonne. The French called them bayonet à marche, and first introduced them into their army in 1671. These were formed with plain handles, formed to fit tight into the muzzles, rather enlarging towards the blade to prevent their entering too far into the piece. Subsequently a ring was added, by which it was placed on the muzzle, in which way the French used it in the reign of William III., to the astonishment of the 25th regiment of foot, on whom they poured a volley, halting in their charge.

The arms at present used will be described under their respective heads MUSKET; RIFLE; &c., and the arming of the various branches of the service under INFANTRY; CAVALRY; &c.

Besides the authorities quoted in this article, Grose's 'Military History;' Strutt's 'Manners and Customs,' and the various authors quoted by them, may be referred to.

ARMS, COATS OF. [HERALDRY.]

ARMS, STAND OF, means the complete set of arms for one man, namely, musket and bayonet, belts, cartridge-box, &c.

ARMY, THE ENGLISH. The word *army* is derived from the French *armée*, from which language many of our military terms are taken. It is applied to an armed, and more or less disciplined, body of men. An army is defined by Locke to be a collection of armed men obliged to obey one man. There are, however, various definitions given by writers on the Law of Nations.

The word army is not used to designate a single regiment or battalion, or any small body of armed men. An army is a large body of troops of all arms, accompanied by their trains of stores and materiel, divided for the purposes of organisation into divisions, brigades, and regiments, each under its own special commander, and having officers of various descriptions to attend to all that is necessary to make the troops effective when in action; the whole body being under the direction of some one commander, and moving according to his orders. This officer is called the commander-in-chief, the general, and sometimes, as when two or more allied armies are under the chief direction of one of the generals, the generalissimo.

We may briefly explain why we limit this article to a sketch of the origin of the English army, without including, as is sometimes done in similar works, an historical sketch of the armies of ancient nations. The armies of Greece, Rome, and the ancient Oriental nations, were, owing to various causes, different from those of modern Europe, and the consideration of their true character belongs to the history of those nations. From the impossibility of saying anything satisfactory within reasonable limits, and also from a desire to avoid the errors which we observe in all short sketches of this description, we have, under such heads as GREEKS, ROMANS, EGYPTIANS, &c., noticed their military system, so far as it possesses a distinct character.

The history of the armies of continental Europe, as, for instance, that of Prussia, is inseparably connected with the political history of each state, and has been treated under those heads in the GEOG. DIV. of ENG. CYCL. For other particulars connected with the formation of an army, see ENLISTMENT, RECRUITING, SOLDIER, and also MILITIA.

The whole military force of a nation, comprising its regular or standing army, militia, and volunteers, is sometimes called its army, though generally this term is confined to its standing army. In another sense, an army is a detachment from the whole collected force; a number of regiments sent forth on a particular expedition under the command of some one person who is the general for that especial purpose. Instances of this latter sense of the word occur in the expressions 'Army of Italy,' 'the Army of Spain,' &c., as formed by Napoleon. Such a detachment may be a large or a small army; and should it return with its ranks greatly thinned and without many of its officers, it would still be an army, if the distribution into divisions and regiments remained, though actually consisting of not more than a single regiment with its full complement of men and officers. In this state it is sometimes not inaptly called the skeleton of an army.

An army is the great instrument supported by a nation and placed in the hands of its government, by which in the last extremity it maintains the constitution at home by enforcing obedience to its laws, and supports the honour of the country abroad, by defending its rights against any powers which may show a disposition to encroach on them. When the efforts of the ministers of peace and justice are inadequate to enforce submission to the laws; when the correspondence of cabinets and the conferences of ambassadors fail in composing disputes which arise among nations, the army is that hand of power which is then legitimately put forth. This powerful engine has, however, but too often been used for baser purposes; not only for aggression and unprovoked attacks against the liberties of other countries, but, when in the hands of unprincipled men, for the subversion of the constitution and liberties of their own countries. Thus was it in Rome in ancient, and France in modern, times; and thus will it always be, when the ranks, from which its officers are recruited, have no stake in the country, and being dependent solely on their profession, become a separate caste without community of interest with the rest of the nation.

The legitimate purposes for which an army is maintained are manifestly so important to the well-being of a state, that attention must have been directed to this subject in the very beginning of political society. But to have an army always appointed and always ready for the field can only be effected in a comparatively high state of civilisation, when the whole machinery of state is well organised, by maintaining a regular or standing army as distinguished from a militia which is capable of being called out merely for a temporary exigency. No better proof can be afforded of the high civilisation of Egypt and other countries in early times than the well-appointed and powerful armies which they were able to bring into the field. This was effected in Egypt by having a particular caste or class of soldiers, corresponding pretty nearly to the Kshatriyas of India. (See Herod. ii. 164, &c.) The army raised by Sesostris seventeen centuries before our era, which is the earliest military establishment of which we have any record, is stated by Diodorus Siculus, to have been composed of 600,000 infantry, 24,000 cavalry, and 27 war chariots, though this is probably an exaggerated estimate, if one may judge from the size and population of the country. The armies of the Greeks, especially in the post-Alexandrine period, those of Carthage under the command of Hannibal, and the armies of Rome in the best days of the Republic and the Empire, were not inferior to any of modern times in numbers, appointments, discipline, or the military skill of their commanders, and were essentially standing armies. It is not, however, to them that we are to trace the origin or the history of our modern armies.

An army, meaning by that term a body of men distinct from the rest of the nation, constantly armed and disciplined, was unknown to the remote fathers of the English and the other modern European nations. The whole male population was the army; that is, every person learned the use of arms, was ready to defend himself, his family, and his possessions; and in time of common danger, to go out to more lasting warfare under the command of some one chief chosen from amongst the heads of the tribes. Such was the nature of the vast armies which presented themselves from time to time on the Roman frontier, or contended against Cæsar when he made his conquest of Gaul; and such was the power which, on so short a warning, was arrayed against him on the British coast under the command of Cassibelaunus, when he made that descent from which neither honour accrued to the Roman arms, nor benefit to the Roman state. In all these nations the warlike spirit was kept up by the sense of danger, not so much from foreign invaders, as from neighbouring and kindred tribes.

In the writings of Cæsar and of Tacitus, the two authors from whom we derive our best acquaintance with the manners and habits of the Germanic and the western nations of Europe, we see the warlike character of those nations, and the principles on which their military affairs were conducted. A whole male population trained to arms; confederating in time of common danger under some one chief; with little defensive armour, and none offensive but darts, spears, and arrows; throwing up occasionally earth-works to strengthen a position —this is the outline of their military proceedings. (Tacit. 'Annal.' ii. 14.) There is little peculiar in the military system of the ancient Britons; yet it must have been by long practice and perseverance that the warriors attained that skill which attracted the attention of Cæsar. His description of one of their chariots, driven by a charioteer whose attention was solely directed to the management of the chariot, while in it stood the painted warrior dealing his darts around him, or running along the beam while the chariot was in its swiftest motion, presents an object at once picturesque and terrible.

When Britain was reduced to the form of a Roman province, a regular army was introduced and permanently settled in the island, for the purpose of enforcing submission, and of defence against foreign invaders. Almost all the remains of Roman authority in Britain, as roads, walls, encampments, and inscriptions, are military. In that curious relic of Roman time, the 'Notitia,' which is referred to the age of the Roman emperors, Arcadius and Honorius, we have a detailed account of the distribution of the whole Roman army, and we see, in particular, how Britain was then divided for military purposes, and what were the fixed stations of the various portions of the Roman legions.

It was the policy of Rome to recruit her legions from among the barbarous nations, but to employ such soldiers in countries to which they were foreign. Thus, in the inscriptions relating to military affairs which have been found in England, many tribes of Gaul, of Spain, and Portugal, are named as those to which particular soldiers or particular bodies of troops belonged. And so in foreign inscriptions the names of British tribes are sometimes found. The grounds of this policy are apparent. The military portion of these nations was thus drawn away. There remained only the quiet and the peaceable, or the females, the young, the infirm, and the aged. As long as the Roman army was sufficient for their protection, it was well. But when that army was withdrawn, we see, as in the case of Britain, that a people so weakened easily fell a prey to nations which had never been subdued by the Roman arms, and we see also what was probably the true reason of the difference between the spirited resistance which was made to Cæsar on his two landings in Britain, and the clamorous complaint and feeble resistance with which the people of Britain met the Picts and the Saxons.

From this time we lose sight of any entire British population of the part of the island called England. The conquests made by the Saxons appear to have been complete, and their maxims of policy and war became the principles of English polity. They seem to have been at first in that state of society in which every man is a soldier; and the different sovereignties which they established were the occasion of innumerable contests. We have, however, but little information on this subject; and even the supposed policy of Alfred in the separation of a portion of the people for military affairs, in the form of a national militia, is a part of his history on which we have not any very satisfactory information.

We find, however, that the Saxon sovereigns had powerful armies at their command; and the most probable account of the mode in which they were got together seems to be this:—the male population were exercised in military duties under the inspection of the earls, and their deputies the sheriffs or vicecomites, in the manner of the arrays and musters of later times; being drawn out occasionally for the purpose, and being thus ready to form, at any time when their services were required, an efficient and powerful force.

In the year 1017 Canute became king of England, and established the first regular army of which we have any record in the middle ages. Hallam states ('Middle Ages,' vol. i. ch. 2, part 2) that he is unaware of any instance of what may be called a regular army (unless we consider the Antrustions of the Merovingian kings as such), more ancient than the body guards, or huscarles of Canute the Great. These select troops amounted to six thousand men, on whom he probably relied to ensure the subjection of England. A code of martial law, compiled for their regulation, is extant in substance; and they seem to have displayed a spirit of military union of which their master stood in awe. A singular story is told, which, if false, still illustrates their traditionary character. Canute having killed one of their body in a fit of anger, it was debated whether the king should incur the legal penalty of death; and this was only compromised by his kneeling on a cushion before the assembly, and awaiting their permission to rise. (Hallam's 'Middle Ages,' note, vol. i. ch. 2, part 2.)

The next remarkable instance of a mercenary army is that of William the Conqueror; and we see from that curious remain of those times, a piece of needlework representing the wars and death of Harold, that the Saxon soldiers were not those half-clothed and painted figures which had presented themselves on the shores of Britain when the Roman armies made their first descent. We see them clothed from head to foot in a close-fitting dress of mail. They have cavalry but no chariots. The archers are all infantry. Both infantry and cavalry are armed with spears, to some of which little pennons are attached. Some have swords, and others carry bills or battle-axes. They have shields, the bosses on which are surrounded with flourishes and other ornaments; and there are sometimes other devices, but nothing which can be regarded as more than the very rudiments of those heraldic devices which were afterwards formed into a kind of system by the heralds who attended the armies, and by which the chiefs were distinguished from each other, when their faces were concealed by their vizors. The piece of needlework representing the wars of Harold is supposed to be the work of Matilda, the queen of William the Conqueror, and the ladies of her court. It is preserved in the cathedral of Bayeux, whence it is commonly called the Bayeux tapestry. [Bayeux Tapestry.]

In the 9th century a great change took place in the military policy of Europe. Feudal military tenures succeeded that earlier system of public defence which called upon every man, and especially every landholder, to protect his country. The hordes of barbarians, who, issuing from Germany, had spread over Europe and overthrown the Western Empire, had divided the greater portion of the conquered lands among themselves. And each allotment was given as a reward for, and was held on condition of, military service under the chief or lord of whom the land was immediately held. To him fealty was sworn, and whenever called upon the holder was obliged to follow him to the field. Hence arose the feudal system. An aggregation of petty sovereignties; the lords with trains of vassals constantly making war on one another and owing but little obedience to their sovereign, to whom they in their turn had sworn fealty, unless he happened to be powerful enough to enforce it.

At the conquest this feudal system was introduced into England with this remarkable difference: "By the leading principle of feuds, an oath of fealty was due from the vassal to the lord of whom he immediately held his land, and to no other. But William received at Salisbury, in 1085, the fealty of all landholders in England, both those who held in chief and their tenants." (Hallam, vol. ii. ch. 8, part 2.) Thus placing the army far more under his own control. William, reserving certain tracts as his own demesne, distributed the greater portion of England among his followers, to hold by military service; that is, for every knight's fee, as it was called, the tenant was bound to find the king one soldier ready for the field, to serve him for forty days in each year. The extent of the knight's fee varied with the varying qualities and value of the soil. In the reign of Edward I. the annual value in money was 20*l*. The number of knights' fees is said by old writers to have been 60,060. The king had thus provision made for an army of 60,000 men, whom he could call at short notice into the field, subject them when there to all the regulations of military discipline, and keep them for forty days without pay, which was usually as long as their service would be required in the warfare in which the king was likely to be engaged. When their services were required for any longer time, they might continue on receiving pay.

Writs of military summons are found in great abundance in what are called the 'Close Rolls,' which contain copies of such letters as the king issues under seal. But this system, it is evident, had many inconveniences; and the kings of England had a better security for the protection of the realm against invasion and for the maintenance of internal tranquillity, in that which seems to be a relic of Saxon polity. We allude to the liability of all persons to be called upon for military service within the realm; to the power which the constitution gave to the sheriff to call them out to exercise, in order that they might be in a condition to perform the duty when called upon; and to the obligation which a statute of Edward I. imposed on all persons to provide themselves with certain pieces of armour, which were changed for others by a statute of James I. We see in this system at once the practice of our remoter ancestors, and the beginning of that drafting of men to form the county militia which is a part of the military polity of the country at present.

The sheriffs were the persons to whom the care of these affairs was committed; but it was the practice of the early kings to send down into the several shires, or to select from the gentry residing in them, persons whose duty it was to attend the musters or arrays, which were a species of review of these domestic troops, and who were intended, as it seems, to be a check upon the sheriffs in the discharge of this part of their duty. The persons thus employed were usually men experienced in military affairs; and when the practice became more general, there was a permanent officer appointed in each county, who had the superintendence of these operations, and was called the lieutenant: this is the origin of the present lord-lieutenant of counties, an officer who cannot be traced to a period earlier than the reign of Henry VIII.

Foreigners were also sometimes engaged to serve the king in his wars; but these were purely mercenary troops, and were paid out of the king's own revenues.

We see then that the early kings of England of the Norman and Plantagenet races had three distinct means to which they could have recourse when it was necessary to arm for the general defence of the realm: the quota of men which the holders of the knight's fees were bound to furnish; the posse-comitatûs, or whole population, from sixteen to sixty, of each shire, under the guidance of the sheriffs; and such hired troops as they might think proper to engage. But as the posse-comitatûs could not be compelled to leave the kingdom, and only in particular cases the shire to which they belonged, the king had only his feudal and mercenary troops at command when he carried an army to the Continent, or when he had to wage war against even the Scotch or Welsh. We are not to suppose that troops so levied, especially when there were but contracted pecuniary resources for the hiring of disciplined troops of other nations, would have been sufficient to make head against the power of such a sovereign as the king of France, and once to gain possession of that throne. And this leads us to the next great innovation, marking the third period in the military history of England; for about the 13th century mercenary troops were substituted for the feudal militia.

The mutual inconveniences attendant on the nature of the military services due from those who held the feudal tenures of the crown naturally disposed both parties to consent to frequent commutations. Money was rendered instead of service, and thus the crown acquired a revenue which was applicable to military purposes, and which was expended in the hire of native-born subjects to perform service in the king's armies in particular places and for particular terms. The king covenanted by indenture with various persons, chiefly those of most importance in the country, to serve him on certain money-terms with a certain number of followers, and in certain determinate expeditions. There appears little essential difference between this and the modern practice of recruiting armies. It was chiefly by troops thus collected that the victories of Creci, Poictiers, and Agincourt were gained.

In the office of the Clerk of the Pells in the Exchequer, Dugdale perused numerous indentures of this kind, and has made great use of them in the history which he published of the Baronage of England. A few extracts from that work will show something of the nature of these engagements.

Michael Poynings, who was at the battle of Creci, entered into a contract with King Edward III. to serve him with 15 men-at-arms, 4 knights, 10 esquires, and 12 archers, having an allowance of 21 sacks of the king's wool for his and their wages. Three years after the battle of Creci, King Edward engaged Sir Thomas Ughtred to serve him in his wars beyond sea, with 20 men-at-arms and 20 archers on horseback, taking after the rate of 200*l*. per annum for his wages during the continuance of the war. In the second year of King Henry IV., Sir William Willoughby was retained to attend the king in his expedition into Scotland, with 3 knights, besides himself, 27 men at arms, and 169 archers, and to continue with him from June 20th to the 13th of

September. When Henry V. had determined to lead an army into France, John Holland was retained to serve the king in his 'voyage royal' into France for one whole year, with 40 men at arms and 100 archers, whereof the third part were to be footmen, and to take shipping at Southampton on the 10th of May next following. At the commencement of the 15th century, we find mentioned in Rymer a contract of the Earl of Salisbury, to supply a body of troops for the war in France, consisting of 600 men at arms, including 6 bannerets, 34 bachelors, and 1700 archers. The pay was, for the earl, 6*s.* 8*d.* a-day; banneret, 4*s.*; bachelor, 2*s.*; every man at arms, 1*s.*; and every archer, 6*d.* Artillerymen were paid higher than men at arms. This is equal to about fifteen times the sum at our present value of money. They were however bound to furnish their own equipment and horses. In the 12th of Henry VII., John Grey was retained to serve the king in his wars in Scotland, under the command of Giles, Lord Daubeney, captain-general of the king's army for that expedition, with 1 lance, 4 demi-lances, and 50 bows and bills, for 290 miles; with 1 lance, 4 demi-lances, and 50 bows and bills, for 266 miles; and with 2 lances, 8 demi-lances, and 200 bows and bills, for 200 miles. These were nearly half what is now the usual complement of a regiment.

Troops thus levied, together with foreign mercenaries, are a near approach to, though they can hardly be considered as, a regular or standing army in the modern acceptation of the word. The king might, to the extent of his revenue, form an army of this description; but as to the other means of military defence or offence put into his hands, the persons engaged were only called into military service on temporary occasions, and soon fell back again into the condition of the citizen or agriculturist. But the king's power was necessarily limited by his revenue, and the maintenance of a permanent force appears to have been little regarded by our early sovereigns, since, before the reign of King Henry VII. it does not appear that the kings had even a body-guard, much less any considerable number of troops always prepared for service. About the year 1450, Charles VII. of France established his companies of ordonnance; they consisted of about 9000 soldiers, all cavalry, of whom 1500 were heavy armed: a force not very considerable, but yet stated by Hallam to be the first, except mere body-guards, which had been raised in any part of Europe as a national standing army. From this we may date the fourth period in the military history of Europe, and of England also. Chivalry began to decline; and in the 16th century the importance of infantry was fully established by the Milanese wars of Louis XII. and Francis I., and caused the general employment of pikemen and musketeers.

The policy of standing armies was gradually imitated by the other European states, and has now become a matter of necessity and of self-defence. In England, probably in a great degree owing to her insular situation, this took place later than in most Continental countries. Still, the example of the Continental states, a sense of the great convenience of having always a body of troops at command, and the change in the mode of warfare effected by the introduction of artillery, which brought military operations within the range of science, and made them more than before matters which required much time and study in those who had to undertake the direction of any large body of men, disposed the king and the nation generally to adopt the practice of having a permanent army, varying in numbers with the dangers and necessities of the time.

The few troops who formed the royal guard were the only permanent soldiers in England before the civil wars. The dispute between Charles I. and his parliament was about the command of the militia. Charles II. kept up about 5000 regular troops as guards, and to serve in the garrisons which then were established in England. These were paid out of the king's own revenue. James II. increased them to 30,000; but the measure was looked on with great jealousy, and the object was supposed to be the destruction of the public liberties of Englishmen. In the Bill of Rights (1689) it was declared that the raising or keeping a standing army within the kingdom, in time of peace, unless it be with consent of Parliament, is against law; and this continues to be the preamble of the Mutiny Acts to the present day. An army varying in its numbers has ever since been maintained, and is now looked on without apprehension. It is raised by the authority of the queen, and paid by her; but there is an important constitutional check on this part of the royal prerogative in the necessity for Acts of Parliament to be passed yearly, in order to provide the pay and to maintain the discipline.

The present regular army of England is maintained by voluntary enlistment, and is composed of cavalry, infantry, artillery and engineers, and a military train. Attached to the army are the following departments:—the Commissariat and Medical (including Purveyors and Veterinary departments), Field Train, Military Store, and Barrack departments.

By the English constitution, the sovereign is the supreme head of the army, from whom alone it receives all orders, and by whom all promotions are made and all honours and rewards conferred, all commissions being under her sign manual. This authority is in part delegated to the commander-in-chief, who has the general superintendence of the organisation and discipline of the army, whilst the general superintendence of the War department is under the secretary of state for war, who is answerable to Parliament, and is responsible for the finances, &c.

Of the English army, besides that which is distributed in the various colonies, a large portion is employed in India, and whilst there is paid out of the finances of that country; in addition to which, the Indian army, consisting of cavalry, infantry, artillery, engineers, &c., formerly raised and paid by the East India Company, is now transferred to the queen, and is called 'The Queen's Army for Service in India.'

The following tabular view of the military force of the various civilised nations is from the 'Almanach de Gotha' for 1859, with some few corrections:

MILITARY ESTABLISHMENTS ON FOOT AND IN RESERVE. 1857, 1858.

	Estimated Population.	Army.	Reserve Militia and National Guard.
America, United States of, 1857	27,797,403	15,764	2,125,358
Austria, pop. 1854, army 1858, peace establishment of, being raised from the reserve to between 700,000 and 800,000	39,411,309	400,000	
Baden, pop. 1852	1,356,943	7,691	6,976
Bavaria, pop. 1855, army 1858	4,541,556	88,227	157,924
Belgium, pop. 1856	4,529,461	74,318	27,131
Brazil, pop. 1856	7,677,800	22,586	26,000
Denmark, pop. 1858	2,650,000	45,138	
Egypt, pop. 1857	2,895,550	21,000	
France, pop. 1856, army 1859	36,039,364	320,000	
,, Foreign possessions	3,506,218	93,000	
,, Rome		9,000	
Great Britain, pop. 1857, army 1858	28,416,056	222,874	
,, E. Indies, native troops (1857)	187,515,148	263,949	
Greece, pop. 1855	1,045,232	9,686	
Hanover, pop. 1855	1,819,777	26,938	
Netherlands, pop. 1858	3,523,823	58,495	
,, Foreign possessions	16,536,761

ARNICIN. The non-azotised, bitter principle of arnica flowers, *Arnica montana.* It has not been investigated.

ARNOTTO (*Annatto*). A pasty colouring matter obtained from the seed-pulp of the *Bixa Orellana*, a plant found in the West Indies. The colouring matter is prepared by kneading the pulpy seeds in warm water; the liquid is then passed through fine sieves, evaporated to the consistence of a stiff paste, and lastly dried in the shade. It is afterwards made into small cheese-shaped cakes, which soon become yellow outside, but retain a red-brown colour within. According to John, it contains 28 per cent. of coloured resin, 20 of coloured extractive matter, 26 of gum, and 20 of vegetable fibre, together with free acid, and an aromatic substance to which the peculiar odour of arnotto is due. Chevreul describes two colouring matters in arnotto; one yellow, soluble in water and alcohol; and another red, soluble in alcohol, and slightly so in water. Caustic alkaline solutions are tinged of a dark orange colour by arnotto. Alum and protosulphate of iron give orange yellow precipitates in decoction of arnotto, whilst protochloride of tin gives a lemon-yellow precipitate.

Arnotto imparts an orange colour to wool, cotton, and silk; but its use is now chiefly confined to silk-dyeing. The colour is brilliant, but fugitive. It is also employed to colour cheese and butter, and to impart an orange-yellow colour to varnishes, oils, tinctures, &c.

The Arnotto of commerce is brought to us from South America. It is moderately hard, brown on the outside, and of a dull red within. It comes in cakes of about two or three pounds weight each, and is generally enveloped in large flag-leaves previous to being packed in casks. It this state it receives the name of "flag arnotto," to distinguish it from another preparation which is a harder and more concentrated extract from the fruit-pods of the same plant, and which contains a larger proportion of colouring matter than flag arnotto. This superior description, of which but little is imported, is known as "roll arnotto.' The liquid sold under the name of Nankin dye—now, by the fluctuations of fashion, little used in England—is a solution of arnotto in potass and water. A solution is also sometimes made in alcohol, which is used for lacquering and by varnishers.

It is believed that the method employed for making this extract in the country of its production, which is by the application of a high degree of heat in combination with a process of fermentation, is injurious to its colouring properties: an opinion which is confirmed by the fact of the superiority of the colouring matter when procured from the fresh pods. There is reason to suppose that means might be used for precipitating the colouring matter without subjecting it to so great a risk of carbonisation by heat as it is usually made to undergo, and without having recourse to the process of fermentation. Some experiments made with this view by Vauquelin seem to confirm this supposition.

AROMATICS are agents obtained from the vegetable kingdom, exercising a peculiar influence over the digestive powers, and possessed of more or less odour or fragrance. Of this odour, by which they can at all times be recognised, the most usual vehicle is an essential or volatile oil, as stated in the article AROMA, in NAT. HIST. DIV. Indeed volatile oil exists in all aromatic plants, and in every part except the cotyledons, save in the nutmeg and a very few other seeds; but this aromatic oil does not reside in the same part in every kind of plant. In umbelliferous plants we find it mostly in the fruits (and chiefly in the *vittæ* of them), yet in angelica, celery, and parsley it is diffused through the whole structure. Labiate plants, such as mint, balm, rosemary, and lavender, have it in the leaves and stem; cinnamon in the bark; all terebinthinate plants in their young branches. The *Iris florentina* (orris) and others have it chiefly in the root; the *Scitamineæ* equally in the root (ginger) and the seeds (cardamoms); the rose and chamomile have it in the petals; yet it is not equal in all the petals of the chamomile, being greatest in the yellow florets of the disk: hence, doubling the flowers of the chamomile, by which the yellow florets of the disk are diminished, and the white florets of the ray increased, lessens the virtues of the flowers.

The power of medicines is frequently judged of by their sensible qualities; that is, by the impression which they make on the organs of smell and taste; aromatics affect both of these senses in a very perceptible and sometimes extraordinary manner. Scarcely any one is insensible to the odour of particular flowers, and some are affected by them to an extraordinary degree. The approach to Ceylon can be determined by the fragrance of the air, at the distance of many miles; the *Magnolia glauca* (beaver-tree or swamp magnolia) diffuses an odour by which it can be recognised at the distance of three miles among the swampy districts and consequently moist atmosphere in which it grows. This powerfully affects many persons while travelling or hunting; and the *Magnolia tripetala* causes sickness, headache, and an aggravation of fevers or rheumatism, among those near it who are labouring under these complaints. The odour of the jonquils and other fragrant plants raised in Holland is so great when brought into a room or close apartment as to be quite overpowering. In such countries or places as have a very humid atmosphere, the odour of plants is most readily diffused as well as most potent; of this we may satisfy ourselves by calling to mind the greater fragrance of flowers early in the morning, in the evening, or after a shower. This accounts for the violent action of the plants in the countries just mentioned; but even many plants of Britain affect some individuals, endowed with a peculiar and excessive sensibility, to an extreme degree. The sweet-scented violet has such an effect on certain persons as to occasion headache, convulsions, and apoplexy. (See Triller, 'Dissertatio de Morte Subita ex nimio Violarum Odore.')

Aromatics are seldom applied to the organ of smell for the purpose of influencing the system in a remedial manner, except in the form of aromatic vinegar, in threatened or actual fainting; we shall therefore proceed to consider their action upon the palate and stomach. As all aromatics contain volatile oil, their action is generally referred to this principle; but there cannot be a doubt that the more fixed principles which they contain contribute greatly to their effect. Volatile oils, when separated, act chiefly on the nervous system; but aromatics influence more particularly the digestive organs, the function of assimilation, and the generation of animal heat. They are themselves digested, but previous to this process commencing, or going any length, they produce, by direct contact with the internal surfaces, a peculiar effect, which we perceive beginning at the lips and palate, and accompanying them in their progress to the stomach. They scarcely excite any general action of the system, but expend their power chiefly upon the stomach, and, in a less degree, upon the intestinal canal, increasing the vital force of the former, and quickening the muscular action of the latter. They also communicate to the stomach a greater power of resistance to unpleasant sensations, as under their influence many articles can be borne by it which would otherwise be rejected; and this happens equally with regard to food and medicines.

The mixture of aromatics renders them more agreeable than when given singly; and this is exemplified both in their medical and culinary employment, as no good cook will use only one spice if she can procure more. The *aromatic powder* and *aromatic confection* are compounded on this principle for medical use, and Dr. Kitchener's Zest for culinary purposes.

The necessity for the employment of aromatics is greater in warm climates and warm weather than in cold; and we find the plants which furnish them grow in the greatest abundance in hot countries. The pepper tribe (*Piperaceæ*), for example, is confined to the hottest parts of the world, such as tropical America and the Indian Archipelago; forty species of pepper are met with in the island of Java alone. Throughout the East Indies the natives restore the powers of the stomach by chewing betel, which consists of slices of the areca nut, sprinkled with fresh lime, wrapped up along with some other aromatic in a leaf of the *piper betel*. The Indians of South America use the *Erythroxylum Peruvianum* (called *cocca*) along with the leaves of the *Chenopodium Quinoa*, mixed with quick-lime, to stimulate the impaired powers of the stomach during their long and toilsome journeys over the heights of the Andes. (See Humboldt, 'Tableau Physique de la Nouvelle Espagne.') On the same principle, the Europeans who visit tropical countries use curry and other hot dishes. But in every quarter of the globe we find condiments used along with all articles difficult of digestion, especially vegetables, fish, and young meats, such as veal. Aromatics are therefore employed both to prevent and cure diseased states of the stomach, and to assist the action of other remedies.

In simple loss of appetite, without any other obvious disease, or in slow digestion, they may be employed in the form of the warmer pickles during dinner, or preserved ginger after dinner.

In many cases of fever in warm climates, the stomach is so powerless that it cannot extract from cinchona bark, or other febrifuge medicines, the principles fitted to cure the disease, unless aided by aromatics. Hence, Cayenne pepper is added to them; and indeed Cayenne pepper will often cure the fever without any bark. Lately, piperin (the active principle of pepper) has been recommended as a means of curing fevers in Europe; and certain it is that some lingering fevers of the intermittent character, occurring in old or feeble persons, cannot be cured without the assistance of aromatics. [AGUE.] It may be stated however that piperin, when pure, has no aromatic property.

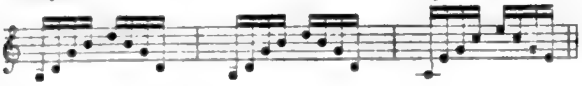
The preparation of iron (carbonate) which is found to be so useful in curing tic-douloureux, can rarely be borne by the stomach for such a length of time, or in such large doses, as are necessary, without adding aromatics to it. They are also very beneficially added to aloëtic purgatives, for the treatment of indigestion and constipation, occurring in literary and sedentary persons. Aromatics are frequently used to disguise the unpleasant taste of many medicines. The disagreeable taste of aloes is concealed by adding the aromatic or compound spirit of lavender, and the intensely bitter taste of the sulphate of quinia is nearly covered by mixing one part of it with ten or fifteen parts of powdered valerian, fennel, aniseed, or orange-peel.

Aromatics are most suited to persons of a phlegmatic constitution, or those advanced in life; less so to the young, or those of very irritable constitutions. They are to be altogether prohibited in certain states of the stomach or system generally. When there exists any inflammatory condition of the stomach they would be very improper; and it is necessary to observe, that in all degrees and stages of inflammation of the stomach, debility more or less is felt by the patient, which might seem to indicate their use; but under such circumstances they are extremely hurtful. The same observations apply to the aromatic teas, such as balm and sage, in common use among the people.

In certain affections of the brain, such as when there is a tendency to apoplexy, they are improper. Cullen mentions the case of a gentleman, who having taken by mistake two drachms of powdered nutmeg, in about an hour became drowsy, and fell from his chair. Being laid in bed, he dropped asleep, but awoke from time to time, and was quite delirious. He thus continued alternately sleeping and delirious for several hours. Even the following day he still complained of headache and drowsiness. In the East such cases are of frequent occurrence. Persons predisposed to affections of the brain should abstain from such articles, especially mulled wine at bed-time.

ARPEGGIO, in music (Ital. to play on the harp), is, when applied to keyed instruments, the striking the notes of a chord in rapid succession, as in the manner of touching the harp, instead of playing them simultaneously, the notes, when struck, being held out the full remainder of the time. Example—

On the violin, flute, &c., where the notes cannot be held out, the arpeggio is commonly executed thus:



ARQUEBUS. [Arms.]

ARRAC. [Arack.]

ARRAIGNMENT. This word is derived by Sir Matthew Hale from *arraisoner*, *ad rationem ponere*, to call to account or answer, which, in ancient law French, would be *ad-resoner*, or, abbreviated, *a-resner*. Conformably to this etymology, arraignment means nothing more than calling a person accused to the bar of a court of criminal judicature to answer formally to a charge made against him. The whole proceeding at present consists in calling upon the prisoner by his name, reading over to him the indictment upon which he is charged, and demanding of him whether he is guilty or not guilty. Until very lately, if the person accused pleaded that he was not guilty, he was asked how he would be tried; to which question the usual answer was, "By God and my country." This useless form was abolished by Stat. 7 & 8 Geo. IV., c. 28, s. 1, which enacts, that "if any person, not having privilege of peerage, being arraigned upon an indictment for treason, felony, or piracy, shall plead 'Not guilty,' he shall, without any further form, be deemed to have put himself upon the country for trial, and the court shall in the usual manner, order a jury for the trial of such person accordingly."

The arraignment of a prisoner is founded upon the plain principle of justice, that an accused person should be called upon for his answer to a charge before he is tried or punished for it. That this was a necessary form in English criminal law at a very early period appears from the reversal in parliament of the judgment given against the Mortimers in the reign of Edward II., which Sir Matthew Hale calls "an excellent record." One of the errors assigned in that judgment, and upon which its reversal was founded, was as follows: "that if in this realm any subject of the king hath offended against the king or any other person, by reason of which offence he may lose life or limb, and be thereupon brought before the justices for judgment, he ought to be called to account (*poni rationi*), and his answers to the charge to be heard before proceeding to judgment against him; whereas in this record and proceedings it is contained that the prisoners were adjudged to be drawn and hanged, without having been arraigned (*arrenati*) thereupon, or having an opportunity of answering to the charges made against them, contrary to the law and custom of this realm." (Hale's *Pleas of the Crown*, book ii. c. 28.

The ceremony of the prisoner holding up his hand upon arraignment is merely adopted for the purpose of pointing out to the court the person who is called upon to plead. As it is usual to place several prisoners at the bar at the same time, it is obviously a convenient mode of directing the eyes of the court to the individual who is addressed by the officer. In the case of Lord Stafford, who was tried for high treason in 1680, on the charge of being concerned in the Popish plot, the prisoner objected, in arrest of judgment, that he had not been called on to hold up his hand on his arraignment; but the judges declared the omission of this form to be no objection to the validity of the trial. (Howell's *State Trials*, vol. vii. p. 1555.)

ARREOY, a remarkable institution, which formerly subsisted in Otaheite and the other islands of the Society group. The first notice of the existence of this institution was brought to Europe by Cook, on his return from his first voyage in 1771. The account given in the narrative of the voyage published the following year was, however, generally supposed to have received a colouring from the florid pen of Hawkesworth, by whom the book was written. In the narrative of his second voyage, which he wrote himself, Cook appears inclined to soften down certain of the features of the former representation. Subsequent statements were given by Dr. Forster and others, for the most part differing from each other in important particulars. The fullest account, we believe, that has appeared, and at the same time the latest, is that given in Ellis's 'Polynesian Researches,' vol. i. pp. 311-344.

Amidst many contradictory statements, it seems to be admitted that the institution was distinguished by great profligacy of manners, and that infanticide was common with its members. One of the happy consequences of the introduction of Christianity into the island of Otaheite has been the entire abolition of those associations, as well as of the practice of infanticide generally. What effect this change may have upon the progress of population, remains in great part still to be ascertained. Mr. Ellis states, that when the missionaries arrived at the islands, the natural proportion of the sexes had been so deranged, that there were four or five men to one woman. Mr. Malthus has given it as his opinion, that the Arreoy was in all probability originally instituted with the view of preventing the inconvenient increase of population; and he seems to think that, from the unsparing rigour with which the fundamental law of the association appears to have been observed, it probably had that effect. But this opinion is in opposition to the general fact, which, as he notices, had been before remarked by Mr. Hume, that the existence in any country of a law permitting infanticide, had usually, from its tendency to promote marriages by diminishing the fear of their consequences, been attended with the opposite result.

ARREST is the apprehending or restraining a man's person by authority of law.

In criminal matters the object of an arrest is to secure the person of one who has, or is supposed to have, committed an offence, in order that he may be brought before a magistrate; and then, if there appears sufficient ground of suspicion against the party to justify his being put upon his trial, the magistrate takes measures for securing his presence before the proper court, either by committing him to prison, or by taking bail for his appearance.

An arrest may be made either by virtue of a warrant, or, where the law authorises it, without warrant. A warrant may be granted in extraordinary cases by the privy council, the secretaries of state, and some other public officers; but the only warrants which occur in the ordinary administration of the law are such as are issued by justices of the peace, whose duties in that respect are regulated by the statute 11 & 12 Vict. c. 42.

When a charge is made before a magistrate, it is his duty to examine the witnesses upon oath (unless it be intended to issue a summons, and not a warrant, in the first instance), and to take down their statement in writing; and then, if he see any probable ground of suspicion against the party charged, he may issue a warrant for his apprehension. The person to whom the warrant is directed—generally some constable or other peace-officer—is bound to execute it as far as the magistrate's jurisdiction and his own extends; but if the party to be arrested escapes into another county, the warrant cannot be executed without being *backed*, that is, signed by a justice of the peace for that county. [Warrant.]

But in many cases an arrest may be made without a warrant, particularly by officers connected with the administration of justice. A constable, for instance, may arrest in case of felony, if there is reasonable ground of suspicion, and for any breach of the peace actually committed in his view; so persons loitering at night, and suspected of having committed or being about to commit a felony, under the Act (9 & 10 Vict. c. 25) relating to injuries by explosive substances, may be arrested by any constable or peace-officer without a warrant.

An officer may, upon a criminal charge, break open doors, if, upon demand of admittance, it cannot be otherwise obtained; he may likewise, in apprehending a person charged with felony, use any degree of force that may be necessary; and if the person charged attempt to save himself by flight or resistance, and is killed by the officer (there being no other means of preventing an escape), the homicide is justifiable; but if he kill the officer with the intent to oppose him in the execution of his duty, it is murder.

Private persons, also, are not only authorised, but required, to apprehend any person who commits a felony in their presence; and in pursuing such felon, they will be justified in breaking open doors and in using force, as much as an officer. A private person may likewise arrest upon reasonable suspicion of felony; but inasmuch as this is not a duty enjoined by the law, he is not armed with the same privileges as where he saw the offence committed: he cannot justify breaking open doors, or using the same degree of force; if he kill the supposed offender, he will be guilty of manslaughter; and if he be killed, the offence will be the same, and not murder: besides this, he acts at his own peril, and is liable to an action unless he can show that a felony had been actually committed, and that there was reasonable ground to suspect the person whom he arrested.

There are also several cases where private persons have the power of arresting given them by Act of Parliament. Any person whatsoever is authorised to apprehend for any offence against the Vagrant Act, 4 & 5 Geo. IV. c. 83. And where persons are found committing any offence against the Larceny Act, or the Malicious Injuries Act, 7 & 8 Geo. IV. c. 29 and 30, they may be apprehended, without warrant, by any peace-officer, or by the owner of the property, or by his servant, or any person authorised by him. So any one may apprehend persons found committing offences under the Prevention of Offences Act, 14 & 15 Vict. c. 19, or persons found committing *any* indictable offence in the night.

When an officer has arrested any one, he ought to take him before a magistrate to be examined as soon as possible. Where a private person has made the arrest, he will in general be justified either in taking the party arrested before a justice of the peace, or delivering him over to a constable of the place, and this alternative is expressly given him by the Vagrant Act; but the Larceny Act and the Malicious Injuries Act require that the person arrested should be forthwith taken before a justice of the peace. But if a person be apprehended in an attempt to commit a felony at night, he may lawfully be detained, even by a private person, till he can be carried before a magistrate.

There is likewise another mode of arrest for felony, and that is upon *hue and cry* raised; but though this was once in ordinary practice, it has now fallen into disuse. [Hue and Cry.] Hale's 'Pleas of the Crown,' vol. i. p. 575, vol. ii. pp. 72-120; Stephen's 'Summary of the Criminal Law,' pp. 239-244.

Arrest in civil cases is of two kinds: 1, that which takes place before trial, and is called arrest on mesne process; 2, that which takes place after trial and judgment, and is called arrest on final process, or arrest in execution. [Process.]

The primary object of arrest on mesne process is to secure the defendant's appearance in court, so as to enable the plaintiff to proceed with his action against him. This compulsory mode of proceeding, being penal in its nature, was originally allowed by our law in such injuries only as are accompanied by force: its use, however, was gradually extended, partly by Acts of Parliament, partly by the fictitious proceedings of the courts, to almost every species of complaint; but by later regulations it has nearly been confined to cases of debt.

When it was intended to proceed by arrest, the plaintiff, after making an affidavit that the cause of action amounted to 20*l.*, which by stat. 7 & 8 Geo. IV. c. 71, was the lowest sum for which a party could be held to bail, commenced his action by suing out a writ, called a *capias*, directed to the sheriff, who, on its being delivered to him, granted a warrant to his inferior officers or bailiffs to execute it on the defendant.

With regard to arrest on mesne process, the law was materially altered by the statute 1 & 2 Vict. c. 110. Since that statute all personal actions must be commenced by writ of summons, and no defendant can be arrested before a judgment has been obtained against him, unless it be shown by the affidavit of the plaintiff, or of some other person, to the satisfaction of a judge of one of the superior courts, that such plaintiff has a cause of action against the defendant to the amount of 20*l.* or upwards, or has sustained damage to that amount, and that there is probable cause for believing that the defendant is about to quit England unless he be forthwith apprehended. The judge is then authorised to issue a writ of capias against such defendant; the proceedings upon such writ are the same as they were under the writ of capias, which formerly was used as the commencement of all personal actions which were commenced in the superior courts of common law, when the object was to arrest a person or hold him to bail. [Capias.]

This application to the judge may be made and the defendant arrested at any time after the commencement of the action, and before final judgment shall have been obtained therein. Upon making the arrest, the officer is required forthwith to deliver to the defendant a copy of the writ, and is not allowed to take him to gaol within twenty-four hours, unless, upon request made, he refuses to go to any place of safe custody. He is in general taken to the house of the officer (vulgarly called a 'spunging-house'), where (if not sooner lawfully discharged) he may be confined until the expiration of the eight days limited for the putting in of special bail.

When arrested, the defendant is in custody of the sheriff: but by stat. 43 Geo. III. c. 46, s. 2, he may obtain his discharge by depositing with the sheriff or his officer the sum for which he was ordered to be held to bail, together with 10*l.* to answer for the costs, or by giving bail for his appearance to defend the action: this being what most commonly occurs, the process upon which an arrest is founded is called *bailable* process. For further information on this subject, see Bail.

The Commissioners of the district Courts of Bankruptcy and the Judges of the County Courts have now power, by the Absconding Debtors' Arrest Act, 1851, to grant a warrant for the arrest of absconding debtors, and for their detention for seven days, until a writ of *capias* can be procured from one of the superior courts of law. By this means debtors absconding from the seaports at a distance from London may be arrested on the spot, and detained until they pay the debt or give bail to the action, or deposit the money in the hands of the sheriff.

Arrest on final process, or arrest in execution, is one of the means by which a party who has succeeded in an action may compel performance of the judgment.

Arrest in execution may in general be resorted to in any case where, before trial, bailable process might issue; when execution has been taken out against the property, and there is not enough to satisfy the judgment, execution against the person may afterwards be resorted to; but if the person has once been taken in execution, no process can in his lifetime issue afterwards against the property. [Execution.]

The statute 7 & 8 Vict. c. 96 has, however, effected a very important alteration in arrest on final process or in execution. The 57th section enacts that no person shall be taken or charged in execution upon any judgment obtained in any of Her Majesty's superior courts, or in any county court, court of requests, or other inferior court, in any action for the recovery of any debt wherein the sum recovered shall not exceed the sum of 20*l.* exclusive of the costs recovered by such judgment.

An arrest is made by seizing or touching the defendant's person. The officer is not justified in breaking open the defendant's house in order to arrest him; but, when once the arrest is made, he may break into any house in pursuit of him.

Certain personages were from the earliest times privileged from arrest or civil process, either entirely so, or temporarily. A list of them is given in Blackstone's 'Comm.,' Mr. Kerr's edit., vol. iii. p. 298, &c.

In France, imprisonment seems to have existed from the earliest ages as a means of execution to compel the payment of a debt, though its application was originally restricted to cases where the property of the debtor had been previously seized and found insufficient. In the reign of Louis XIV. a principle was introduced, which at the present day constitutes one of the characteristics of French jurisprudence; debts of a commercial nature being distinguished from debts purely civil, and arrest being allowed as of course in the former, but, in the latter, only in a few specified cases.

An arrest, by the law of France, cannot take place without being authorised by the sentence of a court. The cases in which this authority is exercised in matters not of a criminal nature may be classed under four heads:

I. In all cases of commercial debt to the amount of 200 francs (8*l.* sterling), arrest forms part of the sentence as a matter of course. The object of imprisonment is to compel the debtor to give up any property which he may be supposed to have concealed; after a certain length of confinement, it may be presumed that, if he has given nothing up, it was because he had nothing to give; and thus the reason for detaining him ceases to operate. The debtor is, therefore, in all cases discharged from prison, after a certain length of time, varying according to the amount of the debt. In commercial cases, the length of imprisonment varies from one year to five.

II. In actions of a purely civil nature, arrest takes place only in those cases which are specified by the laws. The civil code (Arts. 2059, 2060) contains an enumeration of the cases in which it is pronounced as a matter of course. They are chiefly such as imply either gross fraud, or a breach of official duty. The length of imprisonment varies from one year to ten.

There are other cases in which the court have a discretionary power to pronounce sentence of imprisonment if they think fit; the length of confinement varies in this instance from one year to five. In all civil cases, 300 francs, or 12*l.* sterling, is the lowest sum for which a person can be arrested.

III. All public servants are liable to arrest in respect of any sum of money to the amount of 300 francs, 12*l.* sterling, due, by virtue of their office to the state, or any public establishment. The duration of imprisonment varies from one year to ten.

IV. With respect to foreigners not domiciled in France the law is peculiarly severe. As their property is presumed to be in their own country, the confinement of their persons is considered to be the only means by which they can be compelled to satisfy their creditors; they are, therefore, liable to arrest for all debts, whether civil or commercial, provided the sum amounts to 150 francs, or 6*l.* sterling. And for this sum a foreigner may be arrested, not only after final judgment, but as soon as the cause of action has arisen. In the latter case, however, he may obtain his discharge by finding sureties, or by proving that he is possessed of sufficient property in France to pay the debt: when arrested on final judgment, the duration of his imprisonment varies from two years to ten.

A debtor who has entered his 70th year cannot be arrested on final process, except in the case *stellionat*, the *stellionatus* of the Roman law, a fraud committed by a party in falsely representing property as being his own or as being free from incumbrance. And with the same exception, a debtor who is in prison is, on entering his 70th year, entitled to be discharged. The debtor likewise obtains his discharge in the following cases:—1. If the creditor give his consent thereto; or 2. If he neglect to advance the sum which the law requires him to pay for the support of the debtor. This sum is now fixed at 25 francs, 1*l.* sterling per month, except in Paris, where it is 30 francs; 3. By payment of the debt, costs and expenses; or, in cases not commercial, by payment of one-third thereof, and finding sureties for the remainder; or 4. By being allowed the benefit of cession, answering to a discharge under the Insolvent Act in English Law. [Cessio Bonorum.]

(See *Code Civile*, Arts. 2059-2070; *Code de Procédure Civile*, Arts. 780-805; law of 17th of April, 1832; Fœlix, *Commentaire sur la Contrainte par Corps.*)

ARREST OF JUDGMENT. After an action at law has been carried through all the stages previous to the judgment, and the plaintiff has up to this point been successful, the defendant may still move in arrest of judgment: that is, he may pray the court to withhold or arrest the judgment to which the plaintiff is apparently entitled, on the ground that there is some error appearing on the face of the record, which vitiates the proceedings. In consequence of such error, on whatever part of the record it may arise, the court is bound to arrest the judgment, but the error must be such as is apparent on the record, and generally speaking, it must not be an error in a mere point of form. This was formerly otherwise [Amendment]; but at the present day judgment cannot be arrested for any merely formal objection.

For further information on this matter, see Blackstone's *Comm.*, Mr. Kerr's ed., vol. iii. ch. 24; Comyn's *Dig.*, tit. "Pleader," § 48.

ARRESTMENT in the law of Scotland is a process by which a creditor may attach money or moveable property which a third party holds for behoof of his debtor. It bears a general resemblance to the custom of foreign attachment in the Mayor's Court of the City of

London. [Attachment, Foreign.] The person who uses it is called the arrestor; he in whose hands it is used is called the arrestee, and the debtor is called the common debtor. It is of two kinds, arrestment in execution and arrestment in security. The former can proceed only on the decree of a court, on a deed which contains a clause of registration for execution, or on one of those documents, such as bills of exchange and promissory notes, which by the practice of Scotland are placed in the same position as deeds having a clause of registration. Arrestment in security is generally an incidental procedure in an action for the constitution of a debt; but it may be obtained on cause shown, as a method of constituting a security for a debt not yet due. This latter class of arrestments is under the equitable control of the judge who issues it; and it is a general principle that it cannot be obtained unless the claimant show that circumstances have occurred which have a tendency to make his chance of payment less than it was at the time when he entered into the engagement with his debtor. An arrestment may be recalled on it being shown that it should not have been issued, and an arrestment in security may be "loosed" on the debtor finding security for the payment of his debt. An arrestment in execution expires on the lapse of three years from the date of its execution, and an arrestment in security, on the lapse of three years from the day when the debt becomes due. In the meantime, the person in whose hands the process is used, is liable in damages if he part with the property arrested, but it cannot be attached after he has parted with it, in the hands of a *bonâ fide* holder. The arrestment is made effectual for the payment of the debt by an action of Forthcoming, in which the common debtor is cited. It concludes for payment of the money if the arrestment be laid on money, or for their sale for behoof of the creditor, if it be laid on other moveable goods. The arrestee may plead against the arrestor whatever defence he might have had against the common debtor.

There is another species of arrestment, called arrestment *jurisdictionis fundandæ causâ*, the object of which is, by attaching the moveable property of a defendant who is not in Scotland, to give jurisdiction to the Court of Session to proceed against him. This arrestment may be loosed, as in other cases, on security being given by the arrestee to abide the judgment of the court. (London and N. W. Rail. Co. *v.* Lindsay, 3 Macqueen's Reports, p. 99.)

ARRIS, in French *Areste* and *Arête*, is a term employed in building. It may be defined as the intersection or line in which the two straight or curved surfaces of a body, forming an exterior angle, meet each other. The term arris, synonymous with edge, is constantly employed by workmen engaged in buildings, especially in the formation of mouldings, whether of stone, wood, or plaster. In parallelopipedal bodies, on which the length and thickness may be measured, as in planks, bond timbers, shutters, &c., the term edge only is used. In Gothic architecture, owing to the numerous lines and angles, the arris is of frequent occurrence; for example, in the mullions and transoms of windows, where there are many mouldings, every edge is an arris, whether formed by square mouldings or by the intersection of curves. In Grecian architecture, the raised edge between two flutes of a Doric column, and in both Grecian and Roman architecture, the lines bounding every flat moulding are so many examples of the arris.

ARRIS FILLET, a small triangular piece of wood, used to raise the slates of a roof against the shaft of a chimney or a wall, to throw off the rain more effectually; it is used for the same purpose also in forming gutters round skylights, which have the same inclination as the roof, and are slightly raised above it.

ARROW-HEADED CHARACTERS. [Cuneiform Inscriptions.]

ARROW-ROOT. An article of commerce, which is imported in considerable quantities from both the West and East Indies. It is a farinaceous substance, prepared from the roots of certain plants. That which is brought from America is made from the root of the *Maranta Arundinacea;* the arrow-root imported from Asia is extracted from the tubers of the *Curcuma Angustifolia.* [For the botanical descriptions of these plants, see Maranta and Curcuma, in Nat. Hist. Div.]

The English name of this preparation is derived from the use to which the Indians of South America were accustomed to apply the juice extracted from another species of *Maranta*—the *Maranta galanga,* which was employed as an antidote to the poison in which the arrows of hostile tribes were dipped.

The method of preparing the arrow-root of commerce is the same from whichever of the two plants it is extracted. The root, or tuber, as the case may be, must first be carefully washed, in order to remove the adhering particles of earth, and then it is either grated or beaten to a pulpy consistence in a mortar, which should be formed of wood. The pulp is next intimately mixed with a considerable quantity of pure water, by which operation the fibrous portion is separated from the farina, which remains mechanically suspended in the water. This fibrous portion is then removed, the larger parts by the hand and the minuter parts by straining through a hair sieve. The remaining milk-like fluid is then left for subsidence, after which the water is drawn off. A second and sometimes a third washing in fresh water and straining through finer sieves of the pulpy residuum, are then employed; after which the starchy matter is collected in a state of purity, and its moisture thoroughly evaporated by exposure to the sun and air. When perfectly dry it is packed in casks or boxes, and will retain its nourishing property unimpaired for many years.

Arrow-root may be used with advantage as the food of young children or of persons in delicate health, since its nutritive property is great, and it is of very easy digestion. It is used either mixed with hot water or boiling milk, or in the form of puddings. The powder is frequently adulterated by the admixture of common starch or the farina of potatoes, and it is therefore advisable to purchase it in the package in which it is imported, or from some dealer of respectability. That which is the most esteemed for purity is imported from the Bermudas and New Providence; but within the last few years the arrow-root of Ceylon has acquired some celebrity: this is made from the American plant the *Maranta Arundinacea,* which was conveyed from the West Indies to Ceylon. The cultivation has lately been introduced with considerable success into the island of St. Vincent; machinery of skilful construction is employed to prepare the arrow-root from the plant; and the packing for shipment is carefully conducted.

ARSENAL, from the Italian *Arsenale,* a magazine of warlike stores, or government establishment, where naval and military arms, ammunition, and equipments, are manufactured and stored. Portsmouth, Plymouth, Woolwich, Deptford, Sheerness, and Pembroke, are the principal English naval arsenals: Brest, Toulon, L'Orient, and Cherbourg, the principal French ones. Paris, Vincennes, Vernon, and Metz, are some of the French military arsenals, whilst, besides the Tower, which is principally a store, Woolwich is the only English military arsenal.

Woolwich arsenal contains a brass-gun foundry, where all the brass guns and fitments used in the British service are cast, to which latterly an iron foundry has been added, where a few iron guns, shot, and shell are cast, principally to act as a check on the private foundries which supply most of them. Besides these Woolwich arsenal contains the following departments: boring department, both for brass and iron guns; carriage department, for the manufacture of gun-carriages, limbers, waggons, and the various carriages and equipments of an army; laboratory, containing percussion-cap factory, rocket manufactory (both Congreve and signal), workshops for the manufacture and filling of shells and fuzees, the compression of lead bullets, and the making-up and packing of all descriptions of ammunition; proof department, for proving brass and iron guns, shot, and shell; and lastly, a store department for warehousing all descriptions of military equipment. The greater portion of the gunpowder used in the British army is made at the government powder-mills at Waltham Abbey. A manufactory for small arms has also, within the last few years, been established at Enfield, from which the rifle now used in the army takes its name. These are afterwards proved at the Tower.

At the naval arsenals men-of-war are, when put in commission, fitted out and equipped for sea, and when paid off, stripped and laid up in ordinary. [Dockyard.]

ARSENIATES. [Arsenic.]

ARSENIC. (As). The term Arsenic is derived from the Greek *ἀρσενικὸν*, which is found first in the works of Dioscorides, and of some other authors who wrote about the beginning of the Christian æra. It denotes, in their works, the substance called *σανδαράκη* by Aristotle, and *αρσενικόν* by Theophrastus (although Pliny, lib. xxxiv. 18, seems to make a distinction between *σανδαράκη* and *ἀρσενικὸν*), and is said to be the *auri pigmentum,* the well-known paint, orpiment.

Arsenic is a peculiar metal, which, though long known, was first examined with tolerable precision by Brandt, in 1733. It is very frequently met with in nature; sometimes in its pure metallic state, but more commonly combined with other metals, as nickel, cobalt, and iron, or with sulphur, and sometimes united with oxygen. It may be artificially obtained from its natural compounds in a mode which will be presently pointed out.

Arsenic has a steel gray colour and considerable brilliancy; its density is 5·700 according to Berzelius, and 5·884 by Turner's experiments; when sublimed, Dr. Thomson states that its density is only 5·235; the native metal is granular, and the artificial crystalline; it is extremely brittle, and consequently easily powdered. When arsenic is exposed to the air it soon loses its lustre, and becomes black on the surface; the artificially obtained metal not only suffers these changes, but falls to powder by the action of the air: in this state it is known on the continent by the name of *fly-powder,* and is supposed by Berzelius to be a peculiar oxide of arsenic; most chemists, however, regard it as a mere mixture of arsenious acid and the metal. When kept under water, arsenic is gradually converted into arsenious acid; if heated to 356° Fahrenheit, it is volatilised, without previous fusion; the vapour has a strong smell, resembling that of garlic, and this, to a certain extent, is relied upon as proof of its presence; the vapour readily condenses in small brilliant crystals of metallic arsenic, the form of which is an acute truncated rhombohedron. According to Berzelius, arsenic exists in two allotropic conditions; one is of a dark gray colour, and soon falls to powder in the air; the other is nearly white, with a strong metallic lustre, and is permanent in the air.

Arsenic and oxygen combine in two proportions, and both compounds possess acid properties.

Arsenious acid (AsO_3). As a natural product, arsenious acid is extremely rare; it may be artificially prepared by heating the metal in atmospheric air, when, being very combustible, it burns and combines with oxygen; the white vapour of arsenious acid formed, speedily condenses, and frequently in the form of the regular octahedron; this acid may also be procured by heating the metal in very dilute nitric acid, which being decomposed yields oxygen. These processes are, however, needless, for arsenious acid is met with abundantly, and very pure, as an article of commerce; being formed and volatilised during the roasting of cobalt ores, it is first condensed in an impure state, and purified by a second sublimation in an iron vessel. Arsenious acid (oxide of arsenic, the white arsenic of the shops, and of the 'London Pharmacopœia'), has the following properties: it occurs in compact masses of various sizes, which are externally colourless and opaque, but internally, when recently broken, frequently yellowish and transparent, and of a glassy appearance and fracture; by exposure to the air the transparency is lost; the density of the opaque kind is 3·706, and that of the glassy 3·699. Arsenious acid is volatilised at 380° Fahrenheit; the vapour has not the garlic smell, like that of metallic arsenic. According to Dr. Christison, arsenious acid has little or no taste. It is well known as a most virulent poison. Arsenious acid is soluble in water; at about 60° Fahrenheit it dissolves about 1-50th of its weight, and when boiling, nearly 1-13th; on cooling to 60°, a considerable portion is deposited in octahedral crystals, so that only about 3-8ths of that taken up remains dissolved; the solution reddens litmus paper but slightly, and though it acts feebly as an acid in this respect, and does not decompose the alkaline carbonates when cold, yet it expels their carbonic acid when they are heated together in solution. The nature of the saline compounds will be presently mentioned.

In order to avoid the danger of accidentally poisoning by arsenic, or any colourless preparation of arsenic, and to render its use more difficult for intentional poisoning, an Act was passed regulating the sale of such substances, in the session of parliament 1851. By this Act it is required that, except when sold for agricultural or other purposes in quantities of not less than ten pounds, or to be used in medicine by a qualified practitioner, all arsenious acid is to be mixed and coloured with soot or indigo; that all persons selling arsenic are to keep a book in which the name, place of abode, condition or occupation of the purchaser, the quantity sold, and the purpose for which it is required, shall be entered, certified by the signatures of the seller and the purchaser, or the referee of the purchaser, whenever he is not personally known to the seller. Any infraction of these provisions subjects the offender to penalties not exceeding 20*l.* for each offence, to be levied by two justices on summary conviction.

Arsenic acid (AsO_5) exists in nature much more commonly than the arsenious acid; sometimes it is found combined with lime, and frequently with various metallic oxides, as those of copper, iron, and lead; the arseniates of copper constitute, indeed, a most beautiful and extensive variety of the ores of that metal.

Arsenic acid may be formed artificially by heating either the metal or arsenious acid in nitric acid, or, which is preferred, in a mixture of nitric and hydrochloric acid; the mixture is to be distilled in a glass retort until it has acquired the consistence of a syrup; afterwards it is to be heated nearly to redness in a platina crucible, until all the nitric acid is expelled. Arsenic acid thus prepared is of a milk-white colour; it contains no water, but when exposed to the air attracts moisture until a solution of specific gravity 1·935 is obtained; when water is added to the anhydrous acid it dissolves only a part of it for a long time, leaving a white powder, which is, however, eventually taken up; by evaporation a syrupy liquid of specific gravity 2·55 is obtained, which, when concentrated till the temperature rises to 248°, begins to deposit solid matter. The anhydrous acid has not a very strong taste, but the aqueous solution is extremely sour, acts strongly as an acid on litmus paper, and decomposes alkaline carbonates when cold. It is extremely poisonous. Its salts, termed arseniates, will be mentioned hereafter.

Arsenuretted hydrogen (AsH_3)—Arsenic is one of the few metals which form permanent compounds with hydrogen. Arsenuretted hydrogen may be prepared by fusing equal weights of arsenic and zinc, and dissolving the alloy in hydrochloric acid; the gas may be received in air jars filled with and inverted in water, in which it is insoluble. This compound is gaseous at the usual temperature of the air,: but when subjected to intense cold, it is condensed into a limpid liquid resembling ether. The gas has an extremely fetid smell; its specific gravity is 2·695; it is fatal to animals when it forms only 1-10th of the air which they breathe. When exposed to atmospheric air, it is decomposed; metallic arsenic, mixed with some arsenious acid, is deposited, and water is formed. It is composed of 6 volumes of hydrogen gas, and 1 of the vapour of arsenic, condensed into 4 volumes.

There is also a solid compound of arsenic and hydrogen; it is obtained by employing arsenic as the negative electrode, when water is decomposed by electricity; the hydrogen of the water, instead of being evolved, combines with the arsenic, and the compound is detached from the metal in brown-coloured flocks. Its composition has not been clearly ascertained.

Terchloride of arsenic ($AsCl_3$).—When arsenic in powder is thrown into chlorine gas, it burns, owing to the heat attending the combination; when also a mixture of 1 part of arsenic and 6 parts of perchloride of mercury is distilled, a fuming colourless liquid condenses in the receiver; the product in both cases is terchloride of arsenic. It is very volatile, and does not become solid at a low temperature. If water and chloride of arsenic are mixed, both are decomposed, and arsenious and hydrochloric acids are formed. When heated, chloride of arsenic dissolves sulphur and phosphorus, but they separate on cooling.

Another method of preparing chloride of arsenic is, to put 1 part of arsenious acid and 12 parts of sulphuric acid into a retort, heat the mixture nearly to 212°, and then gradually add small fragments of fused common salt; pure chloride of arsenic, which is to be condensed by artificial cold, passes over into the receiver. A little water frequently comes over with the chloride towards the end of the operation, and this hydrated chloride does not mix with, but floats on, the anhydrous chloride first distilled.

Arsenic does not appear to unite with carbon; it combines with bromine, iodine, fluorine, selenium, and phosphorus; but the resulting compounds are not important.

Compounds of sulphur and arsenic.—Arsenic and sulphur may be made to combine in several different proportions; two of these sulphurets, and the more important, exist in nature, and these only will be described at any length. The first is the red sulphuret of arsenic, commonly called *realger* (AsS_2); this is found native in several parts of Europe, and sometimes crystallised. It is of a deep-red colour, brittle, easily reduced to powder, inodorous, tasteless, and insoluble in water: its specific gravity is about 3·338. It may be artificially formed by melting a mixture of arsenic and sulphur in a covered crucible, or the arsenious or arsenic acid may be used. In the latter cases, sulphurous acid is formed and evolved, owing to the oxygen of the acid combining with a portion of the sulphur. In close vessels, it sublimes unchanged. It appears to be poisonous, but less so than arsenious acid. It is used as a pigment.

The second is the yellow sulphuret of arsenic (*Sulpharsenious acid*, AsS_3) usually called *orpiment*. This sulphuret is also a natural product, occurring rarely crystallised: it is commonly composed of thin plates, which are of a very fine yellow colour, and flexible to a considerable degree: its specific gravity is 3·452. It is insoluble in water, and inodorous. Acids do not dissolve it, but nitric acid and chlorine decompose it. When heated in close vessels, it melts, and then sublimes; when heated in the air, it burns with a pale blue flame, and gives a white vapour, and an odour of sulphurous acid. It may be formed artificially by passing a current of sulphuretted hydrogen gas into an acid solution of arsenious acid. It is used as a pigment, and is the colouring ingredient of *king's yellow.*

The other sulphurets of arsenic are unimportant.

Arsenic and metals in general combine with great facility: those which are malleable it renders brittle, and those which are difficult to melt, it renders fusible.

The combination of arsenic with potassium and sodium is attended with the disengagement of much heat. The resulting arseniurets are decomposed by water, the potassium and sodium are oxidised, while the hydrogen of the water converts the arsenic partly into gaseous arsenuretted hydrogen, and partly into the brown arseniuret of hydrogen already noticed.

The metallic arseniurets are not of sufficient importance to require a more minute description.

We have now to notice the salts that contain the arsenious and arsenic acid, and which are termed respectively *arsenites* and *arseniates.*

Arsenite of ammonia (NH_4OAsO_3) may be prepared by dissolving arsenious acid in solution of ammonia. It cannot be obtained in a solid form, for by evaporation the salt is decomposed, ammonia is evolved, and octahedral crystals are obtained, which are mere arsenious acid without a trace of ammonia.

Arsenite of potash ($2KO,AsO_3$) is procured by digesting the acid in a solution of the alkali. By evaporation, a saline mass is left, but no crystals of the salt are formed. This compound is employed in the preparation of arsenite of copper, sometimes called *Scheele's green.* It is also the basis of the *liquor arsenicalis* of the 'London Pharmacopœia Two other arsenites of potash have also been formed.

Arsenite of soda ($2NaO,AsO_3$) is prepared as the last mentioned. By evaporation, a viscid mass is obtained; and when the evaporation has been continued till the solution has acquired the consistence of a syrup, small granular crystals are obtained as it cools. Two other arsenites of soda are also known.

Arsenite of lime ($2CaO, AsO_3$) may be readily procured by mixing an aqueous solution of the acid with lime water; the arsenite being nearly insoluble in water, is precipitated in the state of a white powder: it contains water, is soluble in acids, and even in some saline solutions. It is poisonous.

Arsenite of baryta ($2BaO, AsO_3$) is a white powder, slightly soluble in water.

Arsenite of strontia ($2SrO, AsO_3$) is soluble in water.

Arsenite of copper (CuO, AsO_3 ?).This compound was first prepared by Scheele, and by him proposed as a pigment; and it has been long and extensively used as such, under the name of *Scheele's green.* It is formed by adding a solution of arsenite of potash to one of sulphate of copper (blue vitriol). By double decomposition, arsenite of copper is formed, and is precipitated of a fine green colour. The exact composition has not been determined: indeed, it is probable that more than one compound may be formed, or one may be mixed with variable quantities of hydrate of copper.

Arsenite of silver ($3AgO, AsO_3$) may be made by mixing a solution of nitrate of silver with one of arsenite of ammonia, potash, or soda. It is of a fine yellow colour; and the soluble salts of silver, like those of copper, are occasionally used to afford corroborative evidence in cases of poisoning by arsenic.

The *arseniates* are in several cases presented to us by nature. Thus, in Cornwall, arseniate of iron occurs in small green cubic crystals, and also several beautiful varieties of arseniate of copper. Arseniate of lime, called pharmacolite by mineralogists, is sometimes, though rarely, met with.

The alkaline and earthy arseniates are generally procured either by direct combination or by double decomposition; and the metallic arseniates usually, if not always, by the latter method. We shall describe the arseniates in the same order as the arsenites.

Arseniate of ammonia ($2NH_4O, HO, AsO_5$).—This salt is prepared by adding the alkali to a rather concentrated solution of the acid, until a precipitate appears. If this and the solution be exposed to spontaneous evaporation, large rhombic crystals are obtained. These crystals, when exposed to the air, lose half of their base, and are converted into *mono-arseniate of ammonia*. When subjected to distillation, the arseniate of ammonia decomposes as it becomes dry, ammonia, water, and nitrogen gas are obtained, and the arsenic is reduced.

The *mono-arseniate of ammonia* ($NH_4O, 2HO, AsO_5$) may not only be obtained, as above-mentioned, by exposing the neutral salt to the air, but also by adding arsenic acid to it. By slow evaporation, large octahedral crystals are formed: when heated, it yields arsenious acid, but no ammonia.

Tri-arseniate of potash ($3KO, AsO_5$).—It may be procured by saturating the acid with the alkali. It is an uncrystallisable deliquescent mass, and may also be obtained by fusing a mixture of arsenious acid and hydrate of potash. The arsenious acid acquires oxygen from the decomposed water, hydrogen gas being evolved, and sometimes a portion of the arsenious acid is reduced.

Mono-arseniate of potash (KO, AsO_5) is usually prepared by heating a mixture of arsenious acid and nitrate of potash. The nitric acid yields oxygen to the arsenious, so as to convert it into arsenic acid, which uniting with the potash, the mono-arseniate is formed. The mass, when dissolved in hot water, yields transparent crystals of the salt. The solution reddens litmus paper. The salt suffers no change by exposure to the air: its taste is cooling and saline, somewhat like that of nitrate of potash. The crystals contain water.

The *arseniate* and *mono-arseniate of soda* are crystallisable salts, but which do not require any particular notice. The *arseniates* of the earths are not of importance.

Arseniate of baryta and *arseniate of strontia* are both soluble salts: they are entirely artificial compounds, and applied to no use. With respect to the metallic arseniates, we have already stated that the arseniates of iron and copper occur in Cornwall: they may also be formed artificially. The *arseniate of silver* is of a brick-red colour, while, as already noticed, the *arsenite* is yellow. Some use is made of this difference in processes for detecting the presence of arsenic. Most metallic arseniates are insoluble in water, but dissolved by acids. As to the general properties of arsenical acids and salts, we shall merely remark that both the acids are precipitated yellow by sulphuretted hydrogen; the arsenites are precipitated yellow by the salts of silver, and green by those of copper; while the arseniates are thrown down red by the silver salts, and blue by the copper ones.

ARSENIC, DETECTION OF. Of all substances, arsenic is that which has most frequently occasioned death by poisoning, both by accident and design; we shall therefore briefly state the methods of ascertaining its presence.

Supposing a white powder to have been found under suspicious circumstances, the process to which it is to be subjected is that of reduction to the metallic state and sublimation, and for this purpose we employ a small glass tube, a spirit lamp and black flux, or fresh burnt and powdered charcoal. The tube should be thin, closed at one end, about one-fourth of an inch in diameter, and three to four inches long; those known by the name of *test tubes* answer the purpose extremely well. Black flux is a mixture of charcoal and carbonate of potash, prepared by deflagrating two parts of bitartrate of potash and one part of nitrate in a crucible. It is to be powdered, and immediately put into a well-stopped bottle to prevent its acquiring moisture from the air; the charcoal which it contains is derived from the decomposition of the tartaric acid, and the potash from that of the bitartrate and nitrate. Mix a small portion, a grain or two, or even less, of the suspected powder with twice its quantity of the black flux, and convey the mixture to the bottom of the tube by means of a trough of smooth writing paper, taking care that none remain adhering to the sides of the tube. Put a paper plug loosely into the orifice of the tube, and twist a piece of paper round the upper end of it, to serve as a handle; then expose the mixture to the flame of the spirit lamp. The potash of the flux retains the arsenious acid until it is sufficiently heated to be decomposed by the charcoal. If the quantity of arsenious acid be extremely small, then it is better to drop it into the tube, and to let fall a little powdered charcoal upon it. In a very short time after applying heat as before, the charcoal combining with the oxygen of the arsenious acid, the reduced metal rises in vapour, and condenses in the upper and cool part of the tube; it has a metallic appearance, and is of a brilliant dark steel-gray colour.

Although this effect may be regarded as evidence of the presence of arsenic, Dr. Turner has improved upon it by showing that the metal may be easily re-converted to arsenious acid, and exhibit the characteristic form and properties of that substance, although its weight may not exceed one-hundredth of a grain. This change is effected by holding that part of the tube which contains the arsenic about three-fourths of an inch above a very small flame of the spirit lamp; the metal again sublimes, and re-combining with the oxygen of the air in the tube, forms well-defined crystals of arsenious acid.

If no solid arsenious acid should be found, but is suspected to exist in solution, either in the food or in the contents of the stomach, then these materials, after being boiled with dilute hydrochloric acid, and strained through calico, should be tested by one or more of the following processes.

Reinsch's test.—Boil a portion of the strained liquid, obtained as just mentioned, with bright copper turnings or strips of copper foil, for half an hour. If the surface of the copper become dull during this operation, the fragments must be carefully washed with distilled water, dried at 212°, introduced into a clean and narrow glass tube, and then heated nearly to redness. If a sublimate condense on the cooler portion of the tube, it must consist either of arsenious acid or metallic mercury; the beautiful transparent octahedral crystals of the former cannot, however, be confounded with the brilliant metallic globules of the latter.

Marsh's Test.—This invaluable process for the detection of arsenic depends upon the formation of arsenuretted hydrogen, when any solution containing arsenic is brought into contact with nascent hydrogen. To apply it, the strained liquid above mentioned is introduced, together with a few strips of zinc, into the apparatus figured in the margin, the zinc being placed in the lower bulb. If the liquid be not already sufficiently acid to act readily upon the metal, it may be rendered so by adding either hydrochloric or sulphuric acid. On then inserting the cork and closed stopcock, the gas evolved gradually collects in the lower bulb, expelling the liquid into the upper one, until the zinc is left above the liquid, when further action of course ceases. On now cautiously opening the stopcock, the gas, which will be expelled by the pressure of the column of liquid, must be ignited, and the flame made to impinge upon the interior of a small porcelain cup or basin. The production of a brown or black stain upon that part of the porcelain upon which the flame has played, proves the presence of arsenic or antimony. If now a small quantity of solution of chloride of lime (bleaching-powder) be poured into the porcelain cup so as to cover the stain, the latter will disappear if it consist of arsenic. If the stain do not disappear, antimony is present; but the stain may also have contained arsenic, as it is impossible to perceive with certainty, whether or not a *portion* only of the stain has dissolved. Under these circumstances, to ascertain indubitably the presence of arsenic, recourse must be had to Fleitman's test, which must be applied to another portion of the original strained acid liquor.

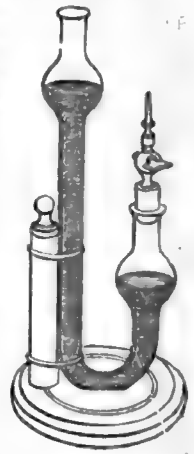


Fig. a.

Fleitman's Test. — This simple and very valuable test is founded upon the circumstance that when an arsenical solution is heated with excess of caustic soda or potash, in contact with zinc, arsenuretted hydrogen is evolved; whilst by a similar treatment of an antimonial solution, no antimonuretted hydrogen is liberated. It therefore affords a ready means of detecting arsenic with certainty, even in presence of antimony.

The following is the method of applying this test. A portion of the strained liquid above alluded to is placed in a test-tube, *Fig. a*, containing a few fragments of granulated zinc. A strong solution of caustic soda or of caustic potash is then added until the liquid is strongly alkaline, and the mouth of the tube being closed by a strip of filter paper, moistened with solution of nitrate of silver, the heat of a spirit lamp is applied to the liquid in the tube until gentle ebullition commences, care being taken to hold the tube in an inclined position, so as to prevent the contents from spirting upon the paper. If arsenic be present, the paper impregnated with silver solution will become tinged of a more or less deep brown colour; any such alteration in the colour of the paper is a positive proof of the presence of arsenic. The coloration of the paper is produced by the decomposition of arsenuretted hydrogen and the formation of brownish black arsenide of silver.

There are many other tests for the detection of arsenic, but the foregoing having been selected as the best and most conclusive, it is unnecessary here to allude to them.

It is of course necessary that all the chemicals used in the above tests should be first proved to be perfectly free from arsenic, by the application of the tests themselves. Zinc, sulphuric acid, and especially hydrochloric acid, even when the latter is sold as *pure*, are not unfrequently contaminated with arsenic.

ARSENIC, *Medical Properties of*. As metallic arsenic has no effect upon the human system, we shall mostly confine our observations to the employment and mode of action of the white oxide or arsenious acid, and its compound, the arsenite of potash. The characters of arsenious acid have been given above, but one remarkable circumstance connected with these requires to be noticed here; the degree of solubility depends on the degree of transparency or opacity of the specimen or portion employed. For example, 1000 parts of boiling water dissolve 97 parts of the transparent acid, retaining only 18 parts when cold; but an equal quantity of water will dissolve 115 parts of the opaque variety, and retain 29 parts when cold, the remaining parts being precipitated. It is manifest, therefore, that the strength of a solution must vary with the kind of specimen employed. This discrepancy is denied by Dr. Alfred Taylor. ('Guy's Hosp. Reports,' vol. iv .p. 83.) The precise character of the taste of white arsenic is a matter of dispute; it is generally said to be acrid and corrosive, followed by an impression of sweetness; but Dr. Gordon states, that it is *at first* always sweet, but afterwards somewhat acid. (Gordon, 'Dissert. Inaug. de Arsenico,' Edinb. 1814, p. 9; 'Edinburgh Medical and Surgical Journal,' vol. xi. p. 134.)

The white oxide of arsenic being so often employed for the destruction of human life, a dread of it exists, not only among the unprofessional part of the community, but even among medical men, which has caused it to be less tried, and its modes of action less studied, than most other medicinal agents of the *Materia Medica*. That it labours under a most unjust opprobrium cannot be doubted, for it is not so poisonous as many other articles frequently used, such as prussic acid and strychnia, while its curative influence is certainly very great.

If a small quantity of the white oxide of arsenic, such as $\frac{1}{30}$th or $\frac{1}{16}$th of a grain be swallowed, in about a quarter of an hour the individual experiences an agreeable sensation of comfort and warmth about the stomach, which gradually extends itself over the whole of the abdomen. The appetite and thirst are moderately increased, the secretion of urine becomes more abundant, and the evacuations from the intestines often more frequent, and of a pulpy or pappy character. From the intestinal canal the peculiar action propagates itself over the whole system. The heat of the surface is augmented, and the increased temperature is experienced particularly about the forehead and eyebrows, and the skin is bedewed with a breathing perspiration. At the same time an increased strength and frequency of pulse is felt. The whole muscular system acquires energy and elasticity; the involuntary muscles especially become more powerful and vigorous in their action; the respiration is gently accelerated. The nervous system partakes of the impulse communicated to the frame, and the spirits as well as the courage of the individual rise, liveliness and regularity characterising the whole functions of the system.

That the white oxide of arsenic is a tonic, therefore, is sufficiently clear; and that its employment in such doses as we have stated is not only safe but beneficial, may be satisfactorily proved. Not only are old worn-out horses endowed with new vigour, improved appetite, &c., by its use, but pigeons to which this article is given show greater appetite and liveliness than others without it; and in Upper Styria the peasantry use it as a seasoning with many articles of food, such as cheese.

It will not, we trust, be supposed that by bringing forward these facts and statements, we desire to lead any one to make a hasty or inconsiderate use of this very powerful agent. We only wish to show that much prejudice exists against it, in order that when circumstances seem to require its use, medical men may not be deterred from employing it from ignorance of its qualities, nor have to encounter unnecessary difficulties from the objections of others. That oxide of arsenic may accumulate in the system, or may give rise to slow poisoning, cannot be questioned; but if exhibited in appropriate cases, the morbid state of the system seems to act as an antidote to it, just as it acts as an antidote to the disease, health being the result of their neutralising power. Every medical practitioner knows what large doses of opium may be given with safety and benefit in tetanus, and some other diseases. It has been stated under ANTIMONY, that very large doses of tartrite of antimony can be borne in certain states of the system; and in the West Indies, during the state of insensibility following the bite of a snake called the *coluber carinatus*, eight grains of the white oxide of arsenic, and eighty drops of the tincture of opium have been given in the course of four hours, that is, one grain every half-hour, with the best effect. (See Paper by Mr. Ireland in 'Medico Chir. Transactions,' vol. ii. p. 393.)

White oxide of arsenic is not often given in the solid form, nor, owing to its variable solubility, is the solution frequently employed; the form most generally chosen is that of its combination with potass, or arsenite of potass: which is the basis of the *liquor Potassæ arsenitis* of the London Pharmacopœia, in the preparation of which the quantity of potass is scarcely sufficient to saturate the whole of the acid, some of which must consequently remain free in solution or be deposited. Before the regular introduction of this into medical practice, it had long been employed in Lincolnshire for the cure of intermittents, under the name of the *Tasteless Ague Drops;* and, from having been introduced into practice by Dr. Fowler, it is frequently called *Fowler's Solution.* It is never given in larger quantity than three or five drops, and should always be taken about half-an-hour after a meal, to prevent it coming into direct or immediate contact with the inner coat of the stomach.

Being considered eminently an anti-periodic [AGUE], it has been used in most diseases which partake of a periodic character; the chief of these we shall here notice, along with two or three others not possessed of a periodic character. It is most frequently employed in intermittent fevers; the greatest advantage is derived from it in the tertian and quartan forms, the quotidian often resisting this and all other remedies. Its beneficial effects may be increased by giving calomel first; cinchona bark may be given also during the employment of arsenical medicines, but it should rather be alternated with them than given at the same time; certainly they should not be given in the same formula or prescription, though, if the patient be very weak, other tonics may be given along with them. Opium is sometimes advantageously given along with them, but it should be employed in very small quantity.

It has sometimes been given in remittents, which approached nearly to the character of intermittents.

In rheumatic cases it has been used, and is most successful when the pains are markedly periodic, or true to a particular hour in their return. It is equally applicable whether these be general or local, as in some rheumatic affections of the eye. (See Travers 'On Diseases of the Eye.') In nodosities of the bones from rheumatism it is also very valuable.

In some affections, more especially of the nervous system, such as *tic doloureux*, and other neuralgic pains, it is useful. In *cardialgia*, or heartburn, when chronic, if combined with belladonna, it often affords speedy and lasting relief. It has sometimes been advantageously employed in hooping-cough, angina pectoris, epilepsy, and chorea, when tonics were required. In some chronic nervous affections of the mental faculties it has been found useful, such as melancholia and hypochondriasis; and in hydrophobia, tetanus, and the bites of serpents, it is certainly more valuable than any other means we are acquainted with. Mr. Brodhurst has proposed its employment during the period of *incubation*, before the formidable symptoms manifest themselves; this is a wise and sensible proposition.

In cancer it has been employed both internally and externally; the form generally used in the latter way is *pâte arsenicale*, but it is not free from danger, and requires great caution. Its internal employment has been mostly in cases where it depends upon constitutional rather than local causes; but if hectic fever be present, it will do more harm than good. It seems to be of more service in cancer of the lip and face, than in affections of the glands, as the mammæ or testicles. In cutaneous diseases, such as lepra or elephantiasis, it is often serviceable, and its beneficial action may be increased by giving *liquor potassæ* along with it.

We hold that the previous failure of other and more common remedies is a sufficient justification of the employment, with due caution, of arsenic in any of these diseases.

In case of an overdose, or of intentional poisoning by arsenic, it is proper that we should indicate an antidote, and point out the mode of treating such a casualty: both these are difficult. First, then, in the case of a substance so sparingly soluble, we cannot see how the stomach-pump is likely to be of service; more especially as the white oxide either adheres firmly to the inner coat of the stomach, or gets imbedded in its substance. A more rational plan is to give a large quantity of lime-water, cold, as the arsenite of lime is almost insoluble, and nearly inert. After that, an emetic of sulphate of zinc (ʒ i. in a pint of distilled water); then copious draughts of oil (castor oil if possible), or milk. After which the case must be treated on general principles. [ANTIDOTES; POISONS.]

The *Liquor Arsenici Chloridi* of the London Pharmacopœia is thought to be more serviceable in cutaneous diseases than the other preparations. Arsenite of soda has some advantages. (See Lloyd Bullock in 'Journal of Pharmaceutical Society,' vol. x. p. 359.)

Arsenic has been detected by Ménard in the mineral waters of Mont-dore, Ste. Nectano, and other springs, in which it exists in combination with various bases, especially soda. These springs are celebrated for their curative effects in cutaneous diseases. The efforts of the legislature to restrain the illegal employment of arsenic are praiseworthy, but can scarcely reach the multiform employments of it which are injurious to health. The paper-hangings of our rooms, the candles we burn, the toys and sweetmeats our children handle and devour, are too often coloured with arsenic.

In cases of poisoning, antidotes are needful; but no very efficacious one can be recommended. Hydrated sesquioxide of iron is useful in large doses, but is seldom at hand; hydrated magnesia, in large doses, is useful, and more generally procurable.

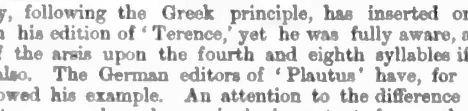
ARSIS (ἄρσις, elevation) is a technical term in ancient music and ancient metrics. In the latter it denotes that elevation of the voice which we now call metrical accentuation; but whether it consists in a higher musical note, a greater volume, or greater duration of sound, or rather, perhaps, in all the three combined, is matter of dispute. The musician is said to have struck the ground with his foot to mark the arsis, and hence the Latin term *ictus* (stroke) has been used in the same sense. The arsis is opposed to the *thesis* (θέσις) or depression of the voice, the precise meaning of which is of course subject to the same ambiguity. The order in which the arsis and thesis recur, constitutes the law of any verse or metre. It must be recollected, however, that although only two terms are used, yet one arsis may be more energetic than another, one thesis weaker than another. Thus in the ordinary iambic measure of six feet, there are six places marked by the arsis, namely, every even syllable, the second, fourth, &c.; but the stronger arsis attaches itself to the second, sixth, and tenth. The Latin writers on metrics accordingly called the verse we are speaking of sixfold (senarius), while the Greeks applied it to the name of a triple metre (trimeter), the former including every arsis, the latter only those which are more marked.

Bentley, following the Greek principle, has inserted only three accents in his edition of 'Terence,' yet he was fully aware, and often speaks of the arsis upon the fourth and eighth syllables if not the twelfth also. The German editors of 'Plautus' have, for the most part, followed his example. An attention to the difference of power in the stronger and weaker arsis is important for another reason. After the stronger arsis, the thesis must be very weak to mark the contrast, while after the other there may be admitted even a long syllable, provided it has not also the accent. The laws of the iambic, trochaic, Sapphic metres, &c., will afford examples. In many metres, certain variations in the place of the arsis are not merely permitted, but even desirable, at least in poems of any length. In our own iambic metre of five feet, commonly called the heroic verse, the arsis is often found upon the first instead of the second syllable. Again, in the hexameter of Homer, the dactylic arsis, or the arsis followed by two depressions, is the prevailing law; whereas in the Latin hexameter, in addition to the pure dactylic rhythm, we find a large proportion of lines in which there is an approach to an iambic rhythm at the beginning of a line, as in the second verse of the 'Æneid':

"Itáliam fáto prófugus | Lavínaque vénit.

Perhaps this variety may have been more pleasing to the Roman ear, as it is certainly more common in Latin hexameters, from an old attachment to the Saturnian verse, in which the iambic cadence commences, and the trochaic terminates the line; or, in other words, perhaps the Latin hexameter may be a compromise between the Greek hexameter and the Latin Saturnian. A metre in which the arsis is very commonly misplaced by the English reader is the Sapphic, the true melody of which runs thus:—



where and mark respectively the stronger and weaker arsis; the thesis; whereas the ordinary English intonation is

&c.; and thus a melody, which by Horace was selected as peculiarly adapted to the solemnity of the religious hymn, has been degraded by the English into the fit vehicle of burlesque and ridicule. An example may be seen in the pseudo-Sapphic ode on a Knife-grinder in the 'Antijacobin.' [Prosody; Accent.]

ARSIS and THESIS, in music, the rising and falling of the hand in beating time, from ἄρσις, "raising," and θέσις, "depressing." These terms were also used by the early composers to express the inversion of a subject. *Per arsin* is, when the air, or counterpoint, descends from acute to grave: *per thesin* is, when it ascends from grave to acute.

ARSON (from *ardeo*, to burn), in the technical meaning of the term, at common law, signified the offence of voluntarily and maliciously burning the house of another. This offence always amounted to felony by the law of England, and was punishable with death. But in order to constitute burning a felony at common law, it was necessary that the building destroyed should be a dwelling-house, or a part of it, or at least some of the buildings attached to it. The property destroyed must also have been in the possession (*suo jure*) of some other person than the supposed offender at the time of the fact committed. On these grounds, and on account of the obscure phraseology of several statutes, nice and doubtful questions constantly arose upon the trial of persons charged with arson, both with respect to the nature of the buildings destroyed, and the character of the possession of the proprietor. These ambiguities were removed by the statute 7 & 8 Geo. IV. c. 30, sec. 2, afterwards repealed by the 7 Will. IV. and 1 Vict. c. 89, by which (as extended and amended by subsequent acts) unlawfully and maliciously to set fire to any dwelling-house, any person being therein, is a capital felony; and unlawfully and maliciously to set fire to any church or chapel, or to any house, stable, coach-house, out-house, warehouse, office, shop, mill, malt-house, hop-oast, barn, or granary; or to any building or erection used in carrying on any trade or manufacture; or to any hovel, shed, or fold, or to any farm building, or any building or erection used in farming land, whether the same or any of them respectively be in the possession of the offender or of any other person, with intent thereby to injure or defraud any person is a felony punishable by penal servitude for life, or for a less period, or by imprisonment not exceeding three years. Setting fire to any hay, straw, wood, or other vegetable produce being in any farm-house or farm-building, or to any implement of husbandry therein, with intent thereby to set fire to such house or building, and to injure or defraud any person, involves (by the 7 & 8 Vict. c. 62) the same penalties as setting fire to the house or building with the like intent.

The before-mentioned statute 7 Will. IV. and 1 Vict. c. 89, also provides for the offence of setting fire to vessels, coal mines, and also to stacks of grain and vegetable produce, peat, coals, charcoal, or wood. By the 9 & 10 Vict. c. 25, s. 7, attempting to commit any of the above offences is made a felony which is now punishable by penal servitude not exceeding fifteen years, or imprisonment not exceeding two years.

The burning of a man's own house, if it be situate in a town, or so near to other houses as to endanger them, is a misdemeanour at common law, punishable with fine and imprisonment.

ART AND PART is a term used in Scotch law to denote the charge of contriving a criminal design, as well as that of participating in the actual perpetration of the criminal fact. The derivation of the phrase is uncertain. Sir George Mackenzie, in his 'Discourse upon the Laws and Customs of Scotland in matters Criminal,' says, that "by *art* is meant that the crime was contrived by the art or skill of the accused (*eorum arte*); and that by *part* is meant, that they were sharers in the crime committed, et quorum *pars* magna fui." By other writers it has been considered as an abbreviation of the Latin phrase of *artifex et particeps.* It is a charge of very extensive meaning, comprehending not only the offence of accessories before and after the fact according to the English law, and the *ope et consilio* of the Roman law, but also all interference and assistance at the time of the commission of the criminal act. By an ancient Scotch statute, passed in 1592, it is required that in all criminal libels or indictments, the offenders shall be charged as having committed the imputed offence 'art and part.' This enactment was occasioned, as its preamble intimates, by the frequent instances of failure of justice in criminal trials, in consequence of a variance between the evidence and the particulars detailed in the libel or indictment. Thus, previously to the statute, if A and B were charged with murder, and the indictment stated that A held the deceased while B stabbed him, and it appeared in evidence that the facts were reversed, and that B held him while A stabbed him, neither of the accused persons could be convicted. But by the insertion of the charge of 'art and part,' such a failure of justice could not occur; for in fact, both the panels, or prisoners, are substantially guilty 'art and part,' and are therefore comprehended in the general charge of the indictment. This subject is very copiously discussed in Hume's 'Commentaries on the Law of Scotland respecting the Description and Punishment of Crimes.'

ART-UNIONS. In the 'Report' issued in 1836 by a Select Committee of the House of Commons, which had been appointed in the preceding year "to inquire into the best means of extending a knowledge of the arts, and of the principles of design, among the people (especially the manufacturing population) of the country," and "to inquire into the constitution, management, and effects of institutions connected with the arts," it is observed that among exhibitions connected with the encouragement of art, the attention of the committee had been called to the institutions established in Germany under the name of 'Kunst-Vereine,' and which were even then being introduced into this country. "These associations, for the purchase of pictures to be distributed by lot," observe the committee, "form one of the many instances in the present age of the advantages of combination. The smallness of the contribution required brings together a large mass of subscribers, many of whom without such a system of association would never have been patrons of the arts." The committee further remark that Waagen and Von Klenze, two of the witnesses examined by them, highly estimated the advantages conferred on the arts by such associations, which, according to Waagen, were introduced into Prussia about the year 1825, under the patronage of the king and his minister Von Humboldt.

Down to the time at which this 'Report' was published, such associations had made comparatively little progress in this country; but shortly after its appearance a society was established under the name of 'The Art-Union of London,' which immediately obtained considerable support, and which soon became an important institution. The professed objects of this institution are "to aid in extending the love of the Arts of Design within the United Kingdom, and to give encouragement to artists beyond that afforded by the patronage of individuals;" and the mode in which these objects are attained is briefly as follows: —Every member of the association subscribes annually the sum of 21*s.* or upwards, those who choose to subscribe two, three, four, five or more times that amount being considered to hold a proportionate number of shares in the prospective benefits; and, on the closing of the annual subscription-list, which takes place early in the spring, the committee of management set apart a portion of the aggregate sum for the purpose of engraving and printing some work of art, a copy of which is given to every subscriber for each guinea subscribed. By the combination of a very great number of persons to subscribe for this one work of art, and the avoidance of risk, incidental expenses, and publisher's profits, this print, though superior to what would be charged a guinea in the ordinary course of trade, is supplied to the subscribers at so small a cost as to leave the greater part of the sum subscribed, as a fund applicable to the purchase of pictures, sculpture, and other works of art. This sum is divided by the committee into several portions, or prizes, ranging at the present time (1859) from 10*l.* to 200*l.*, and on the day appointed for the annual meeting of the society, these prizes are distributed among the subscribers by a process resembling the drawing of a lottery, which gives an equal chance for every guinea subscribed. The prizeholders are then allowed to select a painting or piece of sculpture to the value of their respective prizes from any of the annual exhibitions of works of art in the metropolis, for the current year, which works, when selected by the prizeholders, are purchased and paid for by the committee, who, at the close of the exhibitions, collect the pictures and sculptures together, and exhibit them gratuitously for some weeks, first to the subscribers and their friends, and afterwards to the public. When the selected works fall short of the amount of the prize, the difference is carried by the committee to the Reserved Fund of the association, and when they exceed it, the difference is paid by the prizeholder. A portion of the funds is also applied to the production of bronzes and medals, porcelain groups and statuettes, etchings, photographs, &c., which are distributed as prizes at the annual meeting. The amount of subscriptions in the first year, which closed in 1837, was 489*l.* 6*s.*, but it increased so rapidly that in 1844, it had reached 14,848*l.* It has since fluctuated considerably, but the last report showed that the subscription for 1858 was 11,658*l.*, of which 3,060*l.* was set apart for the purchase of works to be selected by the subscribers; 2,249*l.* for statuettes, bronzes, &c.; and 2,998*l.* for the engraving.

The popularity of the Art-Unions, properly so called, brought into operation several lotteries for the disposal of works of art, in which, notwithstanding the adoption of a similar course of proceeding, the principle was so essentially different, as to render them in fact mere revivals of a species of gambling speculation which has long been illegal in this country; and the difficulty of dissociating Art-Unions from lotteries unquestionably illegal, led government to issue a notice in April, 1844, which had the effect of suspending their operations for some months. A parliamentary committee was subsequently appointed to inquire into the subject, with a view to placing them on a safe and permanent basis, and so rendering them as subservient as possible "to the improvement and diffusion of art through the different classes of the community;" the result of which was the passing in the session of 1844, of a short Act to indemnify the managers against such penalties as they might be considered subject to; and eventually an Act was passed (9 & 10 Vic. c. 48), to legalise Art-Unions under the condition, that a royal charter shall have been obtained, or that the deed of partnership or other instrument constituting the association, with the rules and regulations, shall have been submitted to and approved by a Committee of the Privy Council.

Having described the principles and mode of procedure of the Art-Union of London, it may be proper to notice some other Art-Unions which have been since established, and which have adopted a different mode of distributing the selected works of art among their prizeholders. Of these, the oldest and most important is the Art-Union of Glasgow, established in 1841, and of which the annual subscriptions for the year 1855 amounted to 20,336*l.* As in the Art-Union of London, a copy of an engraving is given to each subscriber; but the pictures which are allotted as prizes are selected by the committee, the prizeholders having no choice, but each receiving the picture which falls to his lot at the annual meeting. The prizes for 1858 vary in nominal value from 3*l.* 3*s.* to 350*l.*

The Art-Union of Ireland, established in 1858, proposes to get rid of the great outlay rendered necessary by presenting each subscriber with an engraving; and instead, to increase the proportion of prizes, so that while in the older Art-Unions the prizes are in the proportion of one to every twelve or fifteen subscribers, in this, the prizes, "making large provision for those of the higher class, may be estimated at about one in every six" ('Address' of Committee). Further, every prize is to be selected by the prizeholders; and while "all above 5*l.* must be selected from paintings or sculpture exhibited in Ireland," prizes below that sum (of which there are to be a considerable number), may be selected from *any* work of art "anywhere on sale in Ireland, of a class approved by the committee."

The Crystal Palace Art-Union, established in 1858, chiefly aims at the production and distribution of works of ornamental art of a high order of artistic merit. Each subscriber of a guinea has the right of selecting one of the objects of ornamental art (including bronze and parian statuettes, articles of ceramic ware, photographs, &c.), "executed under the supervision of the council, the copyright of which, as far as possible, will be vested in the society," and of which the ordinary trade price would be not less than the amount of the subscription. Besides which, every subscriber is to have a chance of obtaining a prize from among works of fine or ornamental art, "of the highest class," which are to be selected by the council and exhibited at the Crystal Palace previous to the annual drawing.

ARTANTHE ELONGATA, the plant which yields the medicina agent known by the name of Matico. This plant belongs to the natural order *Piperaceæ*, and is the *Piper angustifolium* of Ruiz and Pavon, the *Piper elongatum* of Vahl, and the *Stephensia elongata* of Kunth. Although this plant has long been used by the natives of Peru as a remedy in various diseases, it was not known till recently that it produced the substance known as matico. The term matico is, however, applied in Peru to other substances, and Dr. Lindley states that the leaves of *Eupatorium glutinosum* were sent to him under that name.

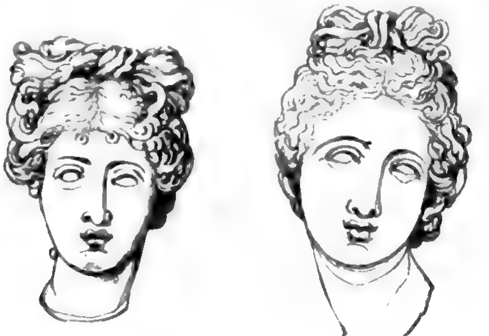
Artanthe elongata, the true matico plant, is a shrub about 12 feet high, with jointed stem and branches. Its leaves are harsh, short-stalked, lanceolate, acuminate, pubescent beneath, tessellated or rough on the upper side on account of the sunken veins. The spikes are solitary, cylindrical, and opposite the leaves; the bracts lanceolate and the flowers hermaphrodite.

It is a native of Peru, and is found at Huanuco, Cucheco, Panao, Chaclea, and Muna. It flowers from July to September. An infusion made with cold water is the best form of administration.

A'RTEMIS, one of the ancient Greek divinities, known to the Romans as Diana, whose attributes were so numerous and of such opposite kinds, that it would be difficult to imagine how they should have been assembled in the same deity, if we did not know that the imaginative spirit of the Greeks loved to invest their gods with the most opposite characters. In the poetry of Homer and Hesiod she appears as the daughter of Zeus and Leto (Latona), sister of Apollo, and the goddess who presides over hunting. She traverses the woods, armed with the bow and arrow, and attended by numerous nymphs. Her bow is employed, not only against the beasts of the forests, but also against man; and in those early poems she is represented as never yielding to the allurements of love. She is a chaste and pure virgin. In the 'Orphic Hymns' (35, 36), we find her invested with other attributes. There she assists at childbirth, is the assuager of pain, looks with benignant eye on the labours of man, and is the author to him of abundant harvests, of peace, and of health. In this she seems to have appropriated to herself part of the duties of Ceres, and indeed, according to Æschylus, she was daughter of that goddess. In a temple at Megalopolis in Arcadia her statue stood by the side of that of Ceres, and she was clothed with the skin of a hind; a quiver hung from her shoulder; she had a lamp in one hand, and two serpents in the other. (Pausan. viii. 37.) In the Greek tragic poets she appears under another character, according to which the favour of the goddess must be obtained by the sacrifice of human victims. Iphigenia, daughter of Agamemnon, on her return from the Tauri, introduced this barbarous feature in the worship of Artemis. At Sparta there was a temple of Artemis Orthia, where they exhibited an old wooden statue, said to be that brought by Iphigenia from the Tauri; and though in later times human victims were not offered, the thirst for blood, which the goddess was supposed to feel, was satisfied by the severe scourging of the Spartan youths before her statue. (Pausan. iii. 16.) All these various fables were collected by the Alexandrine poets of later times, and fitted to one another so as to form a whole.

The worship of Artemis was very general throughout Greece and the colonies; but she was more particularly the goddess of the Arcadians, if we may judge from the numerous temples found in that district. There almost every height, fountain, and river supplied her with a distinctive epithet, so the poet Alcman (who flourished probably B.C. 672) says, that she derives names from ten thousand mountains, cities, and rivers. She is Lycoatis on Mount Mænalus (Paus. viii. 36), Cnakeatis at Tegea (viii. 53), Stymphalia on Stymphalus (22), Cnacalesia and Condyleatis at Caphyæ (23): and it is curious to observe that this old Peloponnesian divinity is frequently found in connection with streams and rivers. She is *amnium domina*, 'mistress of rivers,' in Catullus (34, 12); λιμένεσσιν ἐπίσκοπος, *inspectress* or *superintendent of ports*, in Callimachus (iii. 40). Again, as Apollo was identified, by the later Greek writers, with the sun (Helios), so was Diana with the moon (Silene). [APOLLO.]

Artemis was a favourite subject with the artists of Greece, and they have generally represented her as a huntress. They endeavoured to invest her with all the freshness and vigour of youth: in the old style, where she is generally clad in the stola, the artist still contrived to indicate her full and well-formed figure. In the works of Scopas, Praxiteles, and Timotheus, Artemis was, like Apollo, represented of a slender form; her hips and breasts without the fullness of womanhood. The countenance is that of Apollo, only with a softer expression and more full; the hair is sometimes bound over the forehead, but more frequently in a bunch behind or on the top of the head in the



(Heads of Artemis in the British Museum.—First Græco-Roman Saloon.)

manner peculiar to the Dorians. The dress is a Doric vest (χιτὼν), either tucked up high, or reaching to the feet; and the shoes are Cretan. Sometimes a dead or dying stag lies at her feet. As a huntress she is represented in rapid motion. In temples she bears a torch as well as a bow. (See Filhol, 'Galérie Napoléon,' v. 366; Visconti, 'Iconographie,' xlii. 1; 'Diana Lochæa' in Millin, 'Monuments inédits,' ii. 34. (This subject is treated fully in Müller, 'Archäologie der Kunst,' §§ 363—365.) There are several representations of Artemis in the British Museum, besides the heads given above. One, a statue clothed in a long vestment, is a very fine figure, but has been incorrectly restored. In one of the slabs of the Phigalean frieze she is figured with Apollo in a car drawn by stags. We have not entered into the question whether there were several goddesses of this name, distinct from each other in their character and attributes; but we think that this opinion is by no means improbable. She is considered the same as the Bubastis (Pasht) (Herod. ii. 59) of the Egyptians, and is represented as a female with a lion's head. (Seyffarth, 'Geschichte des alten Ægypten,' Leipzig, 1833; Müller, 'Die Dorier' (translation) vol. i.; Voss, 'Mythol.' Br. iii. 1.

In the Roman mythology, the goddess *Diana* was considered as corresponding with the Artemis of the Greeks. But much confusion has arisen in the study of ancient mythology from the habit of looking upon the names of the Greek and Roman deities as convertible with one another. Where there are some points of resemblance, there are often still more of dissimilarity, especially as regards those deities which were the objects of religious honour among the Romans before the introduction of Greek and Asiatic forms of worship. The Saturn of the Romans, for example, is far from identical with the Kronos of the Greeks; Minerva, again, differs much from Pallas, and Diana from Artemis. The greater part of the deities strictly belonging to the Romans have names which have grown out of the language itself. This cannot be said of the Greek deities. Thus Dianus and Diana are properly two adjectives, derived from *dies*, 'day,' or, perhaps, originally 'light,' precisely as *quotidianus* from *quotidie*, and in this way they were the appropriate names of the god and goddess of light, the former representing the sun or greater light, the latter the moon. Dianus, by an easy change, would become Janus, as Diana, we know, was corrupted by the rustic population into Jana in their hymns to the new moon, beginning *Jana novella*. Thus again, *Bellona* is properly a feminine adjective, which with the noun *dea* signifies the goddess of war (from *bello*, war); so Pomona, the goddess of fruit (*pomo*); Portunus, or Portumnus, the god of harbours (*portu*); Vertumnus, of change (*versu*, anciently *vertu*); Silvanus, of woods (*silva*); Luna, or Lucina, the goddess of light (*luc*, and perhaps *luci*): Fortuna, the goddess of chance (*fort*, or more probably from an obsolete noun *fortu*). On the same principle, no doubt, are formed the names of Vulcanus (compare *fulgeo*, φλέγω, shine, blaze), Neptunus (compare νίπτω, wash, and *nympha*, a goddess of water), Saturnus (compare *satur*, full), Picumnus, Pilumnus, Faunus; and we might perhaps look upon Auctumnus (from *auctu*, increase) as a deity.

Another principle which pervades the Roman mythology is the division of each object of fear or desire between deities of either sex. (Niebuhr, 'Roman Hist.') We have already seen Dianus and Diana. Besides these, there occur Saturnus, the god of plenty; Ops, the goddess of plenty; Vulcanus and Vesta, the god and goddess of fire; Tellumo and Tellus, of earth; Neptunus and Nympha (Nimfa would be a more correct Latin form), of water; Jupiter or rather Jove, and Juno, of air. In the same way they had Mavors (or Gradivus), together with Bellona, to preside over war.

To return; as the huntsman of Italy preferred the night for his sport—

> Manet sub jove frigido
> Venator, teneræ conjugis immemor—

Diana, or the moon, naturally became the patroness of the chase, and so of the wood. Again, in her character as goddess of light, her aid was invoked in parturition. In this latter office she was also called Lucina, a term of precisely the same import from *luc*, 'light;' and the identity of the two goddesses is established by the contracted form Luna, which, like Diana, is the name of the moon.

Diana had a temple on Mount Aventine, and another near Aricia. Indeed her worship belonged strictly to Latium and the plebeians of Rome.

ARTEMI'SIA ABSINTHIUM (WORMWOOD)—*Medical Properties of.* This indigenous perennial plant is met with on waste places, but what is required for medical use is mostly cultivated. The upper part of the stem, with the leaves and unexpanded flowers, should be collected, for these parts possess the peculiar aroma, with a strong bitter taste; while the lower part of the stem is merely aromatic, and devoid of bitterness. (Geiger.) It imparts its properties to water, to alcohol, and to fermented liquids. The medicinal forms of it are—the watery infusion (best made with cold water) and the extract: but the domestic preparations are numerous; these are made either by digesting it with alcohol, to form a tincture, or by distilling it with spirits; that obtained in this last way from Switzerland is termed 'Eau d'absinthe,' and is a favourite liqueur, which becomes milky on the addition of water. It is also steeped in wines (Wermuth), or even rendered a constituent of the wine at the time of fermenting it [WINES], or drunk in small quantity while using any of the sweet wines, such as Tokay. This practice may have been derived from the ancients, most of whose wines were very rich and luscious, and who used wormwood, both before and after taking wine, to counteract the effects. (Paulus Aegineta.) In the west of England it is frequently steeped in cider, to be drunk by persons disposed to calculous complaints: a most judicious proceeding. Elsewhere it is steeped in ale. In the north of Europe it is used as a substitute for hops in the preparation of beer, and is nearly as good, as a little of it will preserve either beer or weak wines when ready to turn. The analysis by Heyne of 100 parts of the dried plant gave as its composition—volatile oil ?; bitter extractive, 4·0; gummy mucilage, 15·1; resin, soluble in ether, 8·6; resin, insoluble in ether, 3·4. The rest consists of woody fibre, water, and loss. Braconnot analysed the watery extract, and found—volatile oil, 0·15; green resin, 0·50; bitter resin, 0·233; albumen, 1·250; starch, 0·133; azotised matter, 1·333; bitter azotised matter, 3·0; woody fibre, 10·833; absinthate of potash, 0·333; sulphate of potash and chloride of potassium, traces; water, 61·2. Recently, a peculiar principle termed *Santonine*, crystallisable, colourless, and almost tasteless, and stated to possess very valuable anthelmintic properties, has been obtained from several species of artemisia, particularly Art. Contra. ('The Chemist,' vol. v., pp. 36, 91.) The term *Absinthine* is applied to the peculiar or bitter principle of Artemisia absinthium. The so-called salt of wormwood is merely the impure carbonate of potash, obtained from the incineration of this plant, which is very rich in alkaline salt.

Wormwood possesses the properties common to aromatic bitters, but it seems to possess also some peculiar ones rendering it worthy of more attention than it receives—neglect of indigenous remedies being prevalent in all ages. The bitter principle is readily absorbed, so that the flesh of animals fed upon it becomes manifestly bitter. Some have alleged that a narcotic power exists in it, and that the milk of cows, or of nurses, to whom wormwood is given, is noxious to infants. This is not clearly proved, nor is it certain that ale in which wormwood has been steeped (purl) is more heady than other ale. Absinthium greatly increases the appetite, and promotes digestion, particularly in torpid systems and debilitated constitutions. Those who, by excess, have impaired their stomachs, have recourse to wormwood to renovate their powers. Hence the demand among gourmands for the spirituous preparations, such as the crême d'absinthe. Where there is much gastric irritation or vascular excitement this is most improper. An infusion (made with cold water) may be given to consumptive patients, if no inflammatory state of stomach exists, with very great advantage, especially if aromatic sulphuric acid be added.

ARTERIES, DISEASES OF. Besides aneurism, the arteries are subject to other diseases. [ANEURISM.] The arterial tissues are liable to inflammation, which may be acute or chronic.

Acute Arteritis is either limited to a particular spot, or it spreads along the course of the artery. When limited, this disease arises from external injury, and is a common result of wounds and ligatures. In the milder forms, this inflammation is attended with the exudation of a plastic matter, which fills up the artery and leads to its obliteration, a result which is sought for in the application of a ligature to arteries. The inflammation may, however, proceed to suppuration and ulceration, when the coats of the artery are opened, and hæmorrhage is the result. In every instance of ligature such a result is carefully to be avoided. A still more intense form of inflammation may occur, and the result will be the death of the part and gangrene—a result which sometimes follows wounds involving the destruction of the arterial tissue. It may also come on from a ligature being applied too tightly.

In the treatment of such cases the ordinary remedies for inflammation should be applied. Cooling applications should be made to the part, and rest and an antiphlogistic regimen enjoined.

The spreading form of arteritis occurs in middle age, in persons of broken constitution. It is seldom confined to one vessel, but affects the arteries of a whole limb. The tracks of the inflamed arteries are painful to the touch, there is slight induration of the affected arteries, the pulse is feeble, and has a peculiar thrilling stroke. The surrounding textures are not often involved in the disease. The pulse in the affected arteries is feeble, has a thrilling stroke, and gradually diminishes till it finally ceases. The tissues surrounding the arteries are seldom affected with the inflammation, and the skin is not altered, except that it is pale.

The effects on the arterial coats are the production of turgescence, and a loss of the smoothness of the internal coat. There is a tendency of the blood to coagulate and become adherent in the inflamed vessel, and ultimately the canal becomes blocked up. In proportion as these changes are extensive, will be the general local mischief. The temperature and sensation of the part are diminished, and gangrene, unless the disease is arrested, sets in.

The treatment consists in the employment of antiphlogistic measures. Leeches may be applied to the part, and calomel and opium given internally. The employment of stimulants, both internally and externally, should be avoided.

Chronic Arteritis is of more frequent occurrence than acute, and is a state of the artery in which abnormal deposits are formed in the coats of the artery, and which frequently lead to the more serious derangements of the arteries. This disease is not to be detected by any symptoms during life, but is recognised after death by its effects on the arteries. The artery may be affected in spots, or throughout its whole extent. The internal coat of the artery is enlarged, and is less smooth and serous on its surface. Between the internal and middle coat there is a deposit of a soft, cheesy-looking, granular matter, either in points or patches. This deposit is usually called *atheromatous.* Under the microscope it is found to consist of fatty granules and molecules, which are frequently associated with crystals of cholesterine. The middle coat of the artery is frequently altered in its character, presenting a thin yellow opaque appearance. From this cause the elasticity of the artery is much impaired, its cohesion is diminished, it easily stretches, and is apt to tear. It is in this condition that dilatation of the artery, or true aneurism, takes place. It may also become the seat of ulceration, or it may tear at once, thus leading directly or indirectly to dangerous hæmorrhages. Although these changes are supposed to take place as the result of inflammation, there is no reason to believe that they may not go on quietly without inflammation. It is not improbable that the changes which thus go on in the artery are identical with those which produce fatty degeneration in the other tissues of the body. When this change takes place in the small arteries of the brain, it not unfrequently leads to an attack of apoplexy, from the rupture of the vessel and the effusion of blood upon the brain.

Calcareous deposits between the inner and middle coats of the artery may take place in the same way as the fatty deposits. In this manner the artery becomes ossified. In this case the arteries become hard and non-elastic, the internal coat is dry and shrivelled in appearance, and atheromatous deposits are found mingled with the calcareous.

The treatment of these forms of arterial disease, where they are suspected to exist, should consist in removing all causes that can contribute to hasten the changing condition of the arteries, and to prevent that action which may facilitate the enlargement, or endanger the bursting of the arteries.

Vascular or Erectile Tumour. This is a form of disease of the arterial tissue, sometimes called *Aneurism by Anastomosis.* There are three varieties: 1. The capillaries of the integument may become dilated so as to produce a discoloured elevation of the skin, more or less depressed. These tumours bleed copiously on the slightest abrasion, or from ulceration. It is commonly called *Nævus.* 2. The veins and arteries may be enlarged in the sub-cutaneous areolar tissue, producing a dark livid tumour of the skin. Copious hæmorrhage occurs from any rupture of the skin, but this may be generally arrested by pressure. Such tumours may occur under the mucous membrane, and are exemplified in those forms of hæmorrhoids which are situated partly within and partly without the verge of the anus. 3. The true erectile tumour, which is composed of dilated blood-vessels, which are closely crowded together, and open into each other at many points. "These openings may be of secondary formation; the result of close apposition in the dilated vessels. Or more probably they are primary; the structure consisting of a network of dilated capillaries; the openings of communication being the ordinary and original inosculations, and what were intervascular spaces being now condensed into mere fibrous bands. The whole constitutes a vascular network of great capacity and activity of circulation, supplied, for reception of the returned blood, with large and tortuous veins, whose lining membrane is plainly continuous with that of the abnormal vascular cells. Also in the neighbourhood are to be found the feeding arteries; originally, perhaps, twigs, now enlarged to trunks pulsating strongly, and obviously carrying on a plentiful and active supply." (Miller, 'Practice of Surgery.') Such is the nature of those tumours which partake of the character of true erectile tissue. Like this tissue also, these tumours become enlarged and diminished in size, according to the sluggishness or activity of the blood circulating through them. They are compressible, elastic, and of a reddish hue. They are usually subcutaneous, but they are also submucous. The most common situations are beneath the integuments of the face, head, neck, back, and buttocks. The tumour pulsates synchronously with the heart, and may be considerably diminished in size by pressure, but resumes its usual condition when the pressure is withdrawn. On auscultation, a beat is heard, dull and rough, sometimes accompanied by a vibratory thrill.

Ulceration is likely to occur in these tumours, and lead either to great hæmorrhage or their cure.

Erectile tumour may be treated in three different ways:—

1. The tumour may be removed. This is always better done by the ligature than by the knife.

2. The tumour may be starved by diminishing the arterial supply. This is done, as in cases of true aneurism, by the application of a ligature to the artery or arteries which supply the tumour with blood.

3. The structure of the tumour may be changed. This may be effected in various ways, as by pressure, the introduction of a needle, the application of caustic potash, nitric acid, or other agent. A hot needle may be run through, or a wire connected with the poles of a galvanic battery may be passed through the tumour. All these plans have been found to succeed with small erectile tumours.

Varix of the Arteries.—A tortuous and dilated condition of the arteries frequently comes on in the smaller arteries, and produces painful tumour. It may be removed in the same manner as varicose veins.

ARTERIOTOMY is the term applied to the opening of an artery for the purpose of drawing blood, as phlebotomy is applied to the same operation in a vein. When it is thought desirable to take blood in large quantity and with much rapidity, it is better taken from an artery than from a vein. This operation, however, is more difficult to perform, and may be attended with ulterior consequences. Hence phlebotomy or venæsection is always preferred, except under urgent circumstances, as the means of drawing blood from the system. When arteriotomy is performed for the sake of blood-letting, one of the superficial anterior branches of the temporal artery is generally selected. In this position the wound is easily healed afterwards by pressure. The accidental wounding of an artery, as is sometimes the case in bleeding from the veins at the bend of the arm, may lead to false aneurism and the necessity of placing a ligature round the wounded artery. Sometimes false aneurism follows arteriotomy in the temporal artery, and in this case it becomes necessary to ligature the arteries on each side of the wound. Sometimes on removing the compress after arteriotomy, an ulcer is found to be formed. If the ulceration spreads, the vessel may be opened and hæmorrhage occur. In this case also the artery must be tied.

ARTESIAN WELL. A description of well in which the water is obtained by means of a hole bored through an upper impermeable stratum to an underlying stratum, of a permeable character charged with water, and occupying a species of basin-shaped depression, in a still lower impermeable stratum; and also under such conditions of hydrostatic pressure upon the waters contained in the permeable stratum, as to cause them to flow over the surface of the ground at the point of outlet. The name is derived from the fact that wells of this description were first known, in north-western Europe, in the province of the Artois in France, where this method of obtaining water has been practised from a very early period. Properly speaking, an Artesian well is one in which the water from the lower stratum rises *above* the surface of the superincumbent impermeable stratum; but by extension the phrase has been applied of late years to any well in which water is obtained by means of a boring through which the waters of a lower stratum are enabled to rise sufficiently near to the surface to allow of their being economically used. It will be seen hereafter that in many instances borings, which were originally strictly Artesian, have at a later period lost the characteristic property of yielding waters flowing *over* the surface, so that in fact the logical correctness of the name as applied to a particular well may very often depend upon accidental conditions.

In order to secure, originally, the condition that the waters of an Artesian well should thus flow over the surface, it is necessary that the outcrop of the permeable stratum, from which the supply is derived, should be situated at a higher level than that of the edge of the overlapping impermeable stratum. In such cases, the water falling upon the exposed edges of the former, passes under the latter, until it meets with an inferior retentive stratum; and then if it cannot find, or make to itself an outlet, it will follow the surface of the impermeable, upholding stratum, in strict accordance with the laws which regulate the flow of water above ground. If, under these circumstances, an opening should be made through the overlying impermeable stratum, the water will rise to a height corresponding with the level at which it passed under the last-named impermeable stratum; excepting in so far as it may be affected by the friction it meets with in its traject, or by the existence of any natural overflows, created by the interruption of the containing basin; provided always that there should not exist any disturbance of the lower retentive strata of a nature to place the water-bearing stratum in contact with a still lower one which should not have any communication with the surface. The facts, and the theoretical reasoning, published with respect to the well of Grenelle, so strikingly illustrate the philosophy of similar operations, that a short account of it is subjoined.

Numerous wells had been sunk in the neighbourhood of Paris, and also, it may be added, near London, in which a supply of water was obtained from the permeable sand beds situated immediately above the chalk, and covered by the impermeable tertiary strata. At Grenelle, however, it was known, by experiment, that the permeable strata of the other parts of the basin were replaced by marls and clays, which intercepted the passage of the water; and therefore M. Mulot, the engineer of the well, supported by the theoretical reasoning, and by the authority of Messrs. Arago and Walferdin, resolved to seek a supply of water by boring through the chalk into the subcretaceous strata, which were believed to form a continous basin under Paris. At Elbœuf and at Rouen the chalk had actually been traversed, and the water had risen at the former locality to a height of 82 feet above the surface of the ground, or 109 feet above the level of the sea. M. Mulot thence concluded that as the surface of the ground at Grenelle was about 104 feet above the level of the sea, and was nearer the inland outcrop of the water-bearing subcretaceous strata, the water furnished by them would there flow over the surface. Messrs. Arago and Walferdin, in fact, found that the level of the lowest point of the valley of the Seine, in its course above the lower greensand formations, was situated at Lusigny, near Troyes, where the surface of the land was nearly 300 feet above the level of the plain of Grenelle; and they inferred from this fact that not only would the water overflow the borehole, but that it would also rise to a very considerable height above the ground. The great Artesian boring of Grenelle was commenced upon faith in this reasoning; and after eight years of indefatigable labour, in spite of all the accidents of the undertaking, and the sneers of the incredulous, the efforts of M. Mulot were crowned with signal success. After traversing the series of beds described below, a supply of water equal to about 800,000 gallons per diem was obtained from a depth of 1802 feet from the surface, or from a depth of about 1698 feet below the level of the sea; and this water rose to the level of 122 feet above the ground at Grenelle.

Before this result had been obtained, M. Walferdin made a series of observations upon the increase of temperature observable in excavations made in the neighbourhood of Paris; and he there found that the mean temperature of the surface being 51°·34, the temperature below the surface became constant at a depth of 94 feet below that level, and that it there invariably marked 53°·06. In the boring itself the thermometer marked, in the chalk, at a depth of 1319 feet from the surface, 76°·3; and in the gault, at a depth of 1657 feet, it marked 79°·61; thus showing that in the distance of 1553 feet below the line of constant temperature, the total increase of temperature was 26°·55, or about 1°·7 for every succeeding 100 feet. According to this law of increase of temperature, the water at the depth of 1802 feet below the surface ought to have risen with a temperature of 81°·96 nearly; and as they are stated to rise actually at the temperature of 81°·81, they must be considered to confirm, in a very striking manner, the theoretical reasoning of M. Walferdin. It may be added that the waters thus obtained are remarkably pure and soft, and that they are used for the municipal service of Paris. The bore-hole appears, however, to be exposed to occasional stoppages by the rising of sand.

The brilliant success of this boring at Paris brought Artesian wells into fashion, and a number of works of the same description were undertaken in various parts of Europe, within a very short period of the completion of the Grenelle well. Amongst the most important of these were the borings undertaken in the Rhenish provinces for bringing to the surface the waters of the brine springs of that district, some of which even exceeded the depth of 2400 feet from the surface. But no new phenomena of the subterranean strata were observed in these cases; nor was any doubt thrown upon the universal application of the laws of underground waters observed to prevail under Paris, till the result of some Artesian borings, in the neighbourhood of Tours, showed that it was impossible, *à priori*, to state infallibly the conditions which would prevail at great depths. M. Degoussée mentions in his 'Guide du Sondeur,' Paris, 8vo, 1847, that he himself had executed no less than sixteen deep borings in the Département de l'Indre et Loire, of which ten are in the town of Tours and six in its neighbourhood, and presented an average depth of about 500 feet. Two of these borings were, however, unsuccessful; and it appears that the conditions under which they occurred, with respect to the great water courses of the district, were such that it became necessary to suppose that the underground course of the waters was interrupted by means of a fault, or of an upheaval. At Calais, the results obtained by the great Artesian well there sunk were even more striking than those obtained near Tours; for after having in this case passed through the drift above the chalk, the chalk itself, and the whole of the subcretaceous strata, the boring was continued *in the transition rocks*, until it had attained a total depth from the surface of about 1150 feet. It will be necessary hereafter to refer to this well, and to the abnormal state of the geological formations under this district.

Very shortly after the completion of the Artesian well of Grenelle some operations of the same description were undertaken in England, of which the wells at Chichester and at Southampton were perhaps the most important. The former well was carried through the strata of the great Hampshire tertiary basin, then through the chalk, chalk-marl, and upper greensand, wherein it stopped at a depth of 1054 feet from the surface of the ground. Very little water was obtained from this boring; and, indeed, the low temperature at which the water stood in the well, led to the inference that the supply could not have come from the lowest level thus attained. The Southampton well was carried through the tertiary beds of the same Hampshire basin as had been traversed at Chichester; and in this case the total thickness of the series was not less than 434 feet. The boring was then carried through the upper and lower chalks, which here presented a thickness of 851 feet; and was finally abandoned in the chalk-marl, at a total depth from the surface of 1317 feet, without securing any valuable supply of water. A great number of Artesian wells had in the meantime been sunk in the tertiary basins of both London and Hampshire, and the drain thus established upon the subterranean watercourses of those formations was so great, that the waters which originally had flown over the surface of the ground, were no longer able to reach that height; and it became evident that the demand upon these water-bearing strata was rapidly exceeding the supply. Under these circumstances the Hampstead and Highgate Water Works Company resolved to renew under London the attempt which had been abandoned at Southampton; and their advisers argued that, inasmuch as the outcrop of the subcretaceous formations was continuous around the margin of the cretaceous basin surrounding and underlying the London tertiaries, excepting on the eastern border, those subcretaceous strata would be found under London just as they had been actually found at Paris.

This reasoning proved to be correct so far as the chalk-marl, the upper greensand, and the gault were concerned; but when those formations had been traversed (to a depth of 1113¼ feet) the boring tools, instead of entering upon the lower greensand, which theoretically had been expected, entered upon and traversed to a total depth of 1302 feet, a series of marls, clays, and sandstones, which appear in all probability to belong to the new red sandstone series: all the intermediate strata being absent.

The interruption in the series of the subterranean strata at Highgate corresponded in so very marked a manner with the analogous interruption previously observed at Calais, that geologists were forced to admit that their theoretical reasoning with respect to such subterranean strata could only present a character of certainty in so far as it enabled them to foretell what formations *would not* be found in any place, whilst it afforded no guarantee as to what *would* be found. In other words, the lesson derived from these two wells was, that the first attempts to secure a supply of water by means of an Artesian boring to a deep-seated, and hitherto untried, stratum were exposed to great dangers and difficulties, with respect to which the ordinary hypothetical reasoning possessed no character of certainty. Subsequently, the result of the Artesian boring, as it was commonly, but somewhat incorrectly called, at Harwich, added to the point of this lesson; for after traversing the tertiaries, the chalk, chalk-marl, upper greensand, and gault, the boring tools came, as at Calais, upon the transition rocks of a very early geological period, at a total depth of about 1200 feet from the surface. This result was, perhaps, the more remarkable from the fact that a successful boring had previously been made at Stowmarket, within a comparatively speaking short distance from Harwich, in which the lower greensand was found to occur in the position it might have been expected to have occupied in the ordinary geological order. More latterly still a very successful Artesian boring has been executed at Ostend, where a supply of water has been obtained, but only from the lower tertiaries, without traversing the chalk, at a depth of about 553 feet from the surface of the ground.

It would appear from these facts, and from the very remarkable success which has attended the efforts of the French military engineers to obtain water in the Desert of Sahara, that in all cases where the continuity of the subterranean water-bearing stratum is known to exist, Artesian wells may advantageously be resorted to, provided the quantity of water taken from them be not very considerable. From the experience obtained near Paris, Tours, and London, however, it would appear that the supply so to be obtained is very limited; and whenever the demand sensibly approaches the subterranean supply, the first effect produced is to lower the level of the water line, and thus very frequently to destroy the true Artesian character of the wells. In the neighbourhood of Tottenham, for instance, the water now hardly rises to the surface of the ground in some wells where formerly it overflowed.

The operation of boring for Artesian wells is effected usually by means of wrought-iron rods, of about 20 feet long each; the upper end of the first rod having a hook, by means of which it is suspended to the lever communicating to the system the necessary percussive motion, and the lower ends of all the rods bearing a he-screw fitting into the socket of the she-screw on the head of the lower ones. Below the suspending hook there is an eye intended to receive a hand lever, by means of which the workmen give, when required, a rotary motion. In traversing soft materials, such as chalk, clay, fine sand, &c., a mere rotary motion will suffice to ensure the descent of the boring tool carried by the lowest rod; and this tool, it must be observed, is modified so as to suit the various descriptions of soil. But in traversing rock, or hard formations, it is necessary to comminute the latter before the scoops can remove the materials; and this object is effected by raising, and then suddenly letting fall, the chisel, or cutting tool, which will of course descend with a force proportionate to its own weight, and the distance it has travelled. Very great precautions are necessary to guard against the rupture of the rods when the depth is great; and a number of ingenious contrivances have been introduced by MM. Degoussée and Œuyenhausen for the purpose of diminishing the weight thus cast upon the cutting tool, descriptions and illustrations of which will be found in Degoussée's 'Guide du Sondeur;' Burat's 'Géologie appliquée à la recherche des Minéraux utiles;' and to a 'Treatise on Well-digging and Boring,' in Mr. Weale's Rudimentary series. Of late years also M. Kind, a German engineer of considerable eminence, has introduced a modification of the boring tools to be used in deep wells, of which a detailed description will be found in the 'Proceedings of the Institution of Mechanical Engineers,' for July, 1854: and it appears from the experience obtained in several cases that the changes thus suggested have materially diminished the danger attending the rupture of the rods in consequence of their great weight, and of the vibrations to which they are usually exposed. The difficulties thus overcome are, however, very far from being the only important ones attached to this class of operations; for in the case of the boring now in progress, under the orders of M. Kind himself, at Passy, the advance of the work has been seriously impeded by the collapsing of the tubes, through the pressure of the running sands traversed. A similar accident has likewise taken place at Ostend; and even in the case of the celebrated well of Grenelle the supply of water, or the efficiency of the well, is at times seriously affected by the movements of the finer particles of the permeable water-bearing stratum, to such an extent indeed as from time to time to render it necessary to interrupt the distribution of the water in order to clean the tubes. In such cases as those in which the boring is originally carried through strata likely to yield waters of inferior or objectionable quality, as in marsh lands, or in the neighbourhood of the sea, special precautions are required to keep out those waters; and it is customary to employ in such cases cast-iron pipes. In traversing still deeper strata furnishing waters which it may be necessary to exclude, wrought-iron, or even copper pipes, are used. The mode in which these details are executed has the greatest influence upon the success of the operations, and they require a very extensive practical acquaintance with the various conditions of the loose strata, which so strangely modify the resistance to be dealt with. On this score also the boring of Artesian wells is strictly speaking an empirical art, just as it is on the score of the uncertainty with respect to the continuity of the underground strata; and it is for these reasons that the experience of an intelligent, practical, well-borer is a surer guide in such undertakings than any mere abstract philosophical reasoning.

Notwithstanding the disappointment encountered in the above cited cases of the Southampton, Calais, Highgate, and Harwich wells, which were undertaken mainly upon the recommendations of theoretical geologists, the reader who would become acquainted with the general conditions affecting the supply of Artesian wells must still consult the works of that class of writers. The most reliable information upon the subject is to be found, in addition to the works already mentioned, in Héricart de Thury's 'Considérations sur la Cause du Jallissement des Eaux des Puits forés,' Paris, 1829; Buckland's 'Bridgewater Treatise on Geology and Mineralogy,' London, 1837; and Prestwich's treatise 'On the Water-bearing Strata of London,' London, 1851. Delabeche's 'Geological Observer' contains some valuable remarks upon the subject; and the treatise inserted by M. Arago in the 'Annuaire du Bureau des Longitudes,' for 1835, may still be referred to with advantage.

ARTHANITIN (Cyclamin). A non-azotised crystalline body, extracted from the root of the *Cyclamen Europæum*. Its taste is bitter and astringent. It requires 500 parts of water for solution, is insoluble in ether, but dissolves easily in alcohol. Administered internally, it acts as a purgative and emetic. Its composition is unknown.

ARTHRITIS. [Gout.]

ARTICLE, the name given by modern grammarians to the two little adjectives *the* and *an* in the English language, and to words of like import in other modern languages, the former being called the definite, the latter the indefinite article. We do not attempt a more philosophical definition, because the separation of these words from the other adjectives of language, whether pronouns or not, appears to depend upon no very accurate principle; and the distribution of the parts of speech would perhaps not be the less philosophical, if the so-called articles were restored to their proper place. The indefinite article *an* is only a corruption of the adjective *one*, or, as our ancestors wrote it, *ane*; and *a* is a still more violent corruption of the same word. Thus in German *ein* is at once equivalent to our *one* and to *an*. In the same way the French *un*, Italian *uno*, Spanish *uno*, &c., are evidently derived from the Latin *unus*. On the other hand, the definite article will appear, on the slightest consideration, to be a corrupted demonstrative pronoun. The term article or αρθρον (a joint) was invented by the Greek grammarians, but as used by them it is only applied to the definite article, and also to what, by modern grammarians, is called emphatically the relative (who). Nor is there any inconsistency in applying the same term to these two notions, which will be found on examination to have a common origin. The element το (*to*) of the Greek language, corresponding in power to our word *this*, was employed perhaps originally to denote a physical object pointed out at the time by some action of the body; secondly, to an object mentioned just before, and thus mentally present both to speaker and hearer; or, lastly, to an object forthwith to be brought before the hearer's mind. In the second case we are likely to have a repetition of the defining particle, as: "I gave you *the* book *which* you asked for," or, what is equally good, except in rhythm, "I gave you *that* book *that* you asked for." It was from the contemplation of such a sentence as this that the Greeks considered the pair of words as performing the office of joints which connect the two propositions together; and to distinguish the one article from the other, that which precedes the noun (the) was called the *prepositive* article, and that which follows it, namely, the relative, the *postpositive* article. The qualifying terms are perhaps not very well chosen, inasmuch as the relative clause, frequently in the ancient languages, and sometimes even in English, precedes; but undoubtedly the term article is very expressive of these relative particles, which in all cases, or nearly so, do perform the duty of connecting two propositions together; and hence we ought not to be surprised that a large proportion of the conjunctions have their origin in the relatives or demonstratives. But the repetition of the defining, demonstrative, or relative particle is no way necessary. Whether we say "I gave you that book" (pointing to it), or, "You asked for a book that (or that book) I gave you," or, lastly, "I gave you that book you asked for," the word *that* performs in all cases the same duty. The two ideas thus logically connected in the expression—"I gave you the book that or which you asked for," are—"You asked for the book: I gave you the book." It is only a luxury in language to vary the forms according to the mere place in a sentence that a word may occupy; and if, in the more polished forms of the Greek language, we find the demonstrative, the definite article, and the relative distinguished, yet they are all evidently derived from a common parent, το, and its dialectic varieties. In Homer, the article, so-called, has still the power of a demonstrative; in Herodotus, the same element performs at times all the three offices. As we descend chronologically we find the tragedians still confounding the diverging forms of the relative and article, and even in certain phrases, retained by the later writers, traces of the same confusion arising from a common origin were yet to be seen. Matthiæ in his 'Grammar' has so fully acknowledged this triple power of the Greek pronoun, that he treats of the article under the three heads—1. of the article; 2. of the article as a pronoun (he means a demonstrative pronoun); 3. of the article for the pronoun relative.

The Latin language had but an imperfect definite article in its pronouns, *hic, ille, is*; but besides these we find the relative at times employed where the English idiom at least requires the demonstrative *this*; and what is called the conjunction *quod* (that), like the corresponding Greek ὅτι, or French *que*, has the form of a relative, and the meaning of a demonstrative. To trace the same analogy in the Teutonic languages, the German *der*, of which *de* only is radical, is at once demonstrative, relative, and definite article. So completely does the German agree with the Greek, that, when *der* threw off much of its demonstrative power to play the part of the mere article, a kind of doubled form, *dieser*, was adopted for the pure demonstrative, on the same principle of formation as οὗτος, from ὅς, with the same meaning in Greek. And lastly, the English philologist will find the same threefold power among the derivatives from the English allied root, *the*, namely, among the forms *this, that, then, than* (compare the Latin *quam*), *there, thence, the*, &c. The form *that* is still retained, as was before observed, with the power of the relative; but in the older writers, as Chaucer, *there, thence*, &c., were freely used, where we now only employ, *where, whence*, &c.

Horne Tooke, whose views of etymology were neither extensive nor accurate, has fancied that the English article *the* is the imperative of an Anglo-Saxon verb ðean, *to take*. ('Diversions of Purley,' Taylor's edition, ii. 63.) We need not repeat that it is allied to the German *der*, or rather the Dutch *de*, for the *r* is merely the characteristic of a masculine nominative, to the Gothic *sa* or *tha*, and through these to the Greek element *τό*, a form which actually occurs in the English *to-day* (ho-die), for which provincial dialects sometimes substitute *the-day*, thus testifying in favour of the theory; and no etymology for the English article will be satisfactory which does not equally apply to all these languages. In the same way the definite articles of the modern languages derived from the Latin are all referable to the Latin demonstrative *ille, illa*, &c. [Relative; Pronoun Demonstrative.]

ARTICLES OF FAITH. [Confessions.]

ARTICLES OF THE PEACE, a term applied to a recognizance or obligation to the crown, entered on record, and taken in some court by some judicial officer, whereby the parties acknowledge themselves to be indebted to the crown in the sum required, with condition to be void and of none effect if the party shall appear in court on such a day, and in the mean time shall keep the peace. (Blackst., *Comm.*, iv. ch. 18.)

ARTICLES OF WAR. [Mutiny Act.]

ARTICULATION. [Voice.]

ARTIFICIAL FLOWERS. Few employments of a mechanical or manipulative nature are more beautiful in their results than the production of artificial or imitative flowers. Nothing can well exceed the faithfulness of these imitations; every petal, leaf, and bud is imitated with an accuracy which must have required long observation and much ingenuity on the part of those who have practised this art.

The petals of flowers are imitated by ribbons, feathers, silk-worm cocoons, cambric, taffeta, velvet, or thin laminæ of whalebone shaped and coloured for the purpose. The stems are mostly formed of wires, wrapped round with paper, silk, or some other material of the requisite colour. The leaves and petals are mostly cut and embossed by stamping with dies having sharp cutting edges, and are united by means of wires and paste or cement. The modes of colouring are various. Seeds and similar objects, and small fruits, such as currants, are imitated by wax, glass, and other substances. Very beautiful imitations of some plants are made with wax, rice-paper, and shells. Besides the above materials, flowers are occasionally imitated in ebony, maple, box, satinwood, clove, nutmeg, pimento, jet, ivory, coral, pearl, sea-weed, and hair.

This manufacture is generally carried on in private houses, where a large number of persons (mostly females) work together, each taking certain departments, according to the principle of the division of labour; and the whole product is then sold to wholesale dealers, who supply the retail shops.

The French are especially distinguished in this art; all their delicacy of taste is brought to bear upon it. France sells annually to the extent of a million francs (40,000*l.*) to the foreigner; and England, with the United States, purchases more than half this amount.

We will take a rose, as a specimen of French imitative manufacture. The petals, the leaves, the calyx, the buds, the stamens, the stalk—all require distinct processes. First, for the petals. These are made of the finest cambric, which is cut out with punches, there being as many different sized punches as there are different sizes in the petals of a rose. Each petal, being held by pincers at the extreme end, is dipped into a carmine dye; then dipped into water to soften the tint at the edges; then touched with a brush to deepen the tint near the centre; and any little variegated spots, or even blemishes, are imitated by tinting with a brush. Next, for the leaves. These are made of Florence sarcenet, which is dyed to the proper colour, and stretched while wet that it may dry out perfectly smooth. The glazed surface of the leaf is imitated by coating the sarcenet with thin gum-water; while the velvety texture of the under surface is imitated either by a wash of coloured starch-water or by a layer of flock or cloth powder, such as is used in making flock paper-hangings. To imitate the ribs which form such a peculiar and beautiful characteristic of the leaves, several leaves, placed one upon another, are pressed between gaufroirs or goffering-irons, cut with the required indentations. Then we have the leaflets which form the calyx; the sarcenet for these is stiffened with starch-water while yet wet from the dyeing, and when dry the material is cut to the proper size and shape by punches. The buds are made of sarcenet or of kid, dyed or painted according to circumstances; they are swelled out to the proper shape by a stuffing of cotton, gummed flax, or crumb of bread, and are tied with silk at the end of thin iron wires. The stamens are made of silk, fixed at the ends of brass wires, and so shaped that the wire shall imitate the filament and the silk the anther; the silk anther, being dipped into a glutinous liquid, is made to retain some very small seeds which imitate the pollen. Lastly comes the building-up of the delicate structure: the stalk is made of iron wire, coated with cotton and green paper, and around this stalk are grouped and fastened the several parts which together form the imitative rose.

ARTIFICIAL FUEL. Some of the compositions recently introduced as substitutes for coal will be noticed under FUEL.

ARTIFICIAL HORIZON is generally a cylindrical cup, about three inches in diameter, or a rectangular trough, either of them about half an inch deep, and containing quicksilver. A circular plate of glass, whose surfaces should be accurately parallel to one another, is laid on the surface of the quicksilver in the cylindrical cup, but the trough is usually covered by a roof with two inclined planes, each of which is a frame carrying a plate of glass with parallel surfaces. By these means the wind is prevented from agitating the fluid.

The surface of the quicksilver being considered as a plane perpendicular to a diameter of the earth, or rather to a normal, at the place of the observer, is parallel to the rational horizon of that place; and consequently the angle between the plane of the quicksilver and a visual ray from the object to that plane, when corrected for refraction and parallax, is equal to the angular elevation of the object above the true horizon of the place.

Artificial horizons of the kind just mentioned are generally used on land for the purpose of obtaining the altitude of a celestial body by means of an octant, sextant, or reflecting circle, either held in the hands or supported on a small pillar; occasionally also it is employed to obtain the angular elevation of a terrestrial object, as the top of a tower, a mountain, &c. The rays of light from the object, falling on the quicksilver, are reflected from thence to the eye of the observer; and, by the laws of reflexion, the angles made with the reflecting surface by the incident and reflected rays are equal to one another; hence the reflected image of the object appears as much below the horizon, or surface of the quicksilver, as the object itself is above it; and on bringing, by the motion of the index of the sextant, the direct and reflected images to coincide, the angle read on the arc will, the eye being very near the quicksilver, be equal to twice the angle of elevation.

In a regular observatory, the trough containing the quicksilver is, sometimes, several feet long, in order to avoid as much as possible the necessity of changing its place according to the distance of the celestial body from the zenith.

When the atmosphere is very calm, water under a glass-roof may be used instead of quicksilver, but almost the least agitation of the air is sufficient to disturb the reflected image.

On a journey, the conveyance of quicksilver is often inconvenient; and therefore scientific travellers have attempted to use, as an artificial horizon, a circular plate of polished metal, or a dark glass, from which light may be reflected as from a mirror. The horizontality of such an instrument is ascertained by means of a spirit-level placed upon it, and the adjustment is effected by three screws which pass through the frame of the mirror at equal distances from one another.

Since, with the usual reflecting instruments, double altitudes exceeding about 120° cannot be observed, the artificial horizon just described would be useless, if the altitude of the object were greater than 60°; they can however be employed with instruments similar to those invented by Captains Fitzroy and Beechey, by which angles exceeding 180° may be observed.

The artificial horizons permit very accurate observations to be made on land, but it is evident that they cannot be used at sea, even though well suspended in jimbals, on account of the unsteady motion of the ship; and some means of enabling a seaman to observe correctly the altitudes of celestial bodies when the sea-line is invisible, or but faintly seen through the vapours near the horizon, is still a desideratum.

It is known however that when a conical or a cylindrical body, terminating at the lower extremity in a point, is caused to revolve rapidly on its axis, that axis soon takes, and for at least half an hour maintains, a vertical position; and efforts have been made to employ such a body, having a mirror on its upper surface, as an artificial horizon on board a ship. A 'Nautical Top,' as it was called, was proposed by a Mr. Serson, and is described in the 'Philosophical Transactions' for 1750; but, on being tried at sea, its irregularity was found to be great, and the contrivance was abandoned. The late Mr. Troughton however, in 1818, made considerable improvements on the original construction, but his success was not such as to render the machine available. He made the *top* at first cylindrical, but he afterwards gave it the form of a frustrum of a cone; the reflecting plane formed the upper surface, and immediately under this was a stem terminating below in a steel point, which rested on the concave surface of a small steel cup. A rapid motion was communicated to the machine by a series of wheels, of which the first was turned by means of a handle on its circumference.

The only contrivance which appears likely to serve the purpose of an artificial horizon at sea is a spirit-level applied to the face of an octant or sextant; and an instrument of this kind was proposed and executed by Troughton. The spirit-level, in a brass tube, was placed between the index and horizon glasses; and, through a perforation in the tube, the observer could see in the horizon-glass the reflected image of the bubble of air: a line was traced on the horizon-glass, and a contact of the limb, or centre, of the celestial body was to be made on this line at the instant that the latter appeared to bisect the reflected image of the bubble. The arc passed over by the index would then express the altitude of the celestial body above the horizon. Instruments very similar to this have been executed by Mr. Robinson, and, for merely nautical observations, they possess sufficient accuracy; the altitudes obtained with them being within two or three minutes of their true values.

ARTIFICIAL LIMBS, &c. Considerable mechanical ingenuity is displayed in supplying substitutes for limbs or other bodily organs which accident or any other cause has removed.

The art of the dentist, for instance, calls for no small amount of mechanical skill. First, there is the choice of the ivory which, from its colour, texture, and hardness, affords the best imitation of the natural teeth. Then there is the shaping of this ivory to the size and form of the tooth, whether single or double, front or back, upper or under. And lastly there are the remarkable contrivances—aided by golden palates, springs, wires, cement, gutta percha, or other substances—by which the tooth or mouthful of teeth are fixed in their places. Experience seems to show that few kinds of cheapness are so dear as cheap tooth-making: so great are the difficulties in supplying teeth that will readily eat their way through the difficulties presented to them. As for the succedaneums and metallic and other cements for stopping decayed teeth, their merit depends more on the quality of the material than on the mode of using. We see from time to time patents for new contrivances in dental surgery, which involve no small amount of ingenuity. One such was enrolled by Mr. Dinsdale, in which the manufacture of teeth, palates, and gums is described; and there are now many others.

An artificial eye is an example of glass manufacture; the shaping of the glass being much less difficult than the accurate imitation of the cornea and iris by means of pigments and dyes.

All those numerous examples of skill, which may more fittingly be called surgical *operations* than anatomical *contrivances*, we have nothing to do with here; but when a mechanician undertakes to supply a substitute for an arm, a hand, or a leg, we have as much right to claim it as a proof of constructive skill as a loom or a lathe, a plough or a clock. And here we mark how quickly a newly-discovered substance becomes brought within the scope of the operations. Is it caoutchouc? Then will the artificial leg-maker find out where to use it with advantage. Is it gutta percha? Then will he soon see where the combined elasticity and toughness of that remarkable substance are likely to be valuable. Accordingly, we find that many different materials are employed, either to give shape to the artificial hand, arm, or leg, or to give smoothness and softness to the surface, or to form the joints for the requisite movements. Wood, leather, caoutchouc, gutta percha, cork, iron levers, steel springs—all are employed; and much ingenuity is displayed in arranging the materials.

Sir George Cayley, who exhibited much inventive talent in various mechanical contrivances, made many trials to produce an artificial hand which should be less costly than those ordinarily constructed. He made the 'Mechanics' Magazine' the medium of communicating his experience in this matter. His first attempt was in 1845. The son of one of his tenants having lost a hand by accident, Sir George contrived a substitute which in many ways lessened the severity of the privation. The movements of this instrument are derived from the stump; a light frame-work fixes the apparatus to the upper part of the arm, and a lever connects this frame-work with the artificial hand. The arm is placed within padded rings of metal, which are connected by two long steel bars hinged at the elbow. When the wearer moves his arm by the usual action of the elbow-joint, he shifts a small metal bar near the wrist of the machine, which works two cog-wheels acting on each other; and these cog-wheels bring two steel springs together so as to enable them to grasp an object something in the manner of a thumb and fore-finger. The wheels and springs may either be left exposed, in the metallic state, or may be padded so as to represent a thumb and finger. It was found that although this artificial hand could be turned round a little way, it could not be turned so much as a quarter of a circle from its horizontal towards a perpendicular grasp; and there was, at the same time, no movement equivalent to the usual bending of the wrist, which gives so great a variety of positions to the natural hand. He therefore contrived a new arrangement of mechanism at the wrist, so as to superadd these two movements to those before possessed by the apparatus; this involved an increase of rather delicate mechanism.

At one of the soirées given by the President of the Royal Society in 1845, the boy for whom Sir George Cayley made the artificial hand was introduced, and Prince Albert "shook" him by his mechanical appendage. The hand had only one finger worked by the mechanism; but there were the proper number of cork fingers united side by side, and fixed to one broad thin steel plate, jointed, and covered with continuous leather, stitched down to mark the distinction of the fingers under it. But where a more expensive apparatus can be afforded, and the appearance of having a real hand is sought for, the thin steel plate can be separated into digits, though united at the base as in a common hand, and jointed at the proper places in due proportion to each finger.

In another form of artificial hand, made by Sir G. Cayley, in 1847, there is a case or sheath, into which the stump of the arm is introduced. A spiral spring is fixed at one end to this sheath, and at the other to a bent lever; while the middle of the lever is connected with the mechanism of rods which move the artificial thumb and fingers. In this arrangement, the wearer uses his sound hand to work his artificial hand. He presses a little button which is connected with the bent lever; by pressing this towards the wrist, the fingers and thumb open to receive any object they may be intended to grasp; and when this pressure from the other hand is taken off, the grasp takes effect, without further effort, till released by a contrary movement. The mechanism is very simple, and is attached wholly to the lower arm, near the stump. But as the sound hand must be taken from anything else it has to perform, at the time the artificial hand is thus put to work; and as it may on other accounts be inconvenient to work the apparatus in this way,—Sir George invented a very ingenious means of working the hand by the movement of the upper arm or shoulder-joint.

One of Sir George Cayley's contrivances, made by Mr. Buckingham, was shown at the Great Exhibition of 1851; as was also an ingenious artificial hand invented by Major Little of Woolwich.

M. Magendie described to the Paris Academy of Sciences, in 1845, an artificial arm, invented by M. Van Petersen. A sort of stays are fixed round the breast of the person; and from these are brought cords made of catgut, which act upon the articulations, according to the motion given to the natural stump. The apparatus was found to be very effective. It was tried (among other patients) on an invalid soldier, who had lost both arms in the wars of the empire, retaining only the stumps. With the aid of two of the artificial arms, he was able to perform many of the functions which had hitherto been performed for him. M. Magendie considered this contrivance to be the best substitute for a natural arm which had till then been introduced.

A curious example of mechanical anatomy is exhibited in Count Dunin's 'Model Man,' first made public in this country in 1851. It is intended to illustrate the different proportions of the human figure, and admits of being expanded from the size of the Apollo Belvidere to that of a colossal statue. The external part of the figure consists of a series of steel and copper plates sliding upon each other, and kept in contact by screws, nuts, and spiral springs. Attached to these plates, and within the figure, are metal slides, having projecting pins at their extremities; these pins are inserted in curved grooves cut in circular steel plates—the curvature of the grooves being so arranged that when the steel plates are put in revolution by a train of wheels and screws, the slides belonging to each particular part of the figure are expanded or contracted in correct proportion. The elongation of the figure is accomplished either by sliding metal tubes, provided with racks, and acted upon by a combination of wheels, or by screws and slides, as found most applicable for each particular part. Besides these symmetrical adjustments, each part of the figure has an independent and separate adjustment, by which it may be thrown out of symmetry, and made to represent the deformities or peculiarities of form in any individual. So intricate is the mechanism to produce all these movements, that the figure comprises 7000 plates, springs, slides, wheels, tubes, nuts, screws, and other pieces of metal. This remarkable piece of mechanism could easily be made applicable in the artist's studio; but the inventor seems to have had more especially in view the use of the model to assist in measuring and making clothes for large numbers of men, such as an army—the different sizes and shapes of the men being imitated by the model.

ARTIFICIAL STONE. [CEMENT.]

ARTILLERY, a word believed to be of French origin. Menage derives it from the old word *artiller*, to fortify. Vossius ('De Vitiis Sermonis,' lib. iii. cap. 1) says the ancient word, instead of Artilleria, was *Arcualia*, from *Arcus*, a bow; the earliest military engines of this description having arisen out of improvements upon the bow and arrow. Artillery, in its most general signification, implies all kinds of missiles with the engines used in propelling them. Since the application of gunpowder to projectiles, it has chiefly been confined to large ordnance, or cannon, mortars, howitzers, &c., to which rockets are now to be added, and includes their ammunition, appurtenances, and means of transport, as also the men and officers employed in working them.

It was long after the nations of the east had formed war into a science, that military engines, such as are comprised in the term artillery, were invented. The earliest were, in all probability, those for casting stones of prodigious weight. Of Uzziah (B.C. 1000), 2 Chron. xxvi. 15, it is said, "And he made in Jerusalem engines, invented by cunning men, to be upon the towers and upon the bulwarks, to shoot arrows and great stones withal. And his name spread far abroad; for he was marvellously helped till he was strong."

Among ancient engines of artillery, the *Battering-ram* has been usually included, though it certainly is not embraced in the ordinary or in any other definition of that word. Pliny, whose authority in such a matter is small, says it was invented at the siege of Troy; but Homer makes no mention of it. The first notice of this engine is probably in Ezekiel, where the prophet speaks of a feigned siege of Jerusalem as a sign for the Jews (iv. 2): "set battering rams against it round about;" and again (xxi. 22), "appoint battering-rams against the gate." Ezekiel lived about 590 years B.C. The next mention of the battering-ram is in the Peloponnesian war, B.C. 429 (Thucyd. ii. 76); and we are certain that it was used a century afterwards at the siege of Motya by Dionysius the Elder. The ram was sometimes used, but not commonly, in the middle ages.

The names Balista, or Ballista, and Catapulta, imply a Greek origin. The balista was for throwing stones; the catapulta for propelling darts and arrows. The invention of the latter of these instruments, or rather its re-invention, is ascribed by Pliny (lib. vii. 56) to the Syrians; but Diodorus (lib. xiv.) and Plutarch ('Apophth.,' edit. Wyttenb., 4to, Oxf. i. 533) say they were contrived in Sicily, about the same time with the battering-ram, alluding to a period not earlier than B.C. 300. Ælian ('Var. Hist,' vi. 12) ascribes the invention to Dionysius the Elder himself, in Sicily. The balista is attributed by Pliny to the Phœnicians. Both instruments were unquestionably much used in the Roman times. They are mentioned in Cæsar, Cicero, Livy, Seneca, Tacitus, and other writers, and were employed in great numbers by Titus at the siege of Jerusalem. Two thousand machines for throwing darts and stones were surrendered to the Consul L. M. Censorinus when he marched against Carthage. (Appian, lib. viii., 'De Rebus Punicis,' § 80.) Ammianus and Vegetius are both particular in describing the construction of the balista. Vegetius, who lived in the 4th century, under Valentinian, speaks of balistæ, onagri, scorpiones, arcubalistæ, fustibuli, and fundæ, as engines of artillery (lib. iv. c. 22).

We have no evidence that machines of this description were known in England previous to the arrival of the Normans. According to the testimony of William of Poictou, machines of wood (exclusive of the cross-bow) were used for pouring forth showers of arrows even at the battle of Hastings; so early were they introduced in the Norman time. It is worthy of notice, that among the tenants *in capite* in the Domesday Survey, *balistarii* occur, as well as *arcu-balistarii*. Artillery, however, in the Norman period, was most frequently used in sea-fights, when not only stones and darts were discharged from the machines, but pots of Greek fire, quick-lime, and other combustible materials. Robert of Bruce (in Peter Langtoft's 'Chronicle'), speaking of Richard I.'s wars against the Saracens, says, that in his barges and galleys he had mills, which were turned by the wind, and by force of the sails threw not only fire, but stones which were taken from the Rhine.

It would be tedious to enumerate all the arts and all the machines which were employed in the middle ages in assaulting and defending towns and castles. Indeed, few sieges of great importance occurred without the invention of some new engine. Grose, in the preface to his 'Antiquities of England and Wales,' has given the names and figures of a considerable number. Some of these were distinguished by the appellations balista, catapulta, espringal, trebuchet, mangona, mangonel, bricolla, petrary, matafunda, berfrey, and war-wolf. Père Daniel also mentions a machine called engine-a-virge, used by the English in France, as late as the reign of Charles VII. Of the vast force of these machines surprising stories are related in our chronicles. The engines used by Edward I. at the siege of Stirling Castle in 1303, according to Hemingford, threw stones of 300 pounds weight.

This ancient artillery continued to be used in sieges for a considerable time, in some instances for two centuries, after the invention of gunpowder and cannon. (See Père Daniel, 'Histoire de la Milice Françoise,' tom. i., p. 319.) Greek fire continued also to be employed in war long after the introduction of fire-arms, particularly in the attack and defence of strong places, as at Ypres and Burburgh in France, in 1383. (Walsingh., edit. Camd., pp. 302, 303.)

The invention of gunpowder however by slow degrees brought about a total alteration in the art of war. Colonel Chesney states, in his work 'Observations on Fire-Arms' (published in 1852), that the fact of cannon-balls having been propelled by gunpowder as early as A.D. 1200 in India, is established by the following passage in the Hindoo poet Chosed :—"Oh ! chief of Gaqué, buckle on your armour, and prepare your fire-machines ;" the fire-machines alluded to being described in another passage in the following words :—"that the culivers and cannons made a loud report when they were fired off, and the noise of the ball was heard at a distance of 10 coss, or nearly 1445 yards." There is no reason for believing that this is the first or even an early instance of the use of cannon in the east, where gunpowder had probably been known for a long time, and the mention of the use of incendiary projectiles amongst the natives of China and India at an earlier date is often met with. Colonel Chesney, in the same work, thus proceeds to trace the introduction of artillery into Europe :—"The Moors, according to Condé, used artillery against Zaragossa in 1118 ; and in 1132, a culverin of 4 lbs. calibre, named Salamonica, was made. In 1157, when the Spaniards took Niebla, the Moors defended themselves by machines which threw darts and stones by means of fire ; and in 1157, Abd'almumen, the Moorish king, captured Mohadia, a fortified city near Bona, from the Sicilians, by the same means. In 1280 artillery was used against Cordova, and in 1306 or 1308 Ferdinand IV. took Gibraltar from the Moors by means of artillery. Ibn Nasan ben Bia, of Grenada, mentions that guns were adopted from the Moors and used in Spain in the 12th century, and that balls of iron were thrown by means of fire in 1331."

Barbour, in his 'Metrical Life of Robert Bruce,' tells us that cannon (which he calls "crakys of war") were used by Edward III. in his first campaign against the Scots in 1327. Du Cange, in the article 'Bombarda,' shows that the French used cannon at the siege of Puy Guillaume in 1338 ; and that Edward III. used them at the battle of Crecy, as well as at the siege of Calais in 1346, seems agreed. Four pieces planted on a little hill at the battle of Crecy did great execution among the French troops, and having been before unheard of in France, contributed as much by the surprise as the slaughter to the success of the day. (See Rapin, vol. i., p. 425.) This seems to have been denied by some authors, in consequence of the supposed silence of Froissart. The Emperor Louis Napoleon, however, in his work on Artillery, alludes to a passage in a manuscript of Froissart, preserved in the library at Amiens, which proves that he was neither ignorant nor silent of the fact. Another ancient manuscript mentions the pay of the artillerymen that Edward III. had in 1346, when he landed at Calais, "masons, carpenters, engineers, &c., gunners and artillerymen, some at 1*s.*, 10*d.*, 6*d.*, and 3*d.* per diem." It is clear, however, that if cannon were used by the French at Puy Guillaume in 1338, they could not have been the absolute novelty asserted at Crecy in 1346. By degrees, the use of cannon became more and more common. Petrarch, in his 'Dialogues' on the Remedies of Good and Bad Fortune, written in 1358, describes cannon as no longer rare, or as viewed with astonishment and admiration.

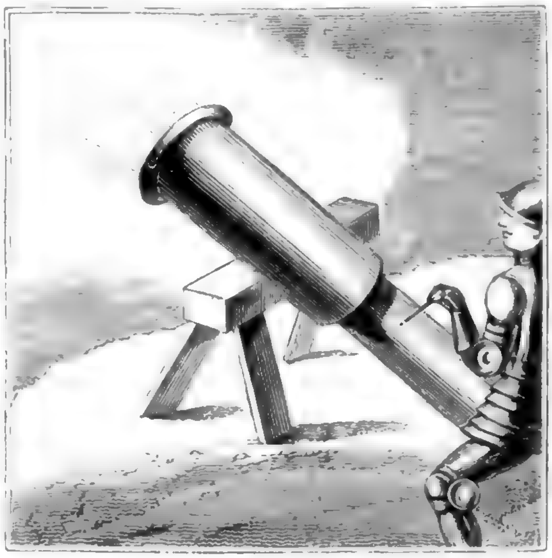
Cannon, or, as they were then called, bombards, were the most ancient fire-arms. The first cannon were clumsy and ill-contrived, wider at the mouth than at the chamber, and so like a mortar that Dr. Henry supposed the idea of them might have been suggested by that in which Schwartz, a chemist of the beginning of the 14th century, who is said by the Germans to have discovered gunpowder, pounded his materials. They were all made of iron, without any mixture of other metals ; and consisted usually of bars or pieces of iron fitted together lengthways, and hooped with iron rings. Some of them were too long, and others of them too short. In a word, the art of making cannon was still imperfect.

Both gunpowder and cannon were made in England in the 14th century. This appears from a commission given to Sir Thomas Norwich by Richard II., in 1378, to buy two great and two small cannon in London, or in any other place, and also to buy certain quantities of saltpetre, sulphur, and charcoal, for making gunpowder. (Rym. 'Fœd.' tom. vii. p. 187.) From the same commission, as well as from other evidence, it appears that cannon-balls were at first made of stone ; for the same person is therein commanded to purchase six hundred balls of stone, for cannon, and for other engines.

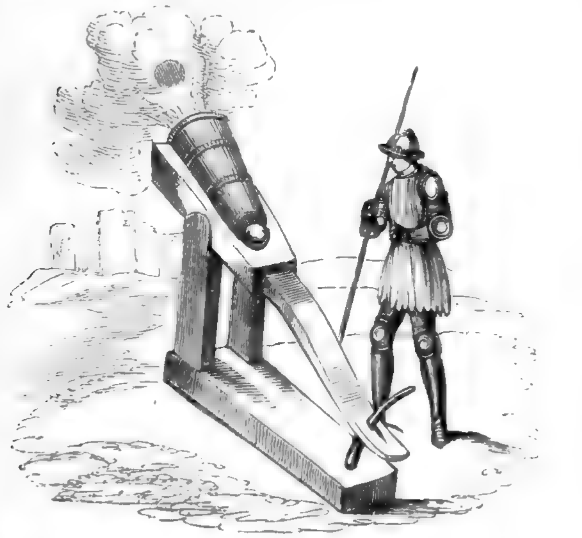
Besides great guns, which are still named cannon, a smaller kind of ordnance called *hand-cannon* came into use at this period. They were so small and light that one of them was carried by two men, and fired from a rest fixed in the ground. (Père Daniel, tom. i. lib. vi. p. 321.) The 400 cannon, or the greater part of them, with which an English army besieged St. Malo, in 1378, mentioned by Froissart (Lord Berner's Transl. chap. cccxxxii.), must have been of this kind : though Dr. Henry conjectures that these hand-cannon were first brought into Britain by the Flemings who accompanied Edward IV. in his return to England in 1471. The Scots, he adds, had a kind of artillery at this period peculiar to themselves, called *carts of war*. They are thus described in an Act of Parliament in 1456 : "It is thocht speidfull, that the king mak requeist to certain of the great barrons of the land that are of ony myght, to mak carts of weir, and in ilk cart twa gunnis, and ilk ane to have twa chalmers, with the remanent of the graith that effeirs thereto, and an cunnand man to shute thame." By another Act, in 1471, the prelates and barons are commanded to provide such carts of war against their old enemies the English. (Henry, 'Hist. Brit.' from Black Acts, James II. act 52, James III. act 55.)

The instruments of artillery of the middle of the 15th century, though all called by the general name of cannon, were of very different kinds, shapes, and sizes, and distinguished from each other by particular names. The letters which Edward IV. addressed to different persons in 1481, for the resistance to invasion from Scotland, speak of "bumbardos, canones, culverynes, fowelers, serpentynes, et alios canones quoscumque, ac pulveres sulphureos, saltpetre, petras, ferrum, plumbum, et omnimodas alias stuffuras pro eisdem canonibus necessarias et oportunas." (Rym. 'Fœd.' tom. xii. p. 140.)

A French translation of 'Quintus Curtius' by Vasqua de Lucene, a Portuguese, written in 1468, preserved in the British Museum, and which formerly belonged to Philip de Cluys, a Knight and Commander of the order of St. John of Jerusalem, has one or two early representations of the larger sort of cannon, which are here exhibited.



Monstrelet illustrates the clumsy form as well as the clumsy management of ancient cannon. Under the year 1459 he says, "while King James (of Scotland) was observing the effect of his artillery (at the siege of Roxburgh Castle), one of the rudely contrived cannons of that age, consisting of bars of iron girded with circles of metal, suddenly burst : a fragment struck his thigh, and the great effusion of blood produced a death almost instantaneous. The Earl of Angus, who stood next to James, was wounded." Under 1478 he says, "A great bombard, that had been cast at Tours, was brought to Paris the Monday before Epiphany to be proved, and was for this purpose drawn out into the fields in front of the bastile of Saint Anthony. It was pointed towards Charenton, and when first fired threw the ball as far as the gallows on the bridge of Charenton ; but as those present did not think it had discharged all the powder that had been put into the chamber, they ordered it to be recharged, and the chamber perfectly cleaned of all that remained within it, which was done, and an iron ball weighing five hundred weight, put into its mouth, before which stood John Maugué, the founder of it. As the ball rolled down the bombard, by some unknown accident the powder in the chamber took fire before the match was put to it, and by its discharge tore in pieces John Maugué and fourteen other persons, whose heads, legs, arms and bodies were blown into the air. The ball killed a poor innocent bird-catcher



that was attending his nets in the fields, and the bursting of the bombard maimed fifteen or sixteen others, several of whom died; so that by this accident twenty-two or twenty-three persons lost their lives. The remains of John Maugué were collected, put on a bier, and carried to St. Merry for interment; and proclamation was made through the streets of Paris that all people should pray for the soul of John Maugué, who had lost his life in the king's service." (Johnes's 'Monstrelet,' 4to., vol. iv. p. 402-403. In 1477, when Louis XI. made his attack upon different towns of Flanders and Picardy, he ordered bombards of prodigious length and weight to be cast at Paris, Tours, Orleans, and Amiens. His iron bullets were cast at the foundries at Creil, and his stone bullets made at the same time in the quarries near to Peronne.

About the middle of the 14th century, fusible metals were employed, on the continent, in the construction of cannon, especially bronze, which combines suitable tenacity with moderate hardness. Guns were not cast in England till 1521, in the reign of Henry VIII., when brass guns were cast, and iron guns about 1547. Both Henry VII. and Henry VIII. appear to have been very anxious to foster the science of artillery in England, employing a number of Flemish gunners for that purpose. Guns were at this period cast hollow, the bore being formed by a core which was kept suspended in the centre of the hollow mould into which the metal was run, and which formed the cast.

It is probably bronze that Stowe alludes to in a passage of his 'Annals.' He says, "this year, 1535, John Owen began to make brass ordnance, as cannons, culverines, and such like. He was the first Englishman that ever made that kind of artillery in England; his issue of his name and the name of Pitt have continued unto the days of King James most ready and exquisite gun-makers for the general service of the kingdom." A beautiful specimen of this sort of ordnance, cast at Utrecht in 1544, and presented by the States of Holland to Queen Elizabeth, is still preserved at Dover Castle. Other specimens, both English and foreign, a little later in period, may be seen at the Tower of London, and in the Royal Arsenal at Woolwich, as well as in many of the foreign arsenals. The sizes of cannon, generally speaking, in the 16th century, were considerably diminished, and forms of greater elegance were given to their exterior.

Robert Borthwick, an artist in the service of King James IV. of Scotland, had attempted the establishment of a foundry at Edinburgh a short time previously. Some of his guns, which remained in Lesly's time, had this inscription: 'Machina sum Scoto Borthuik fabricata Roberto.'

The largest cast cannon now existing is a brass one at Bejapoor, called Malick é Meidân, 'the lord of the plain;' it was cast in commemoration of the capture of that place by the Emperor Alum Geer, in 1685. Its extreme length is 14 feet 1 inch; the diameter of its bore 2 feet 4 inches. An iron shot for this gun of proper size would weigh 1600 pounds.

For *Mortars* we are indebted to workmen who were employed by Henry VIII., and for cast-iron ordnance to the reign of Edward VI. Under the year 1543, Stowe says, "King Henry, minding wars with France, made great preparation and provision, as well of munitions and artillery, as also of brasse ordnances, amongst which, at that time, by one Peter Bawd, a Frenchman born, a gun-founder, or maker of great ordnance, and one other alien, called Peter Van Collen, a gunsmith, both the king's feed men, who conferring together, devised and caused to be made certain mortar-pieces, being at the mouth from eleven inches to nineteen inches wide; for the use whereof the said Peter and Peter caused to be made certain hollow shot of cast-iron, to be stuffed with fire-work or wild-fire, whereof the bigger sort for the same had screws of iron to receive a match to carry fire kindled, that the fire-work might be set on fire, for to break in small pieces the same hollow shot, whereof the smallest piece hitting any man would kill or spoil him. And after the king's return from Boulogne, the said Peter Bawd by himself, in the first of Edward VI., did also make certain ordnance of cast-iron, of divers sorts and forms, as fawconet, fawkons, minions, sakers, and other pieces. Unto this Bawd, John Johnson, his covenant servant, surviving his master, did likewise make and cast iron ordnance cleaner and to better perfection, to the great use of this land. His son Thomas Johnson is yet living, a special workman. In the year 1595 he made forty-two cast pieces of great ordnance of iron for the Earl of Cumberland, demy cannons, weighing 6000, or three ton the piece." ('Annals,' edit. 1631, p. 584.)

It appears from Sir William Monson's 'Naval Tracts,' that the *Falcon* was a species of ordnance of two inches and a half bore; weight of shot two pounds; that the *Demi-Culverin* was another kind, of four inches bore; weight of the shot nine pounds and a half: and that the *Mynion* was another of three inches and a half bore; weight of the shot four pounds. The *Culverin* was a species of ordnance of five inches and a half bore; weight of the shot seventeen pounds and a half. The *Fowler* is not described by Monson, but is mentioned by Lodge in his 'Illustrations of British History,' vol. i. p. 4, as in use in the time of James I. The *Sacar* or *Saker*, according to Monson, was a piece of ordnance of three inches and a half bore; weight of shot five pounds and a half.

The invention of *Petards* is due to the French civil wars. They were first used by the Huguenots in 1580, at the siege of Cahors in Quercy. (Du Thou, tom. viii. p. 376.) Montelimar and Embrun in Dauphiné were taken by Lesdigecéres in 1585, principally by means of petards. (*Ibid.* tom. ix. pp. 404, 405.) According to Père Daniel (cited in 'L'Art de Verifier les Dates,' tom. i. p. 655), red-hot balls, revived in 1782 at Gibraltar, were used by Marshal Matignon during the siege of La Fère in 1580. But we learn from Elmham's 'Life of Henry V.,' p. 155, that they had an earlier origin. He says, that when an English army, commanded by the Duke of Gloucester, besieged Cherbourg in 1418, the besieged discharged red-hot balls of iron from their cannon ("massas ferreas rotundas, igneis candentes fervoribus a saxivomorum faucibus studuerunt emittere") into the English camp, to burn the huts in which the soldiers were lodged.

The *Howitzer*, an improvement upon the mortar, is said to have been invented by Belidor, and was first used at the siege of Ath in 1697. The *Carronade*, a sort of short cannon, or rather long howitzer, was invented by General Robert Melville, about the year 1779.

Iron Rockets of different sizes, varying in weight from sixteen to more than forty pounds, were invented during the last war by Sir William Congreve, and are now called Congreve Rockets. They were first used at the bombardment of Copenhagen, afterwards against the Boulogne flotilla, then at Flushing, and subsequently at the battle of Leipzig. A rocket establishment now forms a regular branch of the British military service.

It was not till about the beginning of the 18th century that guns were cast solid, as at present. A man of the name of Marity, who had a foundry at Geneva, offered his invention, of boring guns that were cast solid, to the court of France, by whom it was accepted. At Lyon, where he was first established, and afterwards at Strasbourg, he constructed guns on this plan, which were found on trial to be very successful. From Fosbrooke we take the following table of the ordnance used in the time of Elizabeth, and shortly before her reign, and it is surprising to see how little we have changed the calibres or diameter of bore of our guns during this period, exactly three centuries since her accession to the throne.

	Pounder.		Inches.		Pounder.
Cannon Royal	66	Diam. of bore	8½	Answering to our	68 or 8 in. gun.
Cannon Serpentine	53½	,,	7	,,	56
Bastard	41	,,	7	,,	42
Demi Cannon	33	,,	6¾	,,	32
Petro	24	,,	6	,,	24
Culverin	17½	,,	5½	,,	18
Demi Culverin	9½	,,	4	,,	9
Sacker	5½	,,	3½	,,	6

The reason for retaining the old calibres has evidently been, that on the introduction of each improved form of gun, it was made to suit some class of ammunition, already in the service, which would otherwise be wasted.

From that time to the present the form and construction of guns have been gradually improved, both in heavy ordnance and in light or field artillery. Gustavus Adolphus was the first who introduced field artillery; at least, what we understand by that term, namely, artillery that can be moved with ease and rapidity, and accompany, according to its calibre, either cavalry or infantry, in all their movements. In 1631, he won his great victory of Leipzig, principally by his artillery; some of his guns were of a most peculiar construction, an interior metal cylinder strengthened by rope wound round it, and covered with boiled leather. Frederick the Great still further improved field artillery, and under him it was capable of taking part in the most rapid movements.

Artillery, in the present day, has become a most important arm, and has modified the methods of putting the principles of strategy and tactics in execution, though it can never change the principles themselves. This will be at once evident, when we consider that it is essentially offensive, being only used offensively even in defence. It has no power of acting by itself, but, confined solely to reaching distant objects with its projectiles, is employed in the preliminary contest so to break the formation of either the attacking or attacked enemy, that the main power of the army, the infantry, may be able to resist the attack, or successful in their charge. And though the ancients had no such powerful propellent arm, yet their slingers, archers, cross-bow and javelin men were employed with the same object, the range, if we may so express it, being much less and more confined.

Artillery has also given a great advantage to civilised over barbarous nations, the science required in the construction, and the expense in the armament of troops with this powerful arm, having placed the latter wholly at the mercy of the former; reversing the facts of former days, when barbarous nations, constantly trained in war, were more than a match for their more civilised, and thereby more or less effeminate, neighbours. Such was the case in the Western Empire, which soon fell before the hordes of Germany.

The long trains of artillery, with their accompanying carriages for ammunition, &c., cause much greater immobility in modern armies. They cannot perform those rapid evolutions, in sight of an enemy, by which victories were gained in former times. The armies are extended over a much longer front, both to allow room for the artillery, and to avoid the ravages that would be caused by artillery in dense masses. Actions, which formerly could be clearly seen and described, are now confused and hidden by the smoke. The gaining of victories, therefore, depends much more on the genius of the general in a judicious selection and proper disposition of troops on the field of battle. And though the powers of destruction have been much increased, both the numbers and disproportion of the slain in both armies has been much decreased, for battles have been often fought and won where the opponents have hardly come into collision; and when they have, it has only been partial and of short duration, and not the sanguinary hand to hand contest of former times.

Artillery is now divided into two classes, light, or field, and heavy; the former consisting of horse artillery, field batteries, and batteries of reserve and position, which are of an intermediate description; the latter of siege and garrison artillery. Horse artillery is organised with light guns, well horsed, to accompany cavalry in all its movements; the field batteries, with heavier guns, but still able to make rapid movements, on occasion, for concentration, &c., to accompany the infantry; the batteries of position and reserve, with a still heavier description of gun, though intended to accompany an army in the field, are not intended to make rapid movements, but, to a certain extent, remain in the same position during an action, or arm any field-works that may be thrown up. The siege and garrison artillery consist of the heaviest guns for which transport can be provided, or the exigencies of the service may require. The following table, extracted from General Lewis's article on Artillery in the 'R. E. Aide-Mémoire,' with slight alterations, shows the constituent subjects of artillery most concisely stated:—

- Personnel
  - Horse Artillery.
  - Rocket do.
  - Foot do.
    - Field.
    - Garrison.
  - Invalid gunners.
  - Master gunners.
- Materiel.
  - Ordnance
    - Iron
      - Guns.
      - Howitzers.
      - Mortars.
      - Carronades.
    - Brass
      - Field guns.
      - Field howitzers.
      - Mortars.
    - Rocket
      - Field.
      - Heavy.
  - Carriages
    - Travelling
      - Field.
      - Siege.
    - Standing
      - Wood.
      - Iron.
  - Platforms
    - Ground
      - Wood.
      - Stone.
    - Traversing
      - Wood.
      - Iron.
  - Ammunition
    - Powder.
    - Shot and shells.
    - Case or canister, spherical case, grape.
  - Stores in general.

- Instruction
  - Academical for officers.
    - Theoretical
      - Mathematics.
      - Fortification.
      - History and geography.
      - Plan drawing.
      - Landscape drawing.
      - Languages.
    - Practical
      - Drills — both infantry and artillery.
      - Sword exercise.
      - Gun and mortar practice.
      - Repository course.
      - Laboratory course.
      - Foundry, proof, and carriage department—courses.
  - Elementary tactics for non-com. officers and gunners
    - Theoretical
      - A course of elementary instruction in the schools.
    - Practical
      - Infantry drill, and other exercise of arms.
      - Field battery exercise.
      - Gun, mortar, howitzer, and rocket practice.
      - Repository course.
      - Partially laboratory course.

The personnel, in the English army, is formed in one corps, called the Regiment of Royal Artillery, which, however, consists of 14 battalions of 8 companies each, called the Foot Artillery, and a horse brigade of 10 troops, which furnishes the personnel of the horse artillery; the men composing these troops are permanently employed as horse artillery, whilst the companies of foot artillery are sometimes employed in the field batteries, and sometimes in garrison or siege duties; a certain number of men, however, enlisted as drivers, always remain as such.

As experiments are, at the present time, being carried on with a gun of novel construction and great power, invented by Sir W. Armstrong, which will most probably be introduced into the service and cause great alterations, field artillery will be further treated under that head. For the present mode of making CANNON, see that article, and for the theory of artillery see GUNNERY. The size and description of the various guns in the service will be found under ORDNANCE.

ARTILLERY PARK. This term is applied both to the camp of one or more field batteries, and to the enclosure, where, during a siege, the general camp of foot artillery and depôts of guns, matériel, &c., are collected. In consequence of the number of carriages, horses, stores, &c., attached to artillery, and which it is necessary to keep separate, their camp is often enclosed off by picket-posts and ropes, or the carriages are so arranged as to form an enclosure. The position of the parks of the various field batteries attached to an army will of course be fixed by the general rule which holds good for all arms; that each should occupy the same relative position that it would in action, and that its length of front should be the same. This will, however, be modified by the nature of the ground, and by the necessity that exists for artillery having its support close to it, which would render its being placed on the extreme flanks very objectionable. Ordinarily the battery or batteries attached to a division of an army should take up their encamping ground immediately in rear of the intervals between the brigades, so as to be able to move up at a moment's notice; the battery being encamped in line either at full or half intervals. With a large force, the greater portion of the ammunition and stores, with the artillery of reserve, are collected in what is called the grand park, the position of which should be chosen with a view of its being accessible, by the roads in its vicinity, to the whole army.

ARTILLERY TRAIN, a number of guns with their carriages, ammunition, waggons, &c., complete, and fit for marching.

ARTIZANS. In this country it is customary when a young artizan has served his apprenticeship, for him to enter at once as a journeyman; to settle down in some town, usually where he has been apprenticed; and there to work for any master who will employ him. Among the less respectable workmen, or when trade in general is dull, the *tramp* system is acted on; the artizan goes from town to town, a sort of homeless wanderer, seeking work wherever it may be found, and often forced to associate with disreputable companions.

But in Germany the custom is different. There a kind of tramp-system is not merely looked forward to, but is compulsory. The *wanderschaft* of a German workman is a transition period between the life of an apprentice and that of a master. In many parts, both of Germany and of Switzerland, an apprentice cannot obtain his freedom and become a master until he has spent a certain number of years in following his calling beyond his native country. He is furnished on setting out with a book called a *wander-buch*, in which his various employers insert certificates of his service and conduct. In his wanderings he is generally assisted and succoured, not only by the trade to which he belongs, but by the donations of travellers. Many English travellers in Germany have encountered these young workmen, trudging along the roads, with knapsack on back. Mr. Symonds ('Arts and Artizans, at Home and Abroad'), states that, while certain evils arise from this system, it tends on the other hand to give the young men an amount of general information more varied and extensive than is commonly met with among English workmen.

In the Vorarlberg (a part of the Austrian dominions) the male inhabitants are accustomed to leave home early in the spring, go to Switzerland and France, exercise the trades of masons and house-builders during the summer, live with the utmost possible frugality, and return to the Vorarlberg in autumn with the savings of their labour.

The silk-weavers of Lyon have a very strict system of classification. There are small masters, workmen, and apprentices; besides the capitalist-manufacturers who set all to work. The masters or *chefs d'ateliers*, are owners of a few looms, and have fixed residences. The workmen, or *compagnons*, have neither capital, looms, nor houses; they work the looms belonging to the master, live and board with him, and receive half the money gained by the looms they work—the other half going for house-rent, risk, wear and tear of machinery, &c. The *apprentices* are from 15 to 20 years of age; they are taught by the *chefs d'ateliers*, with whom and for whom they work.

ARTOTYRITES. [COMMUNION.]

ARTS, DEGREES IN, such as are now given in our universities, appear to have originated with the incorporation of those bodies in the 11th and 12th centuries. Previous to this period, the distinctions were for the most part of masters and scholars only, as in our grammar-schools of the present day.

The term *master* is believed to be the oldest among those of graduation. Eugenius II. by the 34th canon of a council held at Rome in 826, mentions the appointment of magistri and doctores in the same sentence:—"ut magistri et doctores constituantur, qui studia literarum, liberaliumque artium, ac sancta habentes dogmata assidue doceant" (that masters and doctors be appointed who may continually teach the knowledge of learning and the liberal arts, and the received opinions in religion). This was confirmed by a decree of Leo IV. in another synod at Rome, in 853, (Muratori, 'Antiq. Ital.' tom. iii. col. 830.)

Du Pin, 'Nouvelle Bibliothèque des Auteurs Ecclesiastiques,' 4to. Paris, 1700, tom. x. p. 171, states that the academies or universities which were originally established, were in the 13th century reduced to form. That of Paris, which had begun to be formed in the preceding century, had grown famous from the number of its scholars, and for the masters with which it furnished all Europe. In its origin, he adds, it was composed of *Artists*, who taught the sciences and philosophy; and of Divines, who made commentaries on Peter Lombard's 'Book of Sentences,' and explained the Holy Scriptures. Mention of these two faculties only occurs in the constitutions made for the university by the Cardinal di S. Stefano, legate of Pope Innocent III. in 1215. The whole number of arts was originally *seven*, and these were distributed into the *trivium*, comprehending grammar, logic, rhetoric; and the *quadrivium*, comprehending music, arithmetic, geometry, astronomy. Artidoctor and artista are ancient names for masters of arts, mentioned by Du Cange.

Gregory IX. whose pontificate continued from 1227 to 1241, is said first to have instituted the inferior rank of *bachelors*; whose name was derived from *bacilla* (little staves), either because they were admitted by receiving a little wand, or because as following the title adopted for the novices of the soldiery, who exercised with sticks, in order to learn to fight with arms. The bachelors were exercised in disputations, of which the masters were the moderators. Much upon the etymology of the names of bachelor and master may be seen in Bacmeister's 'Antiquitates Rostochienses,' in the third volume of the 'Monumenta Inedita Rerum Germanicarum,' fol. Lips. 1743, col. 953. The honours conferred upon learned men, in the form of these degrees, greatly increased the number of scholars in all the universities of Europe. For an able sketch of the origin and influence of universities in the middle ages, the reader is referred to the 3rd vol. of Savigny's celebrated work, 'Geschichte des Römischen Rechts in Mittelälter,' c. 21.

From several passages in Wood's 'History and Antiquities of the University of Oxford, there can be little doubt but that the degrees both of bachelor and master of arts were conferred there in the time of Henry III. and the degree of master of arts probably much earlier. The study of law, both canon and civil, and the institution of the Faculty of Law, in which degrees were given, are said to have come into the university in 1149, under the influence and fostering care of Vacarius. (Gutch's edit. of Wood, vol. i. p. 52.)

Wood, quoting the commentaries of one Whetley upon Boëthius, written in the time of Edward I., says, "When the said bachelor was created master, the chancellor gave him the badges with very great solemnity, and admitted him into the fraternity with a kiss on his left cheek, using these words, 'En tibi insignia honoris tui, en librum, en cucullum, en pileum, en denique amoris mei pignus, osculum; in nomine Patris, et Filii, et Spiritûs Sancti.'" (*Ibid.* p. 59.)

The examinations for the degree of B.A. (bachelor of arts) in Oxford have been remodelled by the Examination Statutes of 1850, by which it has been enacted, that all students shall pass three public trials before proceeding to their B.A. degree; these are—

I. Responsions, which are holden three times in each year (that is, 5th of December, Monday after the 4th Sunday in Lent, Thursday after the 1st Sunday after Trinity), and are to be passed in the third to the seventh term inclusive. The subjects of this examination consist of one Latin and one Greek author; Euclid, Books I. and II., or Algebra to Simple Equations inclusive, and Arithmetic as far as the extraction of the square root inclusive, in addition to which a passage of English to be translated into Latin, a paper of Grammatical questions, and a paper of Arithmetical or Mathematical questions are set to all the candidates, who are also examined *vivâ voce*.

II. The First Public Examination under moderators to be passed between the eighth and the twelfth term of standing, taking place twice in the year, and commencing on the 20th of November, and the Wednesday next after the 1st Sunday after Easter; at this examination honours are awarded both in Classics and Mathematics. In order to acquire Classical honours the candidates are desired especially to bring up poets and orators; Homer, Virgil, Demosthenes, and Cicero, being recommended by name. The highest honour cannot be obtained without Logic, which has great weight in the distribution of both honours; Euclid and Algebra however may be substituted for Logic. Philological and critical questions are proposed, as well as Greek and Latin translations in prose and verse. For those who are not candidates for honours (Pass-men), the subjects are Four Gospels in Greek (save in the case of persons not members of the church of England, when some one Greek author is to be substituted), one Greek and one Latin author, of which one must be a poet, the other an orator; in addition to which a piece of English to be translated into Latin, a paper of Grammatical questions, and a paper of Mathematical or Logical questions are set to all the candidates.

III. The Public Examination (held twice in the year, commencing on the Thursday after the 2nd Sunday after Easter, and the 24th of October), at which the candidates must pass in two schools at least (though not necessarily in the same Term), as early as the thirteenth, and for honours as late as the eighteenth term of standing. Prior to the examination the candidates must present a certificate from a Professor, or Public Reader, showing that they have attended two courses of public lectures.

There are four schools, the first of which, that of 'Literæ Humaniores,' has to be passed *first, and by all.*

Candidates for honours may add to the subjects in Divinity prescribed for the pass examination, one or more of the apostolical Epistles and Ecclesiastical History. They have to take up the Greek and Latin languages, Greek and Roman history, Chronology, Geography, Antiquities, Rhetoric, and Poetic, Moral, and Political Philosophy. Logic, which has great weight in the distribution of honours, must be tendered by all who seek to obtain a first or second class. Those who are not candidates for honours are expected to take up the Four Gospels and the Acts of the Apostles in Greek, Sacred History, the Evidences, and the Thirty-nine Articles, with Scripture proofs, unless they are not members of the Church of England, when an equivalent in Greek or Latin, or some one Greek or Latin author is required. One philosopher and one historian, Greek or Latin (no translations into Latin are set).

The second school is that of Mathematics; the minimum for which is the first six books of Euclid, or the first part of algebra: the subjects for honours being mixed as well as pure mathematics.

The third school is that of Natural Science, where the minimum consists of an acquaintance with the principles of two out of these three branches of natural science, Mechanical Philosophy, Chemistry, and Physiology, and with some one branch of science which falls under mechanical philosophy. Candidates for honours are expected to show an acquaintance with the principles of the three branches of natural science named above, and of some one of the physical sciences falling under the above-named branches of natural science.

In the fourth school, that of Law and Modern History, the minimum consists of the History of England from the Conquest to the Accession of Henry VIII., with Blackstone on Real Property; or from the Accession of Henry VIII. to that of Queen Anne, with Blackstone on Personal Property. Justinian's Institutes may be substituted for Blackstone. For honours, the candidates have to present, in addition to the above, in Law, the first and second volumes of Stephen's Commentaries (substituting for these, Justinian's Institutes, and Smith on Contracts); and Wheaton on International Law, or Grotius, Books I. and II.; and Modern History down to 1789. Adam Smith on the Wealth of Nations may also be offered.

After the candidates have been examined, the names of those who have honourably distinguished themselves in the first and second public examinations are distributed, in alphabetical order, into three classes, together with the names of their colleges, under the two divisions of *In Schola Litt. Gr. et Lat.*, and *In Schola Disc. Math.* Those who distinguish themselves in the second public examination are arranged alphabetically in four classes, with the names of their colleges, under these four divisions: *In Literis Humanioribus; In Scientiis Math. et Phys.; In Scientia Naturali; In Jurisprudentia et Hist. Mod.* A fifth class, giving the numbers without the names, is added to each of these divisions. Printed copies of the schedule containing these classes are sent to the chancellor, to the vice-chancellor, to the heads of houses, to the proctors, and to the refectory and common room of each college and hall.

Sixteen terms are required for the degree of bachelor of arts in Oxford from all except the sons, and eldest sons of the eldest sons, of English, Scotch, and Irish peers, and of peeresses in their own right, as well as baronets, and the eldest sons of baronets and knights, when matriculated as such, and not on the foundation of any college; all such persons are allowed to be candidates for the degree after having completed two years' residence. But of these sixteen terms, residence for twelve only is necessary. Of these terms, Michaelmas and Hilary are each kept by six weeks' residence, and Easter and Trinity by three weeks each.

In Cambridge, those who proceed to the degree of B.A. undergo a previous examination (known ordinarily by the name of the *little go*) in the Lent term next after, or next but one after, that in which they have kept their first term, according as such first term be or be not a Lent term: the subjects of which, for those students who are not candidates for honours in the mathematical, classical, and law triposes, are one of the Four Gospels in the original Greek, Paley's 'Evidences of Christianity,' one of the Greek and one of the Latin classics, the Elements of Euclid, Books I., II., & III., and arithmetic; whilst all those students who are candidates for honours in either of the above-mentioned triposes have to pass an examination additional to the one just described in Euclid, Books IV. and VI.; algebra, including quadratic equations, ratio, and proportion; and elementary mechanics.

Between the previous examination and that for the degree of B.A., all students who are not candidates for honours are required to attend the lectures for one term of one out of a certain number of professors specified by grace of the senate Oct. 31, 1848, and to pass a satisfactory examination (conducted by such professor and an assistant examiner) in the subjects of such lectures, at any time between the little go and the degree examination. The mode of proceeding to degrees in arts has been altered by, and in consequence of, the new statutes of the university, which received the royal assent in August, 1858. One most important change has been made by them in the matter of residence, nine terms being the time now required for the degree of B.A.; and, in order to keep any of these terms, a residence of two-thirds of such term is exacted. In consequence of these alterations, changes have been made in the times of examination for the B.A. degree. In the first place, there is no longer an examination for the ordinary degree in the month of January; in the next, there is now in every term an examination for the ordinary B.A. degree on the Thursday before the end of the first two-thirds of each term; and, in the third place, as the great majority of candidates will in all probability present themselves at the examination in the Easter term, at that only are those approved to be arranged in four classes. The subjects of examination for these students are, the Acts of the Apostles, in the original Greek; one of the Greek, and one of the Latin classics; the history of the English reformation; Euclid, books I.—IV. inclusive, and propositions i.-vi. of Book VI.; together with certain parts of algebra, mechanics, and hydrostatics. The examination of those who contend for honours is conducted according to regulations confirmed by a recent grace of the senate, which enacts that questions and problems shall be proposed to the candidates on eight days, the first three being assigned to the more elementary, and the last five to the higher parts of mathematics; that after the first three days an interval of eight days shall elapse, and on the seventh of these days the moderators and examiners shall declare what persons have acquitted themselves so as to deserve honours, who are then to be admitted to the examination in the higher parts of mathematics. After this examination, the moderators and examiners, taking into account the examination of all the eight days, arrange all the candidates who have been declared to deserve mathematical honours into the three classes of wranglers, senior optimes, and junior optimes, which classes are published in the Senate House at nine o'clock on the Friday morning preceding the general B.A. admission. The subjects of the examination on the first three days are, Euclid, Books I.—VI., Book XI., props. i.-xxi., Book XII. props i. ii.; arithmetic and the elementary parts of algebra; the elementary parts of plane trigonometry; the elementary parts of conic sections, treated geometrically; the elementary parts of statics, treated without the differential calculus; the elementary parts of dynamics, treated without the differential calculus; the 1st, 2nd, and 3rd sections of Newton's Principia; the elementary parts of hydrostatics, treated without the differential calculus; the elementary parts of optics; and the elementary parts of astronomy.

By a comparatively recent enactment, it has been declared that the examination of candidates for honours in the classical tripos shall be open to all students who are of proper standing, and that all who obtain honours in the classical tripos shall be entitled to admission to the degree of B.A.

The examinations for the mathematical and classical triposes, and for the ordinary degree of B.A., are conducted entirely by printed papers; at that for the little go, each candidate has to pass a short trifling *viva voce* examination, in addition to that conducted by printed papers.

Bachelors of arts in both universities, though graduates, are considered to be *in statu pupillari*, that is, they are still under nearly the same discipline and control as the under-graduates, except attendance on college lectures. The legislative bodies of the universities consist of those who are masters of arts or who have taken a higher degree.

Masters of arts, in both universities, wear a gown of Prince's stuff, with a semicircular cut at the bottom of the sleeves. The Oxford hood, for a master, is of black silk lined with crimson. At Cambridge, the master wears a silk hood entirely black; the distinction between regents and non-regents is now abolished.

The bachelors of both universities wear black gowns of Prince's stuff; that of Oxford is with a full sleeve, looped up at the elbow, and terminating in a point. At Oxford, the bachelor's hood is edged with fur: at Cambridge, it is lined with lamb's wool.

For further information on the education of Oxford and Cambridge, particularly with reference to the degree of B.A., the fees, &c., see 'Journal of Education,' Nos. i. iii. iv. viii. x. xiii. xv.; on that of Dublin, Nos. xi. xii.; and on the Scottish universities, Nos. vii. viii. ix.; the Oxford, Cambridge, and Dublin 'Calendars;' and also 'Occasional papers on university matters' published at Cambridge by Macmillan & Co.

ARTS, FINE. The Fine Arts are generally understood to comprehend those productions of human genius and skill which, through the medium of the beautiful, more or less address themselves to the sentiment of taste. Art was first employed in embellishing objects of mere utility; but art so employed is now distinguished as Ornamental Art; the office of the Fine Arts is to meet our impressions of beauty or sublimity, however acquired, by imitative or adequate representation. The capacity of the human mind for receiving such impressions, whether directly from nature or through the medium of the arts, depends greatly on civilisation, and that leisure which supposes that first wants are satisfied; but there exists no state of society, however ignorant, in which some symptoms of taste and some attempts to arrest the beautiful are not to be met with. The difference between such efforts and the most refined productions is a difference only in degree. The fact of the existence of the arts in some form may be always taken for granted, and it would only remain to regulate their influence and direct their capabilities aright.

The arts are peculiarly interesting as human creations. They are composed of nature operating on human sympathies, and reflected through a human medium; and as nations, like individuals, present ever-varying modifications, so the free growth of the fine arts partakes of all these varieties, and may be compared to the bloom of a plant, true to its developing causes whatever they may be, and nurtured in the first instance by the soil from which it springs. In barbarous or degenerate nations, the sentiment of the beautiful has ever been attained only in the lowest degree, while a false excitement, founded on the suppression of the feelings of nature, may be said to have usurped the place of the sublime. We smile at the simple attempt of the savage to excite admiration by the gaudiness of his attire; but we should shudder to contemplate the scenes which his fortitude or obduracy can invest with the attributes of sublimity. The just value of life, the characteristic of that civilisation which reduces the defensive passions to their due limits, at the same time naturally elevates the sources of gratification by pointing out the pleasures of the mind as distinguished from those of sense; and the perception of the beautiful is in its turn the cause, as it is in some degree the result, of the rational enjoyment of life.

The great use of the arts is thus to humanise and refine, to purify enjoyment, and, when duly appreciated, to connect the perception of physical beauty with that of moral excellence. But it will at once be seen that this idea of usefulness is in a great measure distinct from the ordinary meaning of the term as applicable to the productions of human ingenuity. A positive use results, indeed, indirectly from the cultivation of the formative arts, precisely in proportion as their highest powers are developed: for it will be found that at all times when the grandest style of design has been practised with success, and particularly when the human figure has been duly studied, the taste thus acquired from the source of the beautiful has gradually influenced all kinds of manufactures. Again, as illustrating science, the fine arts may be directly useful in the stricter sense, but this is not the application which best displays their nature and value. The essence of the fine arts, in short, begins where utility in its narrower acceptation ends. The abstract character of ornament is to be useless. That this principle exists in nature we immediately feel, in calling to mind the merely beautiful appearances of the visible world, and particularly the colours of flowers. In every case in nature, where fitness or utility can be traced, the characteristic quality or *relative* beauty of the object is found to be identified with that fitness;—a union imitated as far as possible in the less decorative parts of architecture, furniture, &c.; but where no utility save that of conveying delight (perhaps the highest of all) exists, we recognise the principle of *absolute* beauty. The fine arts in general may be considered the human reproduction of this principle. The question of their utility therefore resolves itself into the inquiry as to the intention of the beauties of nature. The agreeable facts of the external world have not only the general effect of adding a charm to existence, but they appeal to those susceptibilities which are peculiarly human, and it becomes necessary to separate the instinctive feelings which we possess in common with the rest of the creation, from that undefinable union of sensibility and reflection which constitutes taste, and which, while it enlists the imagination as the auxiliary of beauty, is, in its highest influence, less allied to love than admiration. It is this last feeling which the noblest efforts of the arts aspire to kindle, which not only elevates the beautiful, but reduces ideas of fear and danger to the lofty sentiment of the sublime, which, as its objects become worthier, is the link between matter and mind, and which tends to ennoble sympathy and increase self-respect.

With regard to the classification of the arts, those are generally considered the most worthy in which the mental labour employed and the mental pleasure produced are greatest, and in which the manual labour, or labour of whatever kind, is least apparent. This test would justly place poetry first; but the criterion should not be incautiously applied; for in architecture, where human ingenuity is most apparent, and even where the design is very simple, a powerful impression on the imagination may be excited from magnitude, proportion, or other causes. In such cases, however, it will still be evident that we lose sight of the laborious means in the absorbing impression of the effect, and the art thus regains its dignity. It would be an invidious as well as a very difficult task to assign the precise order in which painting, sculpture, architecture, and music, would follow poetry; but it may be remarked, that the union of the arts is a hazardous experiment, and is often destructive of their effect. This is most observable in the attempts to combine the principles of sculpture and painting. The union of sculpture with architecture may seem an exception, but sculpture so employed becomes subordinate to the sister art and a means of expressing more emphatically the idea of the edifice. The drama itself, which unites poetry with many characteristics of the formative arts, and with music, is in constant danger of violating the first principles of style, viz., the consistency of its conventions; and in the more intimate union of poetry and music, the latter, though the inferior art, is too independent and too attractive to be a mere vehicle, and accordingly usurps the first place. The true principle seems to be that the arts in their higher manifestations must be kept apart; or one must be entirely subordinated and made subsidiary to the other.

All the fine arts it will be seen have something in common. Art is a means of rendering cognisable by the senses an idea or conception which has been formed in the mind of the artist. [ÆSTHETICS.] Art therefore is creative. A true work of art is a representation, not an imitation. Every such work is individual; owes its special value to the thought, or to the mental idiosyncrasy, of the artist, and makes its appeal to the imagination and the judgment—to the emotional and the critical faculties. But whilst there is a consonance in the fundamental idea of all the fine arts, each has its own technical medium, and special conventions, and each therefore has, as we have said, its own distinctive and specific style.

The history and the principles, the specific style and the technics, of the several arts will be found treated of under their respective heads, or the references there given.

ARTS, MANUFACTURING. As the fine arts are destined to the production of objects beautiful rather than useful; so do the manufacturing arts produce results useful rather than beautiful. But in all the later stages of society, these two divisions have tended to coalesce into one: the useful and the beautiful, the *utile et dulce*, being found reciprocally to lend strength to each other. The union of Science with the Arts is becoming, in our own day, more and more apparent.

The establishment of Art-Manufactures, in which sculptors and painters of eminence are employed to design models and patterns for manufacturers; the formation of schools of design, where drawing and modelling with an especial relation to manufactures are taught; the still more recent establishment of artizan schools, where similar instruction is given under different arrangements—all point to a union between fine art and manufacturing art; while mechanics' institutions, lyceums, popular treatises on Science—so far as they have realised the anticipations concerning them—indicate a union between Science and Manufactures. Again, such discoveries as those relating to Photography, Electography, &c., lead to a union between science and fine art. Thus do all three—Science, Art, and Industry—stand in intimate relation one to another.

One of the most remarkable existing collections of specimens in art and manufacture is the Conservatoire des Arts et Métiers, at Paris. This noble institution was the virtual carrying out of a suggestion made by Descartes a century and a half ago—namely, to build a series of large halls, each to contain all the implements necessary to some one trade or department of industry, and to attach to each department a lecturer for the instruction of the people. The institution, which has existed more than sixty years, is supported by a grant of 150,000 francs per annum from the French government. The contents are extensive and well arranged. In one hall or apartment are ancient and mediæval tools, machines, and models; in a second, acoustic instruments of various kinds; in a third, mirrors, and other kinds of optical instruments; in a fourth, porcelain and pottery ware of very choice kinds; in a fifth, articles in Venetian and other glass; in a sixth, chemical and electrical apparatus, old and new. Arranged in other parts of the building are halls and galleries filled with specimens of watch and clock making; drawings and models to illustrate descriptive geometry and the arts of construction; printing types, of every size and nation; models of steam engines and other prime movers of machinery; weights and measures of all ages and nations; weaving and knitting machines; the apparatus used in the manufacture of the *assignats*—the bank notes so famous during the early days of the French revolution; agricultural implements, and models of farm buildings; &c. An ancient chapel has been converted into a lecture and reading room; with the ceiling, walls, floor, and fittings decorated to illustrate ornamental art, and shelves filled with a well-selected library of books in arts and sciences. One of the most interesting halls is filled with objects purchased by the French Government at the Great Exhibition of 1851, in Hyde Park. In most of these halls and galleries, frequent lectures are given to the working men of Paris. Somewhat similar, but at present less complete, is the Museum of the Department of Science and Art at South Kensington.

The exhibition of art-manufactures at Edinburgh in 1857, and portions of the magnificent Art-Treasures Exhibition at Manchester in the same year, were examples of a kind of public display much adopted lately—gradually educating a taste for art among purchasers and producers.

The British Government have annually applied, from the year 1836 to 1859, to parliament, for a grant or grants in furtherance of the cause of education in matters of fine art, manufactures, mining, and science. The systems adopted have been curiously varied, and not always well directed; yet the results have been important—not so much in training up able artists and workmen, as in awakening general attention (partly by public exhibitions, some permanent and some periodical) to the necessity for culture as a forerunner of skill. Some of these government proceedings will be noticed under SCIENCE AND ART, DEPARTMENT OF, and the articles there referred to.

ARUNDEL MARBLES, certain pieces of sculpture, consisting of ancient statues, busts, mutilated figures, altars, inscriptions, &c., the remains of a more extensive collection, formed in the early part of the 17th century by Thomas Howard, Earl of Arundel and Norfolk, and presented, at the suggestion of John Evelyn, in 1667, to the University of Oxford, by Mr. Henry Howard (afterwards Duke of Norfolk), the Earl of Arundel's grandson.

Thomas Howard, Earl of Arundel and Surrey, the founder of this collection, was the only son of Philip, first Earl of Arundel of his family, by Anne, sister and co-heir of Thomas, the last Lord Dacre of Gillesland. He was born in 1586, and in 1603 he was restored in blood by act of parliament, and to such honours as he had lost by his father's attainder, as well as to the earldom of Surrey, and to most of the baronies which had been forfeited by the attainder of his grandfather, Thomas, fourth Duke of Norfolk. The dukedom itself was detained from him. In 1607 he was made a privy-councillor, and in the same year went to Italy, where (with the exception of a brief interval in which he returned to England) he remained till 1614. It was during his residence in Italy that he commenced the formation of his remarkable collection of works of art. After his return to England, he was made, in 1621, Earl Marshal, and subsequently he was created Lord High Steward, in which capacity he presided at the trial of the Earl of Strafford. In 1633 he was sent as ambassador to the Queen of Bohemia and the States General; and in 1636 ambassador extraordinary to the Emperor Ferdinand II. He was created Earl of Norfolk in 1644, and soon afterwards left England. He died at Padua October 4, 1646.

When Lord Arundel determined to collect a gallery of statuary, he retained two men of letters for that purpose. The well-known John Evelyn was sent to Rome, and Mr. (afterwards Sir William) Petty undertook a hazardous journey to the Greek islands and the Morea. In the islands of Paros and Delos, Petty's indefatigable researches had been rewarded with ample success, when, on his voyage to Smyrna, he was shipwrecked on the coast of Asia opposite Samos, and escaped only with his life. At Smyrna he acquired many marbles of great value, particularly the celebrated Parian Chronicle. Still the jealousy of Villiers was active in interrupting Lord Arundel's pursuit, and the delight of his retired hours. Sir Thomas Roe, then ambassador at the Porte, is generally said to have been instrumental (at the suggestion of Villiers) in thwarting Petty's proceedings. But it appears from the correspondence of Roe with the Earl, printed in Appendix B, of Mr. Sainsbury's recently published 'Original Papers Illustrative of the Life of Sir Peter Paul Rubens,' that he really assisted Petty as far as he could do so without incurring the displeasure of the minister. Of Petty, Roe writes to the Earl, "There never was man so fitted to an employment, that encounters all accidents with so unwearied patience; eats with the Greeks on their worst days; lies with fishermen on planks at the best; is all things to all men, that he may obtain his ends, which are your lordship's service." The earl was unquestionably fortunate in procuring the service of such men as Evelyn and Petty, but he also found other zealous assistants in his undertaking. From Mr. Sainsbury we learn that Sir Dudley Carleton, the minister at the Hague,—himself a judge of works of art far superior to most educated Englishmen of his time, and a diligent collector,—was one of the first to contribute to the Earl of Arundel's collection; and that, besides Sir Thomas Roe, "Sir Isaac Wake at Turin, Sir Balthasar Gerbier at Brussels, Sir Francis Cottington and Lord Aston at Madrid, were ambassadors from England, severally written to, and urgently requested to assist him, and give their countenance and support to his several agents in the collection of matters of art" (p. 269).

Lord Arundel having assembled in his gallery his various acquisitions from Greece and the Continent, adopted the following arrangement of his marbles: the statues and busts were placed in the gallery; the inscribed marbles were inserted into the wall of the garden of Arundel House; and the inferior and mutilated statues decorated the garden itself. We learn from catalogues, that the Arundelian collection, when entire, contained 37 statues, 128 busts, and 250 inscribed marbles, exclusive of sarcophagi, altars, and fragments, and the inestimable gems, which included the "very rich collection, as well of medals as other intaglios, belonging to the cabinet he purchased of Daniel Nys (of Venice), at the cost of ten thousand pounds." (Evelyn, 'Diary.')

This was, as his contemporary Peacham notes in his 'Compleat Gentleman,' the first collection of Greek and Roman sculpture formed in this country. It was doubtless the example and influence of the Earl of Arundel which originally induced Charles I. to study and encourage the fine arts, and to form his magnificent collection of paintings.

In 1642, when Lord Arundel left his country, Lord Orford says he transported himself and his collection to Antwerp: Dallaway says (what was no doubt the truth) that his gems, cabinet pictures, and curiosities, only were removed. He adds, "In the general confiscation made by the parliament, the pictures and statues remaining at Arundel House were in some measure included. Many were obtained by Don Alonzo de Cardenas, the Spanish ambassador to Cromwell, and sent into Spain, with the wrecks of the royal collection."

When Lord Arundel died, he divided his personal estate between his eldest and second surviving sons, Henry Frederick Lord Maltravers, and William, afterwards Viscount Stafford. Henry, second son of the former and sixth Duke of Norfolk, succeeded to the elder son's share, and in 1667, influenced by the previous recommendations of Selden as well as Evelyn, gave a part of his moiety (the inscribed marbles) to the University of Oxford; the remainder descended to his son Henry, the seventh duke, and were afterwards mostly possessed by his divorced wife.

Arundel House and gardens were converted into streets about the year 1678, when it was determined to dispose of the statues by sale. It was proposed by the agents to sell the whole collectively, but no purchaser could be found. A division was in consequence made. One portion, consisting principally of busts, was purchased by Lord Pembroke; these are now at Wilton. A second was purchased by Sir William Fermor (the father of the first Earl of Pomfret), who removed them to his seat at Easton Neston in Northamptonshire, where such as were capable of being repaired had their defects amended and supplied by one Guelfi, an artist who misconceived the character and attitude of almost every statue he attempted to make perfect, and ruined the greater number of those which he was permitted to touch. Henrietta Louisa, Countess Dowager of Pomfret, in 1755, transferred these marbles also to the University of Oxford, where they became again united to the inscribed marbles. Mr. Theobald, in a communication to the Society of Antiquaries, made in 1758, says that many of the broken statues, which were thought not worth repairing, were begged by one Boyden Cuper, who had been a servant in the family, and removed by him to decorate a piece of garden-ground which he had taken opposite Somerset Water-gate, in the parish of Lambeth; a place of resort for citizens and others in holiday-time, and long afterwards known by the name of Cuper's Gardens. Here they continued till about the year 1717, when Mr. John Freeman, of Fawley Court, near Henley, in Oxfordshire, and Mr. Edmund Waller, of Beaconsfield, in Buckinghamshire, happening to see them, and observing something masterly in the designs and drapery of several, and that they were fragments of very curious pieces of sculpture, agreed for the purchase of them at the price of 75*l*. One moiety of these went to Beaconsfield, and the other to Fawley Court. A few statues and broken fragments were given to a Mr. Arundel, a relation of the Duke of Norfolk, who rented a waste piece of ground on the opposite shore of the river, which afterwards became a timber-yard; one or two of these were subsequently given to the Earl of Burlington, and went to Chiswick House. A few elegant remains were carried to Mrs. Temple's seat at Moor Park, near Farnham, in Surrey. Various other fragments, which were not thought worth removing, were buried in the rubbish and foundations of the houses in the lower parts of Norfolk Street, and the other buildings on the gardens. Several of these, including a few trunks of statues, dug up at a later time, were sent down to the Duke of Norfolk's seat at Worksop Manor.

The divorced Duchess of Norfolk, by whom the busts and statues were sold, also possessed the cameos and intaglios, and bequeathed them, at her death, to her second husband, Sir John Germaine. His widow, Lady Elizabeth Germaine, who valued them at 10,000*l*., offered them, about 1755, for that price to the curators of the newly-founded British Museum, who were not in a situation to bestow so large a sum upon the purchase; and she finally gave them to her niece, Miss Beauclerk, upon her marriage with Lord Charles Spencer, from whom they passed to his brother the Duke of Marlborough; and are now known by the name of the Marlborough Gems.

Sir William Howard, when afterwards Lord Stafford, succeeded to a house built for his mother, the Countess of Arundel, by Nicholas Stone, in 1638. It stood near Buckingham Gate, and was called Tart Hall. The second share of Lord Arundel's curiosities was deposited there, and, at a sale in 1720, produced 8851*l*. 19*s*. 11¾*d*., and the house was soon after levelled to the ground. This information appears upon the minutes of the Society of Antiquaries.

Dr. Mead bought at this sale Lord Arundel's favourite bronze head of Homer, which is introduced into his portrait by Vandyke; at Dr. Mead's sale it was purchased for 136*l*. by Lord Exeter, who gave it to the British Museum, where it is now considered as a head of Pindar. Lord Orford says, that the coins and medals of the Arundel collection came into the possession of Thomas, Earl of Winchelsea, and in 1696 were sold by his executors to Mr. Thomas Hall.

The greater part of the Greek inscriptions in the Arundel Collection now at Oxford were obtained, as has been already noticed, at Smyrna, where Gassendi says the celebrated Peiresc, who was engaged in similar pursuits, had first discovered them. According to this account, one Samson, Peiresc's factor, had paid fifty crowns for the curiosities, but the Turks having seized on Samson and his collection, with a view to obtain a higher price, the Earl of Arundel commissioned Mr. Petty to redeem the whole. They arrived in England in 1627, soon after which at the suggestion of Sir Robert Cotton, they were carefully examined by the learned Selden, in conjunction with two other eminent scholars. Selden, in 1628, published his 'Marmora Arundelliana,' a thin quarto volume, in which twenty-nine Greek and ten Latin inscriptions of this collection are deciphered and illustrated. The Arundel inscriptions were, at first, let into the wall which surrounds the Sheldonian theatre, each marked with the initial of the name of Howard. They were, however, soon increased by the accession of Selden's private collection, and some other donations; so that the whole amounted to 150 inscribed marbles, including tablets, altars, pedestals, stelæ, and sepulchral monuments. An edition of the whole was now undertaken, at the desire of Dean Fell, by Mr. Humphrey Prideaux, then student of Christchurch, but afterwards dean of Norwich, which appeared under the title of 'Marmora Oxoniensia, ex Arundellianis, Seldenianis, aliisque conflata,' fol. 1676. They were edited with great care, and illustrated by the annotations of the editor, Selden, Lydiat, and others. This work was republished fifty-six years afterwards by Michael Maittaire, under the title of 'Marmorum Arundellianorum, Seldenianorum, aliorumque Academiæ Oxoniensi donatorum; cum variis Commentariis et Indice, Secunda Editio,' fol. Lond. 1732; with great augmentations as to comment. An 'Appendix,' consisting of three Greek inscriptions, subsequently given to the University, was published in 1733, fol. In 1763, the 'Marmora Oxoniensia' were again published in a new and splendid form, under the auspices of the University, by Dr. Richard Chandler of Magdalen College; including the ancient inscriptions collected by Sir George Wheler and Messrs. Dawkins, Bouverie, and Wood, during their travels, some of which Dr. Richard Rawlinson possessed, and a few others; with engravings of statues, busts, and other marbles, to the number of 167 articles, 103 of which belonged to that part of the Arundel Collection which the countess dowager of Pomfret had given to the University. The Greek inscriptions of this collection, 'Ad Chandleri exemplar editæ,' were separately published at Oxford in 1791, in a small octavo volume.

The Arundel and Pomfret marbles are at present preserved at Oxford in two rooms, beneath the Bodleian Library; but it is proposed to remove them to the new Oxford Museum. Of the Arundel portion, that which the University places at the head of its collection is the Greek inscription known by the name of the PARIAN CHRONICLE, so called from the supposition of its having been made in the isle of Paros about B.C. 263. Another inscription of interest is a treaty concluded between Smyrna and Magnesia, for the protection of Seleucus Callinicus, engraved on a pillar in the temple of Venus Stratonicis, at Smyrna, about B.C. 244.

Among the more important marbles of the Pomfret donation are the colossal torso (for that portion only is antique) of a Minerva Galeata, restored as a statue by Guelfi; a Venus Vestita, or Leda; Terpsichore; a young Hercules; an Athleta, which has been called Antinous; a female figure, unrestored, of early Greek work; and three statues of senators, one of which is usually considered as Cicero. This last was etched by Woolridge.

Some of the statues in this collection, which have been restored, as far as the ancient portions go, have no positive attributes of the characters of gods, heroes, &c., which Guelfi, who restored them, made them represent.

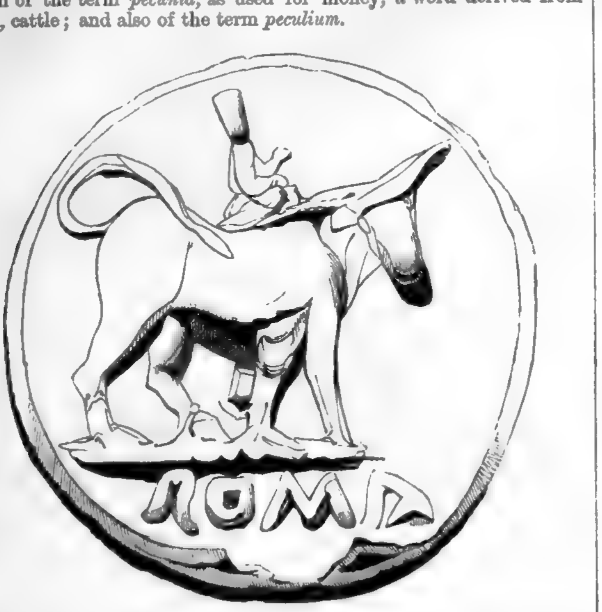
(Dugdale's *Baronage*, tom. ii., p. 277; Lodge's *Portraits of Illustrious Personages*; Selden's *Marmora Arundelliana*, and the *Marmora Oxoniensia* of Prideaux, Maittaire, and Dr. Chandler; Gassendi's *Life of Peiresc*; Gough's *British Topogr.*, vol. ii. p. 127; Lord Orford's *Anecd. of Painting*, edit. 1786, vol. ii. p. 124; Dallaway's *Anecd. of the Arts in England*; Sainsbury's *Original and Unpublished Papers Illustrative of the Life of Rubens*, 8vo, 1859, Appendix B.)

AS, among the ancient Romans, was a weight, consisting of twelve *unciæ* or ounces; it was also called *libra, libella,* and *pondo*, or the pound. Pitiscus ('Lexicon Antiq. Rom.') gives its etymology from the Greek ἄς, used in the Doric dialect for εἷς, signifying an integer or whole, one entire thing; but we can find no authority for this word ἄς. Others, as we learn from Budæus ('De Asse et partibus ejus,' lib. v. 8vo. Lugd. 1551, p. 146), have more correctly considered As to be equivalent to Æs, a piece of copper or brass. (Varro L. L. v. 36, Spengel.)

As, Assis, or *Assarius* (Eckhel, 'Doctrina Num. Vet' tom. v. p. 2) was likewise the name of a Roman coin of copper, or rather of mixed metal, which varied both in weight and composition at different periods of the Commonwealth; but which originally actually weighed a pound, whence it was called *As libralis*, and somtimes also *Æs grave*.

The first coinage of this description, according to Pliny (lib. xviii. c. 3; xxxiii. c. 13), took place in the reign of Servius Tullus, which, if Sir Isaac Newton's chronology of Rome is adopted, would be about the year B.C. 460, or 587 on other authority. The first Ases of Tullus had the figure of a bull, ram, boar, or sow upon them.

Varro ('De Re Rustica,' lib. ii. c. 1), Pliny, and Plutarch ('Poplicola,' edit. Bryan. tom. i. p. 226), assert that the most ancient Ases were so marked. This, in fact, according to the two last writers, was the origin of the term *pecunia*, as used for money, a word derived from *pecus*, cattle; and also of the term *peculium*.



The next in point of antiquity to the As which bore the figure of an animal, is considered by Pinkerton to be the As which was stamped with the two-faced head of Janus on one side, and the prow of a ship on the other. See Pinkerton's 'Essay on Medals,' vol. i. p. 100, who

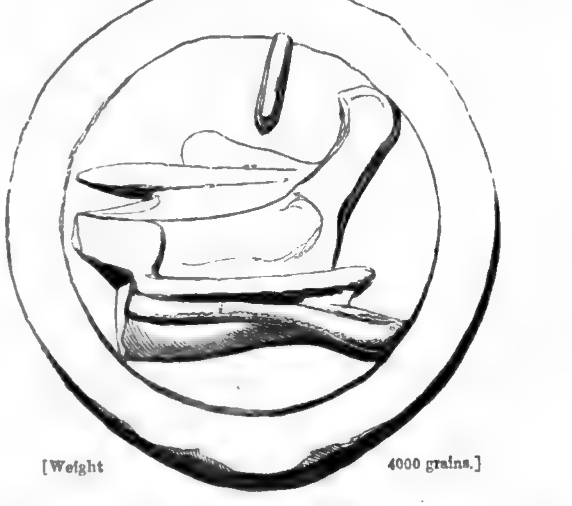
[This As weighs 3872 grains.]

adopts his opinion of this being the second As in point of antiquity, from a manuscript 'Dissertation on the Etruscan and Roman early Coins,' written by Dr. Charles Combe. Ovid, in his 'Fasti,' expressly alludes to the As thus marked; and it is described by Pliny (xxxiii. 3). The head of Janus was usually so accompanied, because, according to an old fable, Saturn arrived in Italy by sea.

> "'Multa quidem didici; sed cur navalis in ære
> Altera signata est, altera forma biceps?
> Noscere me duplici posses in imagine,' dixit,
> Ni vetus ipsa dies extenuasset opus.
> Causa ratis superest: Tuscum rate venit in amnem
> Ante pererrato falcifer orbe Deus."
>
> Ov. *Fasti*, lib. i. 229—234.

The figures on this coin will explain the expression used by the Roman boys in tossing up—*capita aut navim*, 'heads or ship.' (Macrob. 'Sat.' i. 7.)

The earliest Ases were cast, probably in imitation of the Etruscan coins, which the Romans, in this instance, appear to have copied. In the British Museum there are even four Ases united together, as they were taken from the mould or matrix, in which many were cast at once. In most of the Ases preserved in our cabinets, the edge shows evidently where they were severed from each other, and where the



[Weight 4000 grains.]

piece at the mouth of the mould was cut off. From being cast, it will be judged that they are not very correctly sized. As the As fell in weight, the smaller divisions were not cast, but struck.

According to Pliny, the As continued of its original weight till the first Punic war, when, the treasury of the state being exhausted, it was reduced to two ounces. This, however, is improbable, and is confuted by the coins themselves; since we find ases of all weights, from the pound downward to Pliny's two ounces. The As must, therefore, he says, have gradually diminished to ten ounces, to eight, to six, to four; and when the size was so much reduced, still more gradual diminutions must have taken place to three, and to two ounces. One or two of the pieces which remain might even imply that the decrease was more slow, to eleven, to ten, to nine, &c., but it is to be observed that neither the As nor its parts were ever correctly adjusted as to size, so that the marks upon them only, not their comparative magnitude, distinguish the divisions.

The middle of the first Punic war being about the year of Rome 502, or B.C. 250, supposing Pliny to be correct, would be the time of the reduction of the As to two ounces.

Pliny adds, that in the second Punic war, when Q. Fabius was dictator, and the Romans were pressed by Hannibal, the As was further reduced to one ounce. This event is ascribed to the 537th year of Rome, or B.C. 215, being thirty-six years after the former change. He adds, again, that, by the Papirian law, Ases of half an ounce were coined. *Mox* is the word which Pliny uses to indicate the time of this change. A. Papirius Turdus, who was tribune B.C. 178, is suggested by Pighius (ii. 343) as possibly the author of this law; but Eckhel ('Doctr. Num. Vet.' vol. v. p. 5) considers the time uncertain. This weight of the As, however, continued till Pliny's time, and long after.

Pinkerton offers the following sketch of a plan to determine the ages of the different sorts of Ases from their weight:—The As libralis, coined by Tullus, with the figures of oxen, &c., about 167 years after Rome was built, according to Sir Isaac Newton, or B.C. 460; As libralis, with Janus and prow, 400; the As of ten ounces, 300; eight, 290; six, 280; four, 270; three, 260; two, according to Pliny, 250; one, also from Pliny, 214. But this scheme is conjectural, at least down to B.C. 250, and may be considered as intended rather for the amusement of the collector, than as instruction to the sober inquirer.

The As libralis with the head of Janus is the most common form now found of the As, previous to its being reduced to two ounces; a circumstance which shows that form to have been of long duration.

The exact period when the parts of the As were first given, in their proportions of weight and value, is not now ascertainable; but the best authors on numismatic science agree that the time was not very far removed from that of the first coinage of the As.

The coined divisions of the As were the *semis, quincunx, triens, quadrans* or *teruncius, sextans,* and *uncia*. There were other divisions of the As by weight, which it may be proper to enumerate concisely. These were the deunx of eleven ounces, the dextans of ten, the dodrans of nine, the bes of eight, the septunx of seven, the sescuncia of an ounce and a half, and the semuncia of half an ounce. But none of these have been found in a coined form in numismatic cabinets; they are therefore universally considered to have been nominal sums. Indeed it is clear they would not be wanted, for $6+5=11$; $6+4=10$; $6+3=9$: so that these nominal sums were made up of the real coins by adding them.*

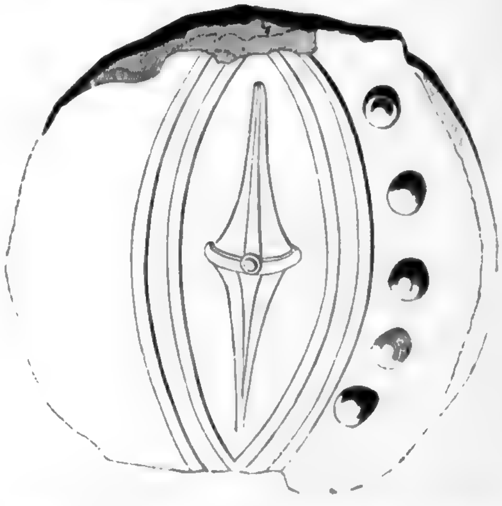
The *Semis, Semissis,* or *Semi-As,* half the As, or six unciæ, was of various types, but always marked with an S. The one here engraved represents a female head on one side, with a strigil behind, or perhaps a hook for reaping or other agricultural purposes, and a head of Pallas on the other: the S, at length, occurs on both sides. Mionnet (' De la Rareté et du Prix des Médailles Romaines,' tom. i. p. 5); and Akerman (' Descr. Cat. of Rare and unedited Roman Coins,' vol. i. pp. 6, 7) have

[Weight 2101 grains.]

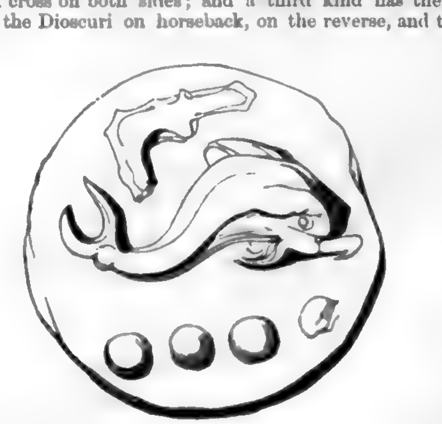
enumerated many different varieties. See also Rasche (' Lexicon Rei Num.' v. Semissis).

The *Quincunx,* the division of five ounces or portions of the As, is of very rare occurrence. All the other portions of the As have been copied for the present work from original coins in the British Museum; but the Quincunx, it is believed, exists in no cabinet at present in this country.

Our present representation of it has been copied from a work entitled ' De Nummis aliquot æreis uncialibus Epistola,' by the Cardinal de Zelada, 4to. Rom. 1778, a volume of extreme rarity, written for the express purpose of illustrating the passages already quoted from Pliny.



The Quincunx here given represents, on one side a bearded head; and, on the other, a buckler, or shield, bearing five globules on the dexter half, which indicate its value. Another type is said to represent a sort of cross on both sides; and a third kind has the head of Apollo, with the Dioscuri on horseback, on the reverse, and the word



ROMA; both these also bear the globules. The last-mentioned type is preserved in the Imperial Cabinet at Vienna.

* Horace (' Ars. Poet.' l. 325) says, the Roman youth learn to divide the As into a hundred parts:

> " Romani pueri longis rationibus Assem
> Discunt in partes centum diducere."

Possibly this passage has a reference to a centesimal division of the As then in use.

It is possible, however, that this which we have engraved may not be a genuine Roman Quincunx; other cities in Italy and Magna

[Weight 1571 grains.]

Græcia had their own Ases, and their divisions, marked in the same manner as those of Rome herself. (Compare Eckhel, *ut supr.* p. 11—13.) These are usually called, in contradistinction, Italian Ases. Such were those of Velitræ, Tudertia, Luceria, Populonia, Panormus, Pæstum, &c.

The *Triens* was the third of the As, or piece of four unciæ. The type here engraved bears a dolphin on one side with the strigil above: on the other is a thunderbolt.

Four globules, or pellets, to indicate its value, occur on both sides. Other types will be found enumerated in Mionnet (*ut supr.* pp. 7, 8); and Akerman (pp. 10, 11). Eckhel says, the head of Pallas was very frequent upon the Trientes ('Doctr. Vet. Num.' tom. v. p. 15). Pliny says (xxxiii. 3) that both the Triens and the Quadrans bore the type of a ship.

The *Quadrans* was the fourth of the As, or piece of three unciæ. The types of this were various also (Rasche, 'Lex. Rei Num.' v. Quadrans); but the value of the coin was uniformly denoted by three globules. On the Quadrans here represented, an open hand and strigil occur on both sides.

[Weight 1108 grains.]

Others have a dolphin, grains of corn, a star, heads of Hercules, Ceres, &c., on the obverse.

The *Sextans* was the sixth of the As, or piece of two ounces. The coin here engraved

[Weight 779 grains.]

bears on one side a caduceus and strigil, on the other a cockle shell. The value is denoted on each side by two globules. On some Sextantes the value is designated on one side only.

The *Uncia*, twelfth of the As, or piece of one ounce, is marked by a single globule. The type we have selected

[Weight 186 grains.]

bears on one side an ear of barley, and on the other a frog. For the varieties of type, compare Mionnet (p. 13); Akerman (p. 17). Eckhel describes one with the head of Pallas on one side, and on the other the prow of a ship: a globule by the side of each.

As the As fell in weight larger denominations of coin were struck, bearing names relative to the As. The As was latterly marked I. The *Dupondius*, or double As, was marked II. The *Tressis* III. The *Quadrussis* IV. There were even *Decusses*, or pieces of ten Ases, in copper, marked X. Olivieri mentions one in his own cabinet weighing upwards of twenty-five Roman ounces, which must have been cast when the As was about three ounces; for, as has been mentioned, they are far from being correctly sized. In the Museum Etruscum is a Decussis of forty Roman ounces, cast when the As was four ounces. The Denarius, Quinarius, and Sestertius were silver coins. According to Pliny, when the As was reduced to one *uncia* in the second Punic war, the *Denarius*, which was originally equivalent to 10, the Quinarius to 5, and the Sestertius to $2\frac{1}{2}$ Ases, were respectively made equivalent to 16, 8, and 4 Ases. On this subject see SESTERTIUS.

Notwithstanding that the As fell, it still continued to be called libra; and in fines of estates, and in other old customs, was, nevertheless, held to be a pound weight of copper. See Cornutus on Persius; that annotator lived in the reign of Domitian. The word *As* was also used in accounts for the whole of any heritage, &c., to late times. *Hæres ex asse* was the phrase used by the jurisconsults for an heir to a whole estate. (Pitisci, 'Lex.' v. As.) It is thus used by Martial (vii. 65), and elsewhere. The word As, indeed, with its subdivisions and multiples, was used generally as the representative of number, both in defining measures of length, the proportions of an inheritance, &c.

The Ases drawn for this article, from specimens in the British Museum, have been carefully weighed. A comparison of the weights will show that the parts do not correspond accurately with one another, or with the integer As. Our specimens may probably not all belong to one epoch, nor all to the city of Rome.

ASAFŒTIDA. A gum-resin obtained from incisions made in the upper part of the root of the *Ferula asafœtida*, which grows in Persia. Asafœtida as met with in commerce consists of agglutinated masses of a brownish colour, possessing an excessively disagreeable odour and taste. Its specific gravity is 1·327. It is very imperfectly soluble in water, but may be dissolved in alcohol rendered either acid or alkaline. According to Brande it consists of

Resin	48·85
Volatile oil	4·60
Gum	19·40
Bassorin	6·40
Acetate of potash / Malate of potash / Extractive matter	1·40
Malate of lime	·40
Sulphate of lime	6·20
Sulphate of potash	trace
Carbonate of lime	3·50
Alumina and oxide of iron	·40
Sand and vegetable fibre	4·60
Water	6·00
	101·75

The *resin* is soluble in alcohol, and yielded analytical results leading to the formula $C_{40}H_{26}O_{10}$, but it is probably a mixture of several substances. The *volatile oil*, to which the characteristic odour of asafœtida is due, is obtained by distillation with water. It is colourless and transparent, very volatile, and possesses a bitter and acrid taste. It is soluble in alcohol and ether, but nearly insoluble in water. Sulphur is one of its constituents.

Asafœtida is used in medicine, and is employed as a condiment amongst some Oriental nations. The green leaves of the plant, and the roasted roots, are also eaten.

ASAFŒTIDA is a gum-resin, obtained from the roots of *Narthex*, or *Ferula asafœtida*, a perennial plant, growing in Persia, in Khorassan, and in the province of Laar. In its recent and purest state it is white and transparent, but by exposure to the air it becomes of a clear brown colour, sometimes verging to red or violet, and of a waxy appearance. At the ordinary temperature of the air it is of the consistence of wax, slightly viscid or glutinous, and becoming soft with the beat of the hand, by which the grains are united into smaller or larger lumps, which, when broken, contain many almond-like pieces. The portions which correspond to this description constitute the best kind of asafœtida, which is called asafœtida in grains.

The inferior sort is dark brown, of a dull, fatty appearance, viscid and greasy, containing portions of the stalks, and other impurities: it is called asafœtida in masses.

Sagapenum, the source of which is unknown, is by many supposed to be a kind of asafœtida.

The smell of asafœtida is penetrating, very disagreeable, and lasts some time. The taste is bitter, unpleasantly aromatic, of an alliaceous or garlic-like character. Its chief component parts are volatile oil, resin, and gum; and it is soluble in vinegar, proof spirit, and yolk of egg. Triturated with water, it forms an emulsion, from which the resin is gradually precipitated. Asafœtida can only be powdered at the temperature of freezing (32° of Fahrenheit); but even after being powdered, though kept in a cool place, it is apt again to run into masses.

An artificial asafœtida is sometimes formed of resin and garlic juice; but this has only a weak smell, and is more perfectly soluble in alcohol.

Asafœtida acts on the human system as a stimulant, more especially of the nerves of the chest and abdomen. It also influences, like all gum-resins, the vessels distributed on the lower portion of the abdomen, or the pelvis. Though not so heating as its chemical composition might lead us to expect, it not only directs the blood more powerfully to these organs, but ensures its uniform supply. It is also a valuable antispasmodic, in irregular action of the muscles either of the respiratory or digestive organs.

Its power of at once rousing the nervous system and promoting the flow of blood towards the enfeebled stomach and bowels, renders it very serviceable in imperfect digestion, attended with constipation.

From a knowledge of its powers in such cases, the Romans employed it along with their food, as the Persians still do.

In hysteria it is extremely useful, both during an attack of spasm, and during the interval between the paroxysms.

In colic, and even ileus, its action is often rapid and effectual, especially if thrown into the rectum: in this way, cases of the most obstinate constipation, especially in hysterical females, have yielded to it.

In asthma, in the later stages of hooping-cough, and in the cough of old age, in cough occurring in weakly subjects, not connected with inflammation or tubercles, above all, in the cough of hysterical females, it is of very great service. In the last-mentioned case, it is improved by combination with myrrh and preparations of iron, as it likewise is when employed to act on the uterine system.

It is also employed externally, as a means of keeping up counter-irritation; and a convenient plaster may be formed by adding 1-12th part of camphor to 11-12ths of asafœtida. For internal exhibition, pills, or tincture, or watery solution (which must be used immediately after it is prepared), are the ordinary forms of administration. In cases of organic disease of the heart, especially enlargement, and in fulness or congestion of the brain or spinal chord, or in any organic diseases of these, asafœtida is improper.

ASARONE ($C_{40}H_{26}O_{10}$)?—*Asarin*, *Asarite*. A volatile principle, obtained from the *Asarum europæum*. It has a remarkable tendency to crystallise in beautifully definite forms. It however readily assumes an amorphous condition, from which it is again easily restored to its crystalline state. The facility which this circumstance affords for the study of crystallisation in general, has been taken advantage of by Schmidt, who has published a paper on the microscopic appearances of this substance during its crystallising condition in the 'Annalen der Chemie und Pharmacie,' for February, 1845.

Asarone is soluble in alcohol and ether, fuses at 104° Fahr., and boils at 536°, but is then partially decomposed.

ASA'RUM, a genus of Plants, belonging to the family of the *Aristolochieæ*. It was formerly employed as an emetic, instead of ipecacuanha; but, from the violence of its effects, it is now properly laid aside in medical practice. It is still however used in veterinary medicine to vomit and purge. [ASARUM, in NAT. HIST. DIV.]

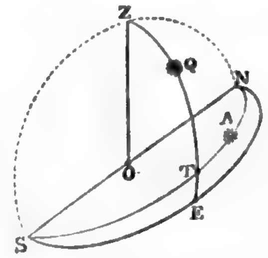
ASBOLINE. [SOOT.]

ASCENDANT. [ASTROLOGY.]

ASCENSION, RIGHT and OBLIQUE, and ASCENSIONAL DIFFERENCE, astronomical terms, of which the two latter are nearly out of use, while the term *right ascension* is preserved, in a somewhat different signification from its original meaning, to denote one of the angles by means of which the position of a star is ascertained.

If we suppose a person at the equator, looking directly towards the east, and raising his arms on each side till they are horizontal, his fingers will then point towards the two poles (which at the equator are in the horizon), and a line drawn through his arms will be a part of the axis on which the heavens appear to turn. Every star will rise vertically; that is, if the diurnal motion were quick enough to justify the phrase, would appear to shoot above the horizon directly upwards. The great circle of the heavens which his eye traces out as he raises his head without turning to right or left, is the equator, and the same point of the equator rises every day with the same star. If there be a remarkable star in the equator, from the rising of which the spectator chooses to begin his *astronomical day*, he will know the time of rising of any star as soon as he knows how far the point of the equator which rises with it is from the star at whose rising he begins to count the twenty-four hours.

Suppose, for example, it is 60°; then, since the whole 360° of the equator rise in twenty-four hours, 60 of them will rise in four hours, or the star will rise at four o'clock of his astronomical day.



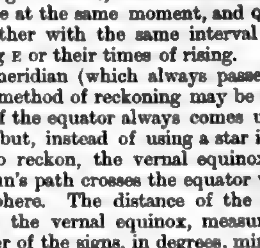
Let O be the spectator, N and S the north and south poles, E the east point of the horizon, E Z part of the equator, and A the star. Through the north and south poles and the star draw a circle N A S, cutting the equator in T. Then, if Q be the star at the rising of which the astronomical day begins, the number of degrees in Q T is the right ascension of the star.

Instead of the horizon N E S, any other circle may be substituted which passes through N and S; for example, the meridian N Z S. For, draw any circle through N and S, then the diurnal motion will bring A and T upon that circle at the same moment, and Q and T will pass that circle one after the other with the same interval as occurred between their times of passing E or their times of rising.

Substituting the meridian (which always passes through the poles) for the horizon, this method of reckoning may be used in any latitude. For the same point of the equator always comes upon every meridian with the same star; but, instead of using a star in the equator as the point from which to reckon, the vernal equinox is preferred, or the point at which the sun's path crosses the equator when he ascends into the northern hemisphere. The distance of the point of the equator just mentioned from the vernal equinox, measured upon the equator according to the order of the signs, in degrees, minutes, and seconds, is the right ascension *in space* [see ANGLE] of the star. The same turned into time [see ANGLE] is the right ascension in *time*, and indicates the interval which elapses between the times when the equinox and star severally come on the meridian. The whole time which a star takes to complete its diurnal revolution, or the *sidereal* day [DAY], it must be recollected, is not the common solar day, but about four minutes shorter.

The old term *oblique ascension* is an extension of the *right ascension*, as derived from our first illustration, to the *oblique* sphere, in which one pole is above the horizon, and the other below.

Let P be the north pole, Z the zenith, E Q the equator, Q the vernal equinox. Let A be a star at its rising, and T the point of the equator which comes to the meridian with it (and would rise with it to a person at the equator). In the latitude represented in the figure, E is the point of the equator which rises with it, and Q E is what used to be called the oblique ascension; the right ascension is Q T, and T E the difference between the oblique and the right ascension, was called the



ascensional difference, but was principally applied to the sun, because when turned into time, it shows the time before or after six o'clock, of sunrise. The ascensional difference is found by the following formula:—

$$\text{Sin. asc. diff.} = \text{tan. latitude} \times \text{tan. star's declination.}$$

When the star's declination is north, *from* the right ascension *take* the ascensional difference; when south, *to* the right ascension *add* the ascensional difference: the result is the oblique ascension.

For the method of determining the right ascensions of the stars, see TRANSIT INSTRUMENT; EQUINOX.

ASCENSION DAY, a festival of the Christian church, on which the ascension of Our Lord is believed by some authors to have been celebrated from the very first century of the Christian era. It has been held for ages on the Thursday next but one preceding Whitsunday. (See Brady's 'Clavis Calendaria,' vol. i. p. 357.) It is also called *Holy Thursday*, a name by which it has been known in this country at least as far back as the time of King Alfred, in whose laws it occurs, On þone halȝan þunreſ dæȝ (or the holy Thursday).

It was on this day, or on one of the three days which immediately preceded it, and which were considered as days of preparation for it, that in ancient times the minister of every parish, accompanied by his churchwardens and parishioners, was accustomed to go round the limits of his district, to deprecate the vengeance of God, to beg a blessing on the fruits of the field, and to preserve the rights and boundaries of the parish. The week in which Ascension Day occurs is usually called Rogation Week, from the Rogations or Litanies which were used in the perambulations. The Anglo-Saxons called the days of this week Ganȝ daȝaſ (walking days), from the perambulations which were made. In London such parochial processions are still observed on Ascension Day itself; and also in some provincial places. In the parish of Lanark, in Scotland, as late as 1845 the 'Statistical Account of Scotland' states that on "Landmark-day, there are processions to inspect the marches of the town-lands. As a method of impressing the boundaries upon the memory, all persons attending for the first time are ducked in the river Mouss." The custom is said to be of Saxon origin.

Pennant, in his 'Tour from Chester to London,' p. 30, tells us that on Ascension Day the old inhabitants of Nantwich piously sang a hymn of thanksgiving for the blessing of the Brine. A very ancient pit, called the Old Brine, was also held in great veneration, and, till within these few years, was annually, on that festival, bedecked with boughs, flowers, and garlands, and was encircled by a jovial band of young people, celebrating the day with song and dance.

It was upon Ascension Day, too, that the Doge or chief magistrate of Venice was formerly accustomed, by throwing a gold ring into its bosom, annually to espouse the Adriatic Sea; using the words 'Desponsamus te, Mare, in signum perpetui dominii." We espouse thee, O Sea, in testimony of our perpetual dominion over thee.—This practice, which is said to have originated in a grant from Pope Alexander III. to the Venetians, of power over the Adriatic Ocean as a man has power over his wife, ceased only with the government of the Doges.

ASCE'TICS (*ἀσκηταί*), a term applied to the pugilists, wrestlers, and other athletæ, among the ancient Greeks, who prepared themselves by abstinence for their combats; subsequently, the term was extended to all those who practised the severity of virtue. The exercise of severe virtue among the Pythagorean and Stoic philosophers was called *ἄσκησις, askesis*: it consisted in chastity, poverty, watchings, fasts, and retirement. The ascetics seem to have had an eastern origin. The Brachmans, Germani or Sarmani, Samanæi, Hylobii or Allobii, Gymnosophistæ in Asia, and other sects in East-Africa, were ascetics, who like the present Sanyasseans, Talapoins, and Bonzes, in eastern Asia, exercised their ingenuity in devising new methods of self-torture. For the Jewish ascetics, see the articles NASIREANS, ESSENES. According to Eusebius ('Hist. Eccles.' ii. c. 23), James the Just, the brother of Jesus, was an ascetic at Jerusalem before the destruction of that city. The Christians were in the earlier centuries more distinguished by their purity of morals than by ascetic austerities. In the 2nd century, the Christians began to distinguish between the commands given to all believers and the evangelical advice which they supposed to be applicable to those only who aimed at the higher sanctity of ascetics, founding their belief more particularly on some passages in St. Paul's epistles, in which he speaks of struggling against the flesh. This double doctrine, as Mosheim calls it, induced many persons to endeavour to attain a higher degree of communion with God, by practising watchings, abstinence, labour, and hunger, hoping thus to raise the soul above all external objects and all sensual pleasures. The Christian ascetics were divided into *abstinentes*, or those who abstained from wine, meat, and agreeable food, and *continentes*, or those who, abstaining from matrimony also, were considered to attain to a higher degree of sanctity. The early ascetics were most numerous in Egypt and Syria. Many laymen as well as ecclesiastics were ascetics in the first centuries of our era, without retiring on that account from the business and bustle of life. Some of them wore the *pallium philosophicum*, or the philosophic mantle, and were therefore called Christian philosophers, and formed thus the transition link to the life of hermits and monks, which was regulated in the 4th century. In modern times asceticism is occasionally used to signify any peculiar austerity of life.

(Mosheim, *De Rebus Christ. ante Const. Max.* p. 311, &c.; Neander's *Kirchen-Geschichte.*)

ASCLEPIADINE. A non-azotised substance of unknown composition met with in the root of the *Asclepias vince toxicum*. It is bitter and emetic.

ASCLEPION ($C_{40}H_{32}O_6$). An inodorous, tasteless, white and neutral substance met with in the juice of the *Asclepias syriaca*. It is insoluble in water and alcohol, but soluble in ether, fuses at 219° Fahr., and at a higher temperature decomposes, emitting an odour like burning caoutchouc.

ASH; ECONOMICAL USES. The uses of the ash in the arts are very numerous. The wood is both elastic and tough; it is used for the felloes and spokes of wheels, the beams of ploughs, the tops of kitchen tables, milk-pails, oars, blocks and pulleys, handles for spades and other instruments, hop-poles, hoops, crates, basket-handles, fence-wattles, and numerous other purposes. In the neighbourhood of the Staffordshire potteries the ash is cultivated to a great extent, and cut every five or six years for crate-wood, which is in much demand in the pottery district. The ashes yield good potash; the bark is used for tanning nets and calf-skins; the leaves and shoots are used for food by cattle; dishonest traders use ash-leaves for adulterating tea; the seeds or *keys* are sometimes pickled as a sort of salad, and they are also used in Siberia to give a flavour to water for drinking. The sap is used for some medicinal purposes. The *Flowering Ash* yields a juice which solidifies into manna.

ASHES, the remains of anything burned, whether of vegetable or animal origin, and to a certain extent of mineral bodies also.

Vegetable ashes. Ashes vary in composition according to the nature of the plant, the soil in which it grows, and the manure used upon it. The substances usually contained in the ashes of land plants are potash, soda, lime, magnesia, silica, the oxides of iron and of manganese, chlorine, carbonic acid, sulphuric acid, and phosphoric acid. Alumina occurs rarely, and sometimes oxide of copper has been met with. Very frequently more than one-half of the ashes of vegetables consists of carbonate of lime. The quantity of ashes varies, not only according to the soil, age, and aspect of the plant, but also in different parts of the same plant, from 2 to 6 per cent. of its weight, after drying in the air. The soluble part of wood ashes consists of the alkaline sulphates, carbonates, and chlorides; while the insoluble matter is chiefly composed of carbonate of lime, and probably of magnesia, phosphate of lime, and phosphate of iron.

The incineration of wood is a most important operation; from its ashes are obtained the immense quantities of impure potash, and the carbonate called *pearlash*, imported from America and other countries. The sap of plants contains also other vegetable acids, as the oxalic, citric, tartaric, malic, &c.; and the salts which these form with potash are decomposed by heat, and yield the carbonate. The ashes of land plants yield principally the salts of potash, such as *barilla*—those of marine plants afford a large quantity of soda salts, and especially the carbonate, such as *kelp*.

Coal ashes are extremely various both in their appearance and composition. Thus, much of the coal of the north of England, under common circumstances, burns to a cinder, which is a mixture of the ashes of the coal with some carbonaceous matter requiring rather a high temperature to burn it, on account of its being enveloped by incombustible matter. The coal of Somersetshire burns to red ashes, evidently coloured by peroxide of iron: those of the Staffordshire coal are nearly white. The quantity of ashes yielded by different kinds of coal varies considerably; according to Kirwan, Wigan coal contains 1·57 per cent, of ashes; Whitehaven coal 1·7, and Swansea coal 3·33 per cent.; they consist principally of silica and alumina, with small quantities of lime, sometimes magnesia, and also peroxide of iron; but they do not contain either the chlorides, phosphates, or alkaline salts found in wood-ashes. *Peat ashes* differ chemically from both the other kinds.

Animal ashes resulting from the burning of bones and other animal solids, consist principally of phosphate of lime, with traces of salts of lime, magnesia, and soda.

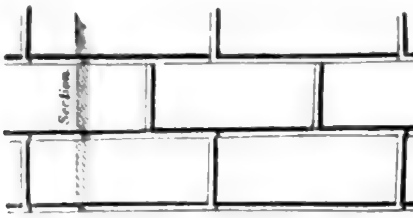
Mineral ashes, such as those of Vesuvius, as examined by Vauquelin, were grayish in colour; they were tasteless, and found to consist of alumina, oxide of iron, muriate of ammonia, sulphate of lime, potash, copper, manganese, lime, and charcoal. Vauquelin also analysed the ashes ejected in the same year from Ætna; they were of a gray colour, and in fine powder; they contained sulphur, sulphates of lime, copper, and alumina, and several other mineral ingredients.

The *ashes* of domestic economy, comprising not only the coal-ash from the grate, but a quantity of dust and miscellaneous fragments, are a valuable commercial article. The ash-heap of a dust contractor has a large money-value, for much of the waste serves as material for manufactures.

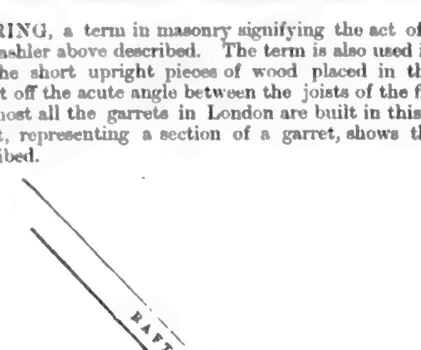
ASHLAR, rough stones of various sizes. This term is applied to free-stones when they are first taken out of the quarry.

ASHLER, a facing made of squared stones. In countries where stone is scarce and expensive, ashler principally consists of thin slabs of stone used to face the brick and rubble walls of buildings. These slabs are generally from four to six inches thick. Ashler is of several kinds. *Plane ashler* is so called when the surface of the stone is made quite smooth. Nearly all the public buildings of London in which stone is used are more or less faced with plane ashler. When the stone shows on its surface a series of narrow parallel flutings, the work is called *tooled ashler*. This is principally to be met with in the basements of buildings where the stone is set with flutings running perpendicularly. There is also an ornamental kind of ashler, very common in buildings, produced by slightly cutting into the stones, so as to make a depression, along one, two, or more of the sides of the joints. This kind of ashler is called *rusticated ashler*. The Banqueting Hall at Whitehall, Somerset House, the Bank of England, and St. Paul's Cathedral, may be taken as examples of rusticated ashler in London:

an example of rusticated ashler on the north side of the western entrance of St. Paul's Cathedral is given in the cut.



ASHLERING, a term in masonry signifying the act of bedding in mortar the ashler above described. The term is also used in carpentry to signify the short upright pieces of wood placed in the roof of a house to cut off the acute angle between the joists of the floor and the rafters: almost all the garrets in London are built in this way. The annexed cut, representing a section of a garret, shows the ashlering above described.



ASHTORETH. [Astarte.]

ASH-WEDNESDAY. This, which is the first day of Lent, had formerly two names; one was *Caput Jejunii*, "the head of the fast," the other was Ash-Wednesday, so called from the ancient ceremony of blessing ashes on that day, with which the priest signed the people on the forehead in the form of a cross, adding this admonition, "Memento, homo, quod cinis es, et in cinerem reverteris:" "Remember, man, that thou art ashes, and shalt return to ashes." "Mannerly to take their ashes devoutly," is among the Roman Catholic customs censured by John Bale in his 'Declaration of Bonner's Articles,' 1554. The ashes used this day in the Church of Rome were said to be made from the palms consecrated on the Palm-Sunday before. In Bishop Bonner's 'Injunctions,' A.D. 1555, we read that "the hallowed ashes given by the priest to the people on Ash-Wednesday are to put the people in remembrance of penance at the beginning of Lent, that their bodies are but earth, dust, and ashes." The ancient discipline of sackcloth and ashes on Ash-Wednesday is at present supplied, in the English established church, by reading publicly on this day the curses denounced against impenitent sinners, when the people are directed to repeat an "Amen" at the end of each malediction. Compare Wheatley 'On the Common Prayer,' 8vo, 1722, p. 227; Brand's 'Popular Antiquities,' vol. i. p. 79. Brady, in his 'Clavis Calendaria,' says, the primitive Christians did not commence their Lent until the Sunday now called the first in Lent. Pope Felix III., in the year 487, first added the four days preceding the old Lent Sunday, to complete the number of fasting days to forty, of which it actually consists. Pope Gregory the Great introduced the sprinkling of ashes on the first of the four additional days, which gave it the name of Ash-Wednesday; and the council of Beneventum, in the year 1091, strictly enjoined the observance of the ceremony, which was abolished in England at the Reformation, and a commination service, as above alluded to, substituted in its stead.

ASIATIC SOCIETIES. The enthusiastic ardour of Sir William Jones in acquiring a knowledge of the languages and literature of the East led him, in 1784, soon after entering upon his judicial functions at Calcutta, to endeavour to interest others in the same pursuit, and thereby to initiate a society in that city on the plan of the Royal Society of London for the purpose, as he intimates in a letter to the Governor-General of India (Warren Hastings), "of inquiring into the history, civil and natural; the antiquities, arts, sciences, and literature of Asia." The Governor-General readily patronised the undertaking; and the society was speedily inaugurated under the presidentship of Sir William himself, who delivered a learned and very interesting discourse on the occasion. To Sir William Jones, therefore, is due the credit of having, in the initiation of the Calcutta Society, set the example which has been followed in the institution of similar bodies in other parts of the world.

The Calcutta Society has been eminently successful. The first volume of its literary labours and scientific proceedings was printed in 1788, in quarto, under the title of 'The Asiatic Researches,' which series was continued up to Vol. XX., published in 1836. In 1832, the society resolved to commence the printing of an octavo journal, or rather to take under its immediate superintendence a scientific journal then existing at Calcutta, under the name of 'Gleanings of Science,' edited by the celebrated James Prinsep. Vol. I. of the 'Journal of the Asiatic Society of Bengal' was issued in 1832; and the work has appeared at regular intervals up to the present time (1859), when it comprises 26 vols., containing, in the aggregate, a vast amount of original information on almost every subject of interest relating to man and nature in Asia. The first 7 vols. are especially rich in the antiquarian, archæological, and numismatical papers of Mr. Prinsep. These papers have been recently collected into 2 vols. 8vo, with notes and elucidations, by E. Thomas, Esq., late of the Bengal C. S., under the title of 'Essays on Indian Antiquities of the late James Prinsep, F.R.S.'

In addition to its own researches and journal, the Bengal Society has been enabled, through the liberality of the late East India Company, to print, under its auspices, various texts of native works, accompanied generally by English translations, under the title of 'Bibliotheca Indica,' the first volume of which appeared in 1836; and the series now comprises about 25 different works, in 4to and 8vo, principally in Arabic and Sanscrit literature.

It was not till about 1820, that the prototype of the Calcutta Asiatic Society was adopted by the orientalists of Europe. At this period a Société Asiatique was formed at Paris, which, in 1822, commenced the publication of the 'Journal Asiatique,' under the editorship of those well-known scholars, Chézy, Klaproth, Remusat, St. Martin, De Sacy, and others of minor fame. The journal has continued to be published with undeviating regularity, and at the end of 1858 comprised no fewer than 70 vols. 8vo, divided into five series. The Société Asiatique has also printed at its own expense some 14 oriental works, besides encouraging by its patronage the printing of several others; and these are sold to the public at prices varying from 1½ to 200 francs per copy.

Nearly simultaneous with the formation of the Paris Society was that of London. In January, 1823, Mr. H. T. Colebrooke, one of the earliest inquirers into the Sanscrit language and literature, convened a meeting of gentlemen at his own house, which resulted in the foundation of the present 'Royal Asiatic Society of Great Britain and Ireland.' The society was well received by the Anglo-Indians of England, and was graciously patronised by William IV., who granted it a royal charter in 1824. The earlier literary labours of the society are recorded in three quarto volumes, dated 1827-35, the contents of which have added greatly to our knowledge of eastern matters. The communications of Mr. Colebrooke and Mr. H. H. Wilson, in these volumes, on the religion, metaphysics, and philosophy of the Hindus, have attracted much attention.

Relinquishing the quarto form of its Transactions, the society commenced the printing of a Journal in octavo, the first of which was issued in 1834. Up to 1858, the Journal had reached its 16th volume. This series contains many learned and valuable papers. Nor must it be forgotten that it was through this society's Journal the antiquarian world was first made acquainted with the remarkable discoveries of Colonel (now Sir Henry) Rawlinson, in the cuneiform writing of ancient Persia, Assyria, and Babylonia. In the year 1838, Colonel Rawlinson sent his first reading of part of the famous Behistun inscription of Darius Hystaspes; and, in 1839, a general précis of the contents of the inscription itself. Several papers on cuneiform literature by Sir Henry have since been printed in the Journal; as also by Dr. Hincks, Mr. Fox Talbot, and Mr. Norris, the present secretary of the institution. Such was the public interest attached to Sir Henry Rawlinson's discoveries, that the House of Commons, in 1856, readily voted a grant of 1000*l.* to the Society in aid of its expenses in printing these interesting memorials of ancient days.

In 1828, a committee originated among the members of the Royal Asiatic Society, who put forth a prospectus for translating and publishing Eastern authors. Colonel Fitzclarence (afterwards Earl of Munster), and Sir Gore Ouseley, took a very active interest in the proceedings of this committee; and considerable funds were collected by annual subscriptions. Since its formation up to the present time, the Oriental Translation Committee has printed or patronised upwards of seventy translations or editions of Oriental books, many of them of high interest,—such as Wilson's 'Vishnu Purana;' De Gayangos's 'Mohammedan Spain;' and the great 'Lexicon' of Haji Khalfa, translated and edited by the learned Arabic scholar, Prof. G. Flügel, of Dresden, in seven thick volumes 4to.

In 1840 another committee emanated from the society, having for its object the publication of oriental texts exclusively. This body have printed the original texts of thirteen authors, in Sanscrit, Arabic, Syriac, and Persian; but from the want of adequate public support, its proceedings are now in abeyance,—as are also, we regret to learn, the proceedings of the translation committee.

It deserves mention, too, that in 1836, the society gave birth to a "committee of commerce and agriculture," the idea of which originated with the Right Hon. Holt Mackenzie and Dr. Royle. After printing a volume of its proceedings, it was dissolved in 1841, when Dr. Royle entered upon his office at the India House for investigating the vegetable products of India—an office which appears to have been suggested by the proceedings of the committee now referred to.

The parent society in London has affiliated as branches the following associations:—1. The Literary Society of Bombay; 2. The Literary Society of Madras; 3. The Asiatic Society of Ceylon; 4. The Asiatic Society of Hong Kong; 5. The Literary and Scientific Society of Shanghai; brief notices of which we shall give *seriatim*.

1. The Bombay Society was instituted in 1804, under the presidentship of Sir James Mackintosh. It has printed 3 vols. of 'Transactions,' in 4to (1819–23); and 5 vols. of 'Journal,' in 8vo (1844–57).

2. The Madras Society owed its origin to Sir John Newbolt. It printed a thin volume of 'Transactions,' in 4to in 1827; since which it has published 19 vols. of its 'Journal,' in 8vo, dated from 1834 to 1838.

3. The Ceylon Society was instituted in 1845, under the patronage of the Governor-General of the island, Sir Colin Campbell. Between 1846 and 1853, it had printed two volumes of its 'Journal;' but we are not aware whether it has published anything since.

4. The China branch at Hong Kong was founded in 1847; and has printed four parts of 'Transactions,' between 1847 and 1855.

5. The Shanghai Society dates from 1858 only; and has printed but one portion of its 'Journal.'

The 'Deutsche Morgenländische Gesellschaft' was instituted in Leipzig, in 1846, under the auspices of Lassen, of Bonn; Rödiger and Pott, of Halle; and Fleischer and Brockhaus, of Leipzig. Its 'Zeitschrift' commenced in 1847, and may be considered a continuation of Ewald and Lassen's 'Zeitschrift für die Kunde des Morgenlandes,' published at Göttingen and Bonn in 1837-50, in 7 vols. 8vo. Its present editor is Dr. H. Brockhaus; and such has been the industry of its contributors that, up to 1858, it comprised twelve dense volumes, with a copious index to the first ten. In addition to the publication of its own proceedings, the society has patronised other oriental works,—such as the 'Indische Studien.' It has also commenced a series of 'Abhandlungen,' &c., one volume of which has appeared.

At Batavia, in Java, a society having similar objects to those already noticed, was founded about 1780; which has published a 'Verhandlingen van het Bataviaasch Genootschap,' &c., which has reached many volumes; and it now prints a 'Tydschrift,' &c. There was also formed a few years since, at Amsterdam, a Royal Institute of Netherlands India, which publishes 'Bijdragen,' &c., besides separate works on subjects connected with the Indian Archipelago.

An oriental society originated at Boston in 1842, and during the next year received from the government an Act of incorporation, under the name of 'The American Oriental Society, for the purpose of the cultivation of learning in the Asiatic, African, and Polynesian languages.' It publishes a 'Journal,' which in 1856 had reached its fifth volume. The library and collections of this society have been recently located in Yale College, New Haven, Conn.

ASPARAGIN ($C_8H_8N_2O_6+2$ aq.).—*Althein, Asparamide.* A substance obtained by concentrating the juice of asparagus until, on cooling, it deposits crystals, which, on recrystallisation from water, are pure asparagin. It is met with also in many other plants, as for instance, in the roots of liquorice, marsh-mallow, and comfrey; in the leaves of belladonna; in the young shoots of hops, in dahlia tubers, &c. Asparagin crystallises in octohedrons or rhombic prisms, which are hard and brittle; they are tolerably soluble in hot water, only slightly so in cold, and insoluble in alcohol and ether. Its solution possesses a slightly acid reaction; but the acid qualities of asparagin are not well pronounced, since it is capable of combining both with acids and bases.

By heating a solution of asparagin in an acid, *aspartic acid* and ammonia are produced.

$$\underbrace{C_8H_8N_2O_6}_{\text{Asparagin.}} + 2HO = \underbrace{C_8H_7NO_8}_{\text{Aspartic acid.}} + \underbrace{NH_3}_{\text{Ammonia.}}.$$

A similar decomposition of asparagin also takes place under the influence of alkalies, and even water heated beyond its boiling point under pressure can produce the same transformation.

Treated with hyponitrous acid, asparagin is converted into malic acid, with separation of nitrogen and water.

$$\underbrace{C_8H_8N_2O_6}_{\text{Asparagin.}} + \underbrace{2NO_3}_{\text{Hyponitrous acid.}} = \underbrace{C_8H_6O_{10}}_{\text{Malic acid.}} + N_4 + 2HO.$$

Asparagin when pure is quite permanent in solution; but impure aqueous solution of asparagin soon begins to ferment, the asparagin disappears and is entirely converted into succinate of ammonia.

$$\underbrace{C_8H_8N_2O_6}_{\text{Asparagin.}} + 2HO + H_2 = \underbrace{C_8H_4O_6,\ 2NH_4O}_{\text{Succinate of ammonia.}}.$$

ASPA'RAGUS, a genus of monocotyledonous plants belonging to the natural order *Asphodeleæ*. It is easily recognised by its very narrow leaves, which drop off the branching stem as soon as they begin to wither, by its small greenish-white or yellowish regularly-formed flowers, and by its seeds being enclosed in a pulpy fruit.

Unlike the principal part of monocotyledonous plants, and especially of those which belong to *Asphodeleæ*, the stems of the different species of asparagus branch like those of dicotyledons, and even become hard and woody; some of them twine and scramble over other shrubs, and certain species even hook themselves to their supporters by means of their stiff and spiny branches, which are stunted and destitute of leaves.

The species are natives of the temperate and tropical regions of the old world, but they are not found wild in either North or South America. The most remarkable one is the common cultivated asparagus which is found in sandy and maritime places in most parts of the middle and south of Europe, the Crimea, and also of Siberia and Japan. It is too well-known a plant to require description, and we shall therefore occupy ourselves exclusively with the method of cultivating it for its succulent and agreeable heads.

An asparagus plant consists of a cluster of fleshy roots connected by the stem, where a quantity of buds are formed, from which branches are yearly emitted. The heads are those branches in a young and tender state; their quality depends wholly upon their size and rapid growth. These are the simplest considerations that are involved in the cultivation of asparagus; the question is how the largest size and the most rapid growth are to be attained.

Seeing what the natural situation of the asparagus plant is when wild, it will be obvious that it should have a light soil which offers little resistance either to the emission of its roots or the protrusion of its stems; the soil should also be capable of both receiving and parting with water readily. Accordingly gardeners take care that all stiff loam, or stones, or solid masses of earth are separated from the soil of their asparagus beds, and that they are completely drained by having trenches 2½ feet deep cut between the beds.

To give vigour to the shoots, manure is added in as great a quantity as the cultivator can afford to apply it; when the seed is sown, or the young plants finally placed in the situation in which they are to produce a crop, an abundant supply of decayed manure, or of bones, or of parings of horses' hoofs, is buried below them; and they are also annually top-dressed with finely pulverised manure, when the beds are arranged in the winter. Attention being paid to these circumstances, asparagus is one of the easiest vegetables of all to cultivate; but no art or skill will produce precisely the soil which is most favourable for its growth. This exists naturally in some places in the fittest of all possible states, and it is there only that it is to be obtained in its greatest perfection; as in the rich alluvial soil of Battersea, Mortlake, and other places round London: in some of these villages it is produced of such extraordinary size that 110 heads in a state fit for the kitchen have been known to weigh more than 32 lbs. There are those who think that this gigantic asparagus is a peculiar variety; but it is ascertained that, on being removed into less favourable soils, it gradually loses its vigour and degenerates into the common kind.

The most convenient breadth for asparagus beds has been found by experience to be 4½ feet, and the least depth for the intermediate trenches 2 feet. The beds are either planted with seedlings one year or two years old, buried six inches beneath the surface, and standing about a foot apart, or sown at once and the seedlings afterwards thinned to such a distance; the latter method is the most simple and the most effectual.

In this country it is frequently forced, but seldom with much success; the heads being usually small and stringy, without sufficient succulence. For this purpose an asparagus bed is dug up, and the plants transferred to a place heated with dung, where they come up in a fortnight or three weeks; but as the roots are always much injured by the operation of transplanting, the little success that attends this method is easily accounted for. In many parts of the north of Europe, especially about Riga, a far better mode is adopted. The forcing takes place in the asparagus beds themselves without disturbing the roots; the trenches are filled with hot dung, and the beds are also covered with the same material about six inches deep; if the weather is very severe, the beds are also covered with frames, but this is rarely necessary in England. Treated thus, asparagus is as fine as if it waited till May to make its appearance. But when this method is practised the heads cannot be cut down at the natural time in the same season. In order to recover from the effect of forcing, they must be allowed to grow as freely as possible during all the succeeding summer, so that they may form a new supply of food for the support of the heads the succeeding spring. Where it is wished to have exceedingly large heads of forced asparagus, pieces of bamboo, or any other hollow tubes, should be put over the shoots when they first make their appearance. The latter will thus acquire a length of as much as eighteen inches without losing their tenderness.

ASPARAMIDE. [ASPARAGIN.]

ASPARTIC ACID. [ASPARAGIN.]

ASPECT, an astronomical term, now entirely disused, applied to the various positions of the planets with respect to one another, as seen from the earth. The terms *conjunction* and *opposition* are the only two out of five names of aspects which have been retained; the remainder being called sextile, quartile, and trine. At *conjunction* two planets have the same longitude; when 60° apart, the aspect is *sextile;* when 90°, *quartile;* when 120°, *trine;* when 180° apart, or opposite, they are in *opposition*. The following are the characters which are used.

Name of Aspect.	Character.	Diff. of Longitude.
Conjunction	☌	0°
Sextile	⚹	60°
Quartile	□	90°
Trine	△	120°
Opposition	☍	180°

ASPERTANNIC ACID. An acid said to be found in sweet-scented woodruff (*Asperula odorata*). Its existence is doubtful.

ASPHALT. A solid bituminous or resinous substance found on the shores of the Dead Sea, in Trinidad, and in other localities. It is doubtless of vegetable origin, and is probably produced by volcanic action upon coal-bearing strata. It is generally black, and more or less lustrous, like pitch, with which, in fact, asphalt possesses much similarity. Oil of turpentine dissolves out of it a black substance, which is insoluble in alcohol and ether, and to which Boussingault has given the name *Asphaltin*; its composition is expressed by the formula $C_{20}H_{16}O_3$.

ASPHALTE. The use of street-pavements formed of asphaltic or bituminous compounds, and especially of that commonly known as the asphalte, or asphaltic mastic of Seyssel, was introduced into this country by Mr. Claridge, under a patent obtained in 1837. The progress which such pavements have made in public favour within the last few years has been less than was at first anticipated. While however comparatively little has been done in the application of asphalte to street-pavements, it has been brought somewhat more extensively into use for foot-pavements in less exposed situations, such as the platforms of railway-stations, for flooring, roofing, and protecting buildings in various ways from injury by damp.

The principal ingredient of the Seyssel asphalte is a dark brown bituminous limestone, found near the Jura Mountains. This stone is broken to powder and mixed with mineral tar and sea-grit; and the whole is exposed for several hours to a strong heat in large cauldrons, until the ingredients, which are continually stirred by machinery, are perfectly united. The mastic is then run into moulds about eighteen inches square and six inches deep, so as to form it into cakes or blocks weighing from 122 lbs. to 130 lbs. each. In this state the asphalte is delivered for use, and portable furnaces and cauldrons are provided for re-melting it upon the spot by fires of wood or coke. In this operation 1 lb. of mineral tar is first put into the cauldron or boiler, to which, as soon as melted, 56 lbs. of mastic, broken into pieces of not more than 1 lb. each, are added, the whole being stirred together. The cauldron is then covered over, and a brisk fire kept up for a quarter of an hour, after which 56 lbs. more of mastic are added and stirred in. The cauldron is again covered for a few minutes, and further quantities of tar and mastic are added, in the proportion of 1 lb. of the former to 112 lbs. of the latter, until the cauldron is full, and the whole is completely melted and fit for use. For some purposes the proportion of the ingredients is different from that above-named.

In laying foot and carriage pavements with asphalte, there is a necessity for securing a firm, solid foundation, which, whenever the ground is soft, must be accomplished by ramming, or by removing the soft earth, and substituting a coarse concrete of gravel and pounded lime-stone.

The modes of applying asphalte to the pavement of cellars and basements for the purpose of excluding damp, vary according to circumstances. Where water is liable to rise under the floor, a brick invert, laid in asphalte as a cement, should be adopted, as the simple pavement laid on concrete will not prove effectual. Damp may be effectually prevented from rising in walls by forming the whole of one horizontal joint a little above the ground level with mastic in lieu of mortar; and skirtings of asphalte, which are formed by pouring the mastic into iron moulds applied to the wall, and assisting its descent with the spatula, may in some cases be applied with advantage. In covering upright surfaces asphalte is not so applicable as in other cases, since it will not bear exposure to the heat of the sun, and will not adhere well to a damp, dirty, or soft surface.

Roofs, especially if of flat pitch, may be advantageously covered with fine asphalte, laid upon a thin coat of fine concrete, supported by a rough boarding of dry wood.

The thickness of asphalte used for pavements varies from half an inch to about an inch and a quarter, the former being sufficient for common floors and court-yards not intended for carriages, and from three-quarters to an inch being the least allowed for carriage pavements; from half an inch to five-eighths is sufficient for roofs and the covering of arches to prevent the filtration of water, and for the lining of tanks and ponds; and about half that thickness is sufficient for covering the ground-line of brick-work, to prevent the rising of damp.

All attempts to employ asphaltic pavements for the foot-ways or carriage-ways of the London streets have failed; the traffic subjects them to a wear and tear greater than they are fitted to bear. Considerable outlay was incurred in the trials made by the various parishes and paving commissioners; so complete has been the failure, however, that at the present time (1859) scarcely an example of asphaltic foot and carriage pavement can be met with in the metropolis.

A useful recent application of asphalte is, as one component of the 'patent asphalted felt,' employed for roofing, sheathing, and other purposes. Its inventors claim for it the properties of impermeability by rain, non-conduction of heat, resistance to vermin, lightness, economy, and durability. Besides roofing and sheathing, it is intended to be applied for lining granaries and stores, clothing or 'jacketing' steam pipes and boilers, and forming a basis or ground for paper-hangings on damp walls. The felt is formed of any refuse fibrous material saturated with melted asphalte.

The so-called asphalte used in the construction of pavement, is chiefly pitch—the residual product of the distillation of coal-tar.

ASPHALTIN. [Asphalt.]

ASPHYXIA, a Greek word (ἀσφυξία) which signifies a cessation of the pulsation, originally expressed any state of disease in which there was a suspension or loss of the heart's action, and a consequent failure of the pulse; but the term is now used to denote a condition of the system in which there is a cessation of muscular movement, an arrest of the circulation, and an accumulation of blood in the veins. The state of asphyxia is that in which the respiratory actions are either temporarily suspended, or have wholly ceased; a state necessarily inducing such a change in the nature of the blood as is incompatible with the continuance of life. The blood which circulates in the two great systems of blood-vessels, veins and arteries, is essentially different [Blood, Nat. Hist. Div.]; that in the veins is incapable of supporting life; that in the arteries is the proper nutrient and excitent of the system. The object of respiration is to convert venous into arterial blood. Of all the conditions necessary to the action of the vital organs, that of receiving a due supply of arterial blood is the most indispensable. If a ligature be placed around the trachea (windpipe) of an animal, so as completely to prevent the access of air to the lung, and if at the same time the carotid artery be opened, that is, one of the great arteries which springs from the arch of the aorta [Heart, Nat. Hist. Div.], and which, passing along the neck to the head, is the main channel through which the brain receives its supply of arterial blood, it is found that in a definite time the blood flowing in this artery has ceased to be arterial, and has become venous. Taking the average of a great number of experiments performed on dogs, for the express purpose of ascertaining this fact, it is found that, in about three-quarters of a minute after the complete exclusion of air from the lung, the blood in the carotid artery begins to lose its vermilion colour. After a minute and a quarter, it has become obviously dark; in the space of a minute and a half, no difference whatever can be perceived between the blood that flows from this artery and ordinary venous blood; in this space of time, therefore, the system of an animal from whose lung air is excluded, is brought completely under the influence of venous blood.

While the blood is thus changing from arterial to venous, the function of the brain is greatly affected. Sensibility diminishes as the blood darkens; and when it has become quite dark, the power of sensation is wholly abolished, and the animal lies in a state of profound coma.

The influence of the circulation of venous blood upon the muscular system is no less powerful than that upon the the nervous, for the muscle can no more perform its function without the stimulus of arterial blood than the brain. When, in consequence of the exclusion of air from the lung, venous blood is sent out to the system, the heart is always the first muscle that feels the effect of this abstraction of its accustomed stimulus; because venous instead of arterial blood is instantly brought into direct contact with the surface of its left cavities [Heart, Nat. Hist. Div.], and because venous instead of arterial blood is sent by its nutrient arteries (the coronary, which are the first branches given off by the aorta) into its very substance; and this blood, as has been already stated, is incapable of affording it the requisite nourishment and excitement. Accordingly the action of the heart is always greatly affected from the very first moment that an animal is brought under this condition. At first, its contractions are somewhat accelerated, probably on account of the violent struggles of the animal, and in consequence of the emotion of fear; but in a few seconds its action begins to be arrested, and it becomes rapidly less and less frequent until it sinks to a point surprisingly low. When in a state of health and unexcited, the pulse of a dog is 130 in a minute; but in two minutes after the exclusion of air from its lung, it sinks to 25, and it often falls still lower. Immediately before death it invariably becomes again accelerated, sometimes rising to its natural standard; but what it then gains in velocity it loses in strength, and in all cases within three minutes after the complete exclusion of air from the lung, the action of the heart has become feeble; this feebleness gradually but rapidly increases, until at the end of the fourth minute it is seldom that the action is at all perceptible by the finger. But though the heart be the first to feel the effect of the abstraction from the system of its usual stimulus, yet the blood which is transmitted to all the other muscles of the body is alike incapable of exciting them to contraction: the muscles of respiration suffer with the rest, so that the respiratory movements, that is, the alternate enlargement and diminution of the cavity of the chest, indispensable to the entrance and exit of fresh currents of air, cease. Not only is the muscular system thus affected, but the capillary system has at last its action suspended, and no more blood passes from the arteries to the veins, and the venous system is greatly congested.

As the circulation fails and the pulse sinks, the muscles termed *sphincter*, that is, muscles placed at the mouths of certain cavities in order to close their passage, that their contents may be retained for a given time, are commonly relaxed; the rectum and the urinary bladder evacuate their contents; often violent convulsions now come on, and immediately before the extinction of life the fæces and urine are expelled with great force.

The phenomena attendant on the state of asphyxia, and which are characteristic of it, are now sufficiently manifest. It is impossible to raise the thorax so as to draw in air, that is, to inspire; nevertheless, violent though vain efforts are made to accomplish this object; but although no air can be introduced into the lung, yet a small portion can be expelled from it, so that the lung is ultimately brought to the extreme state of expiration. Complete exclusion of the air is rapidly followed by the abolition of sensation, this by the diminution and the ultimate cessation of the heart's action, together with the diminution and ultimate cessation of the respiratory movements; and when these changes have terminated in death, the body remains warm for a very long period; the aspect of the countenance is peculiar; the face is swollen; it is either of a reddish violet hue or of a livid colour, and the eyes are clear, bright, and preternaturally prominent. Shakspere's description of this state is physiologically correct:

> "But, see! his face is black and full of blood;
> His eye-balls farther out than when he lived,
> Staring full ghastly, like a strangled man.
> His hair uprear'd; his nostrils stretch'd with struggling;
> His hands abroad display'd, as one that grasp'd
> And tugg'd for life, and was by strength subdued."

As the animal heat is longer retained than is usual in death from other causes, so the coming on of the stiffness consequent on death is longer protracted; but when it has once come on, it is retained for a proportionally longer period.

The morbid appearances in the internal organs observable on dissection are, *in the brain*, turgescence of the blood-vessels, especially of the veins, which are gorged with blood; the blood itself is preternaturally fluid and of an unusually dark colour. No diseased appearance is commonly found in the cavities of the brain, nor is its substance materially changed from the healthy state. *In the respiratory organs*, the mucous or lining membrane of the larynx, trachea, and bronchi are unusually red; the bronchial divisions are of a violet or reddish-brown tint; the lungs are of a blackish-brown colour, and when cut into, large drops of a thick fluid and very black blood ooze out. *In the organs of circulation*, the heart is the organ chiefly affected. Its veins are gorged with dark blood; dark-coloured blood is found both in its right and in its left cavities, but it is invariably accumulated in a larger proportion in its right than in its left cavities; generally there is at least one-third more in the right than in the left. *In the abdominal organs*, the liver, the spleen, and the kidneys are gorged with dark and fluid blood. Thus the blood in all the organs of the system is always unnaturally fluid in consistence and dark in colour.

CAUSES. From what has been stated it is obvious that, whatever is capable of preventing the admission of air to the lungs, or of arresting the chemical action of the air upon the blood, or causing the accumulation of carbonic acid in the blood, is capable of producing the state of asphyxia.

I. Various circumstances are capable of acting in the first mode: 1. Whatever affords a mechanical obstruction to the action of the respiratory muscles, as a heavy weight resting upon the chest. 2. Whatever affords a mechanical obstruction to the due expansion of the lungs, while the respiratory muscles still act with the requisite energy, as the accumulation of fluid in the cavity of the chest, or the diminution of the cavity of the chest by the enlargement or displacement of the abdominal viscera. 3. Whatever affords a mechanical obstruction to the entrance of the air into the lung, as the application of a ligature around the windpipe, causing strangulation; the submersion of the body in water, or drowning; the introduction of foreign bodies into the larynx, trachea, or its divisions, the bronchi; exposure to a too rarefied atmosphere, or to irrespirable gases, such as nitrogen, hydrogen, carburetted hydrogen, carbonic acid gas, &c.

II. The circumstances which are capable of producing the state of asphyxia, by arresting the chemical action of the air upon the blood, are either what may be termed mechanical or vital. The mechanical are those which act in the mode just adverted to, namely, by preventing the entrance of air into the lung, as suspension, submersion, and so on. The vital are those which act chiefly through the medium of the nervous system. If injury be done to the organic nerves which supply the lungs, or if from any cause the nerves of this class fail to supply the lungs with the nervous influence which it is their office to afford, the requisite changes in the blood do not take place. Such an injurious effect upon this class of nerves may be brought about gradually and progressively by the long-continued action of intense cold upon the system, or may be produced instantaneously by a stroke of lightning. The like cause may also act through the nervous system upon the respiratory muscles, stopping the action of what may be termed the mechanical portion of the respiratory apparatus, namely, the alternate enlargement and diminution of the thoracic cavity. Injury done to the other great division of the nervous system, the sentient; injury or division of the eighth pair of nerves; injury or pressure upon the upper portion of the spinal cord (the *medulla oblongata*); injury or pressure upon the spinal cord itself, and especially upon that portion of it which is placed in the neck, whether from fracture or from dislocation of the bones of the spinal column, may destroy the contractility of the respiratory muscles, and thus stop the respiratory movements. It often happens that both sets of causes are combined; the contractility of the muscles of respiration being destroyed by the operation of the same causes which abolish the nervous energy of the lungs.

There are certain varieties of asphyxia which, on account of their practical importance, being states of continual occurrence from accident and otherwise, require a separate consideration. The more important of these are drowning, hanging, strangulation, and suffocation. [RESPIRATION, NAT. HIST. DIV.]

ASPIRATE, or more properly asperate, a name given to one of the divisions of consonants. Grammarians have generally avoided any formal definition of the principle which characterises this or the other classes of letters; they have generally deemed it sufficient to enumerate those letters which belong to each class, and to assign names to these classes without giving any reason for the selection. The subject is confessedly one of difficulty, and it is therefore with much doubt that the following system is proposed.

In the pronunciation of the letters called *tenues*—namely, *k, t, p*,—the moveable organ, whether tongue or lip, comes into the minimum of contact with the organ struck, whether palate, teeth, or lip, and the stroke is rapid. In the pronunciation of the *medials*—*g* (as in *goose*), *d, b*,—the surface of contact is greater, the contact itself closer, and of longer duration. Lastly, in the utterance of the asperated letters, the organs are brought more or less closely together through the whole breadth of the mouth, so that the vibration of air passes through a long narrow fissure. If the pressure or approximation be of slight intensity, and of short duration, the series of asperates, *y, ch* (as at the end of German or Scotch words), *th* as in *thing, ph, w* are produced. If the pressure be closer and more lasting, there result the asperates *gh, th* as in *this*, and *v*. The former series might perhaps deserve to be called asperated *tenues*; the latter, asperated *medials*. The sibilants again seem to have a claim to be admitted under the genus asperate. If this claim be allowed, *s* as in *such, sh* (or *ch* of the French *chemin*), *j* as in the French *jour*, may be called the sibilant *tenues*; and *s* (as in *these*), *ch* (as in the English *church*), *j* (as in the English *journey*), are the corresponding medial sibilants. The letter *h*, which has been omitted in our series, is only a faint *ch* (as pronounced by the Germans). Indeed, if the pedigree of this letter be traced upwards, it will be found to terminate in the Hebrew *cheth*. [ALPHABET.] In the comparison of cognate languages, it is important to bear in mind—first, that the asperated letters are often convertible with one another; and secondly, that they are severally interchangeable with the medials and tenues of the same organ. Thus, 1st, *ch* of the Greek language often corresponds to *h* in the Latin: *cheim* (χειμ-ων, χειμ-ερινος), Gr., *hiem-ps*, Lat., *winter*; *chamai*, Gr., *humi*, Lat., *on-the-ground*; *cha* (χα-σκειν), Gr., *hia-re*, Lat., *to gape*. [GUTTURALS.] 2, *h* in Greek corresponds to *s* in Latin: *hepta*, Gr., *septem*, Lat., *seven*; *hex*, Gr., *sex*, Lat., *six*; *huper*, Gr., *super*, Lat., *above* (*upper*). 3, *th* in ordinary Greek to *ph* or *f* in the Æolic dialect and Latin; *ther*, ord. Gr., *pher*, Æolic Gr., *fera*, Lat., *a wild beast*; *thlib*, ord. Gr., *phlib* in Homer, *press*; *thura*, Gr., *a door*, *fora-s*, Lat., *out-of-doors*; *tharsus* (or *thrasus*), Gr., *fortis*, Lat., *bold*; *thre*, Gr., *fle*, Lat., *bewail*. 4, *th* into *s*, as *sior*, *god*, in the Laconian dialect, instead of *theos*. 5, *th* in ordinary Greek to *ch* in other dialects: *ornith*, ordinary Greek, *ornich*, Doric, *a bird*. Hence in the same language *ith* (ιθ-μα) and *ich* (ιχ-νος) enter into the two forms which signify *a step*; *erch* and *elth* into the two forms of the verb signifying *to go*, ερχομαι, ελθων. Hence too the different forms of the Greek and Latin names for Carthage, *Carchedon*, Gr., *Carthagon*, Lat., in which the second interchange of *d* and *g* compensates for the inverse change of the asperates *ch* and *th*. 6, *f* in Latin corresponds to *h* in Spanish, *faba*, Lat., *haba*, Sp., *a bean*; *fabula-ri*, Lat., *habla-r*, Sp., *to talk*; *fac-ere*, Lat., *hac-er*, Sp., *to do*; *fato* (*fatum*), Lat., *hado*, Sp., *fate*; *formoso* (*formosus*), Lat., *hermoso*, Sp., *beautiful*. For the relation of *sw* and *w* with *h*, see DIGAMMA.

Secondly, the several asperates are, as above stated, interchangeable with the medials and tenues of the same organ. Examples of these changes will readily suggest themselves in every language. The most deserving of attention are perhaps those which exist between the English and German:

initial *k*,	in German,	corresponds to	*ch, sh*	in English.
final *g*	"	"	*w, y*,	"
final *ch*	"	"	silent *gh, ch, k*.	
final *t*	"	"	*th, d*,	"
initial *d*	"	"	*th* in *think*.	
final *d*	"	"	*th* in *the*.	
th	"	"	*d*,	"
initial *z*	"	"	*t*,	"
final *tz, ss*	"	"	*t*,	"
final *b*	"	"	*v, f*,	"
pf	"	"	*p*,	"
final *f*	"	"	*p*,	"
initial *v*	"	"	*f*,	"

(Grimm, 'Deutsche Grammatik;' Becker, 'German Grammar,' English transl. p. 26.)

ASSAMAR ($C_{24}H_{13}O_{13}$). A thick syrup of a reddish yellow colour, and a bitter taste, found amongst the products of the destructive distillation of caramel and sugar. Reichenbach says that toasted bread owes its peculiar bitter taste to this substance.

ASSASSINS, a military and religious order, formed in Persia in the 11th century. It was a ramification of the Ismaelites, who were themselves a branch of the great Mohammedan sect of the Shiites, the supporters of the claims of Ali's posterity to the caliphate. [ALI BEN ABI TALEB, in the BIOG. DIVISION.] But among the Ismaelites there were many who were Mussulmans only in appearance, and whose secret doctrine amounted to this: that no action was either good or bad in itself, and that all religions were the invention of men. These unbelievers were formed into a secret society by one Abdallah, a man of the old Persian race, who had been brought up in the religion of the Magi, and was a hater of the Arabs and of their faith. After several bloody insurrections against the Abbaside caliphs, the Ismaelites succeeded in placing on the throne of Egypt a pretended descendant of Ismael, the seventh Imaum in the line of Ali, from whom the Ismaelites had taken their name. [ISMAELITES.] This descendant, whose name was Obeid Allah Mehdee, was the founder of the Fatimide dynasty, so called from Fatima, Mohammed's daughter. Under the protection of these princes a lodge of the secret doctrine was established at Cairo, and its members spread over a great part of Asia. Their ostensible object was to maintain the claims of the Fatimide caliphs to universal dominion, and to urge the destruction of the caliphs of Bagdad as usurpers. One of the adepts, Hassan ben Sabah, thought of turning these instruments to his own advantage. He was the son of Ali, a rigid Shiite, but living at Rei in Persia, of which the governor was a Soonite, he was forced to conceal his opinions; and further to avoid suspicion, he sent Hassan his son to Nishapoor, to be educated under a celebrated imaum named Mowafek. He here formed an intimacy with Oman Khiam, a poet and astronomer, and with Nizam-al-Moolk, who afterwards became vizir to Alp Arslan, the Seljucide sultan, and his successors. During the reign of Arslan, Hassan lived away from the court; but on the accession of Malek Shah, he applied to his old friend for employment in the government. Nizam-al-Moolk has told his own story, that he introduced Hassan to the sultan, by whom he was highly favoured; but on attempting to supplant his patron he was disgraced and forced to fly. Vowing revenge against the sultan and Al-Moolk, he went to Egypt, where he was received with distinction by the caliph Mostanser, became a zealous adherent of the Ismaelite lodge, and after many vicissitudes and wanderings, obtained possession, by the aid of his brethren, of the hill-fort of Alamoot (or *Vulture's Nest*), situated to the north of Casvin, in Persia, and there (A.D. 1090) established an independent society or order, consisting of seven degrees, with himself at the head as sheikh al jebel, that is, sheikh of the mountain. Under him came three dai al kebir, the grand priors of the order; 3dly, the dais, or initiated masters; 4thly, the refeeks, or companions; 5thly, the fedavees, or devoted; 6thly, the laseeks, aspirants, or novices; 7thly, the prophane, or common people. Hassan drew out for the dais, or initiated, a catechism consisting of seven heads, among which were—implicit obedience to their chief; secrecy; and lastly, the principle of seeking the allegorical, and not the plain sense in the Koran, by which means the text could be distorted into anything the interpreter pleased. This did away effectually with all fixed rules of morality or faith. But this secret knowledge was confined to a few; the rest were bound to a strict observance of the letter of the Koran. The most effectual class in the order were the fedavees—youths often purchased or stolen from their parents when children, and brought up under a particular system of education, calculated to impress upon their minds the omnipotence of the sheikh, and the criminality as well as utter impossibility of evading his orders, which were like the mandates of heaven itself. These fedavees were clothed in white, with red bonnets and girdles, and armed with sharp daggers; but they assumed all sorts of disguises when sent on a mission. Marco Polo gives a curious romantic account of the garden at Alamoot, to which the fedavee, designed for an important mission, was carried in a state of temporary stupor produced by powerful opiates, and where, on awakening, he found everything that could excite and gratify his senses. He was made to believe that this was a foretaste of the paradise of the prophet, reserved for his faithful and devoted servants, and thus became willing to encounter death, even under the most appalling forms, in order to secure a permanent seat in the abode of bliss. Marco Polo's narrative is confirmed by Arabian writers, and Von Hammer inclines to believe it true in the main; others attribute the visions in the garden to the effects of the intoxicating preparation administered to the fedavees. The name of *hashish*, which is that of an opiate made from hemp-leaves, is supposed to have been the origin of the word 'Assassins;' others derive the latter from Hassan ben Sabah, the founder of the order. The word becoming familiar to the crusaders, was by them carried to Europe, where it was used as synonymous with that of *sicarius*, or hired murderer; but the Italians have adopted it to signify a robber on the high road, without necessarily implying the crime of murder.

The Assassins, either by force or treachery, gained possession of many other castles and hill-forts in Persia. The sultan Melak Shah attacked them, the doctors of the law excommunicated them; but the fedavees carried secret death among their enemies; the sultan's minister, Nizam-al-Moolk, was stabbed, and his master soon after died suddenly, it was supposed by poison. The Assassins spread into Syria, where they acquired strongholds in the mountains near Tripoli; and the sultan of the Seljucides was glad to come to an agreement by granting them several districts. Hassan ben Sabah, having extended his order over great part of the Mohammedan world, died at Alamoot in 1124, after thirty-five years' reign. He bequeathed his authority to Keah Buzoorg Oomeid, one of the dais of the order. Buzoorg renewed the war with the Seljucides, and Aboo-'l-Wefa, his dai al kebir in Syria, entered into a temporary alliance with Baldwin II., king of Jerusalem, through the agency of Hugo de Payens, grand master of the Templars, against their common enemies the Seljucide Turks. After this, the Assassins were sometimes on friendly terms, but oftener at variance, with the Christian princes of Syria and Palestine, as well as with their Mohammedan neighbours. To accomplish their object they never scrupled to resort to assassination. In 1126 the prince of Mosul was stabbed as he entered the mosque by Assassins disguised as dervises; soon after, a caliph of Bagdad was killed likewise, and also a sultan of Cairo, notwithstanding his Fatimide descent. In 1138 Keah Mohammed succeeded his father. In 1151 Raymond, count of Tripoli, was stabbed by the Assassins; it was suspected, at the instigation of his wife. At this time the Syrian branch of the Assassins had acquired a large extension of power, and became in a manner independent of the Persian one. A son of Mohammed's, Hassan, proclaimed himself to be the promised Imaum, and gained numerous followers; but his father cast him into prison, and put 250 of his adherents to death. Hassan then renounced his pretensions, but on succeeding his father in 1163, he assembled all the people in Alamoot, proclaimed that they were the true elect, and absolved them from all the obligations of the law of Islam. After a succession of enormities that seem almost like madness, he was assassinated by his brother-in-law. His son, however, succeeded him as Mohammed II., and took a bloody revenge for his father's murder. After a reign of thirty-five years, Mohammed was succeeded by his son Jelial-ed-deen, in 1173. Jellal-ed-deen was a man of more sense than his predecessors; he restored the religion, made his peace with the caliph, sent his harem on the great pilgrimage to Mekka, and received the appellation of New Mussulman. After a short but peaceful reign, he was poisoned by some of his kindred, and was succeeded by his son Ala-ed-deen when only nine years of age, who being murdered, the office of sheikh al jebel devolved upon Rukn-ed-deen, Ala-ed-deen's son. By this time the caliph of Bagdad had applied to the great Mongol conqueror, Mangoo Khan, who sent his brother Hulakoo to exterminate the murderous sect. Alamoot was taken, and Rukn-ed-deen was made prisoner and ultimately put to death. The fortress Kirdcoo resisted for three years, but at last all the haunts of the Assassins were taken, and the inmates were massacred without distinction, A.D. 1256.

The Syrian or western branch of the Assassins, however, continued to exist for some years later under their dai al kebir. Massyad, not far from Beyroot, was their principal stronghold. The history of this branch is the most familiar to Europeans, being much interwoven with that of the crusaders and of the great sultan Sala-ed-deen. The latter was several times in danger from the daggers of the Assassins. The Dai al Kebir Sinan, a man who had a reputation for sanctity, sent in 1173 an embassy to Almeric, the Christian king of Jerusalem, offering, in his name and that of his people, to embrace Christianity, on condition that the Templars, who were their neighbours, should remit the annual tribute of two thousand gold ducats which they had imposed on them, and live in future in peace and good neighbourhood towards them. Almeric was delighted with the offer, and dismissed the envoy with honour. The envoy, however, on his return to his territory, was killed by a party of Templars, led by Gaultier du Mesnil. After this the Assassins resorted again to their daggers, which they had laid aside for many years. Among other victims, Conrad, marquis of Tyre and Montferrat, was murdered by two fedavees in the market-place of Tyre, 1192. The reasons for this murder, which some have ascribed to Richard of England, have been the subject of a long controversy, which Von Hammer does not succeed in elucidating. The Assassins kept the Christians of Tripoli in perpetual fear. They levied contributions on the Christian princes for the safety of their lives; and they even demanded it of St. Louis, King of France, on his passing through Acre on his return from the Damietta expedition: Louis, however, indignantly refused. At last the Syrian Assassins were conquered, and their stronghold taken, by Beibars, the Mamluke sultan of Egypt, fourteen years after the destruction of the eastern branch by the Mongols. Many, however, found refuge in the mountains of Syria, or became mixed with the Yezeed Koords; and some of the tenets of the order are believed to linger still among them. The Syrian Ismaelites are divided into two sects, who live in a number of small villages round Massyad. The Persian Ismaelites dwell chiefly around Roodbar, in Khorasan, their sheikh living under the protection of the Shah of Persia.

(Von Hammer, '*Geschichte der Assassinen*,' and '*Fundgruben des Orients*;' also Sir John Malcolm's '*History of Persia*.')

ASSAULT and BATTERY. An assault has been commonly defined to be 'an attempt or offer with force and violence to do a corporal hurt to another.' Thus, presenting a gun at a person within the distance to which it will carry, throwing a stone or other missile at him, drawing a sword and waving it, or even holding up a cane or a fist in a threatening manner, are given as instances of assault. An assault does not necessarily imply any corporal injury done to the party assaulted; pointing or snapping a loaded gun at a person behind his back, so that he is not aware of his danger, would be an assault, though no actual injury is sustained. But it has long been settled law, that no words, however insolent and provoking, unaccompanied by an act of violence, can amount to an assault.

A *battery*, which is said to imply an assault, consists of any kind of corporal injury, however small, designedly done to another by an actual contact with his person. Thus, throwing water on another is a battery. The injury need not be done by the immediate hand of the party; nor is it material whether the act is wilful or not, provided it proceeds from a mischievous design. Thus, where a lighted squib was thrown into a market-place, which was tossed about from hand to hand and at last struck a man in the face and put out his eye, it was held to be an assault and battery by the first thrower.

A person who commits an assault or battery is liable to an action by the party injured, and also to a criminal prosecution for a misdemeanor and breach of the peace; but the proceeding by indictment and action for the same assault is always discouraged in practice; and where a defendant is found guilty upon an indictment, and the court is informed that an action has been brought for the same injury, a nominal sentence is usually passed, unless the prosecutor will consent to discontinue his action.

It is not uncommon to permit the prosecutor of an indictment for a common assault to compound the offence with the defendant even after he has been convicted; and upon the declaration of the former that he is satisfied, a nominal punishment only is imposed. This practice, which is called *speaking with the prosecutor*, has been introduced for the purpose of reimbursing the person really injured the expenses of the prosecution, and of compelling the offender to make him some compensation, without the circuity of a civil action. Though sanctioned by long usage, it is a relaxation of the strict rules of the criminal law, and is liable to much objection in principle, as enabling an individual to assume the character of a public prosecutor for the purpose of redressing a private wrong. This objection to the practice has been strongly animadverted upon by Sir William Blackstone, and it is now much less frequent than formerly. ('Commentaries,' Mr. Kerr's ed. vol. iv. p. 430.)

The punishment of persons convicted of common assaults is fine and imprisonment at the discretion of the court, exercised upon the circumstances of each particular case. By a variety of statutes, assaults aggravated with respect to the place where, or the persons on whom, they were committed, were formerly punishable with great severity. ('Blackst. Comm.,' vol. iv. chap. 15.) Most of these statutes were, however, repealed by stat. 9 Geo. IV. c. 31, which authorised an increased punishment upon certain specified cases of aggravated assaults. This last statute has, however, been in its turn repealed, and the enormity of offences against the person made to depend in a great measure on the intent of the offender; see 7 Will. IV., and 1 Vict. c. 85. Some offences not contemplated by this statute are provided for by statutes 9 & 10 Vict. c. 25; 14 & 15 Vict. c. 19; and 16 & 17 Vict. c. 30. Other statutes apply to particular cases, as assaults on officers of a workhouse, on apprentices, &c. See 'Blackst. Comm.' Mr. Kerr's ed. vol. iv. c. 15.

The statute of 33 Henry VIII. c. 12, which punishes assaults in the king's palaces with the loss of the right hand and perpetual imprisonment, was repealed by the 9 Geo. IV. c. 31; but it seems that the penalty of the loss of the right hand attached by the common law to assaults committed in the actual presence of the king, or in his constructive presence in the superior courts of law, still remains. This subject was much discussed in a case which occurred in 1799, when the Earl of Thanet, and several other persons, were convicted of a riotous assault and rescue in a court of Oyer and Terminer and Gaol Delivery at Maidstone. Upon their being brought up for judgment, the court of King's Bench entertained doubts whether it was not imperative upon them to pass the specific sentence of amputation; but the attorney-general entered a *Noli prosequi* as to those parts of the charge upon which the doubts had arisen. (Howell's 'State Trials,' vol. xxvii., p. 822.)

Actions for trivial assaults were formerly among the most frequent subjects of litigation in our courts of justice. An attempt was made to discourage them by 22 & 23 Car. II. c. 9, which has to some extent been re-enacted by stat. 3 & 4 Vict. c. 24, providing that the plaintiff, in case the jury shall find the damages to be under 40*s*., shall recover no costs unless the judge certify that the grievance was wilful and malicious.

Persons guilty of common assaults may be convicted summarily by two magistrates, who are empowered to impose a fine not exceeding 5*l*., with the costs; and in case of non-payment, to commit offenders to prison for two months. A certificate that the complaint was dismissed as trivial, or that the assault complained of was justified, or payment of the fine adjudged, or completion of the term of imprisonment for non-payment thereof, is a bar to all further proceedings, criminal or civil, for the same cause.

ASSAULT is in Scotland an offence usually prosecuted by the public prosecutors attached to the sheriffs' courts, to the police courts established by statute, and to the justice of peace courts, and punishable by imprisonment. It is seldom brought before the supreme criminal court, that is, the high court or the circuit courts (or lords commissioners) of justiciary, unless it be of a highly criminal character; and it is then generally charged as assault with some specific aggravation, as "assault aggravated by being to the effusion of blood," or as "being to the danger of life," or "by being committed against a magistrate," or "by being perpetrated with a lethal weapon," an expression applicable to a sword, hatchet, hammer, or any instrument more formidable than an ordinary walking-stick. The punishment in such cases is more severe, being generally a lengthened imprisonment or penal servitude. Criminal prosecutions for assault, at the instance of private parties, are almost unknown. The party injured may sue for damages, but such actions are not frequent. There is no division, as in England, into 'assault,' and 'assault and battery.' Many of the statutes as to specific assaults, for instance, assaults in pursuance of a combination to raise wages, extend to Scotland.

ASSAYING, a chemical operation, which differs from analysis only in degree. When an analysis is performed, the nature and proportions of all the ingredients of a substance are determined; but in assaying, usually, the quantity of any particular metal only which the ore or mixture under examination may contain is ascertained, without reference to the substances with which it is mixed or alloyed.

The operations of assaying are sometimes conducted entirely in what is called the *dry way*, or by heat; at other times in the *moist way*, or by acids and other reagents; and in some cases both methods are necessarily resorted to in assaying the same ore or mixture of metals.

The use of the term assaying is sometimes restricted to alloys or mixtures of gold and silver; but in the present article we shall point out the methods of assaying the ores of the following metals also—copper, iron, lead, tin, and zinc.

The assaying of silver and gold is effected by a process called *cupellation*. Cupels are small flat crucibles, made by pressing bone ash, moistened with water, into circular steel moulds, and they are dried by exposure to the air. The principle upon which the operation depends is, that all metals with which gold and silver are usually alloyed are convertible into oxides by exposure to atmospheric air at a high temperature, whereas the precious metals remain unacted upon. The oxides are miscible with fused oxide of lead, and are absorbed with the latter into the pores of the cupel.

Silver.—To assay silver by cupellation, it is requisite to obtain lead as free as possible from silver; when it is procured by reducing litharge, it contains only about half a grain of silver in a pound; and this portion may be neglected. The silver to be assayed is flattened and made quite clean; about thirty-six grains are to be weighed and wrapped up in the proper quantity of lead, which depends upon that of the base metal in the alloy; this, if coarse, is harder than standard silver, of a brilliant glassy appearance, and is flattened with difficulty on the anvil; if soft, easily flattened, and of a dead-white colour, a nearer approach to purity is indicated. The quantity of lead must then be apportioned according to the experience of the assayer, and varies from three to fifteen times the weight of alloy to be operated on. It is to be observed, that cupels do not absorb more than their own weight of oxide of lead, and also that, if the quantity of this metal be too large, some of the silver is carried with the oxide into the cupel, and a loss of product is incurred.

The alloy and lead are to be put into a cupel when made very hot in a small earthen oven, called a *muffle*, which is placed in the assay furnace; the mixture soon fuses, is covered with a coat of oxide of lead, becomes flattened, gives off fumes, and considerable motion ensues on its surface. The lead thus gradually oxidises, and the oxide fusing is absorbed by the cupel, and carries with it the baser metals, also oxidised, with which the silver was alloyed. The alloy is at first flat, but becomes gradually convex, and presents continually increasing shining points; when this happens, the cupel is to be brought forward to the mouth of the muffle; the shining points disappear, the silver becomes brilliant, and the operation is complete. Care must be taken to allow the assay to cool very gradually. Its weight will denote the amount of fine silver contained in the quantity of alloy subjected to examination.

The assay of silver by the *humid* or moist way is now more generally adopted than the process of cupellation. Dr. Miller, in his 'Elements of Chemistry,' says, "The results of the process of the assay by cupellation, even in experienced hands, may vary as much as two parts in 1000; this circumstance induced Gay Lussac to contrive a different method, which is now adopted, not only in the French mint, but is employed in the mints of Great Britain and the United States, as well as in almost all the mints of Europe; it admits of an accurate estimate of the value of an alloy to within 0·5 in 1000. This process depends upon the precipitation of the silver in the form of an insoluble chloride, and the measurement of the amount of a standard solution of chloride of sodium which is required to effect the complete precipitation of the silver in a given weight of the alloy. Chloride of silver easily collects into dense flocculi by agitation in a solution which is acidulated with nitric acid, and which contains no excess of soluble chlorides; so that the exact point at which the precipitate ceases to be formed is readily perceived.

"A solution of common salt is prepared of such a strength, that 1000 grains of it are exactly sufficient to precipitate ten grains of pure silver. Ten grains of the alloy for examination are placed in a stoppered bottle, capable of holding about six ounces of water, and by the aid of a gentle heat are dissolved in two drachms of nitric acid, of specific gravity, 1·25; the solution of salt is then placed in a burette (*fig. a*) capable of holding rather more than 1000 grains. The burette, when filled with the solution, is weighed before being used, and the liquid is added to the nitrate of silver in the bottle; when it is supposed that the silver is nearly all precipitated, the liquor is briskly agitated in the bottle, and the precipitate is allowed to subside; a drop or two more of the solution of salt is then added; if a precipitate be produced, the liquid is again agitated, and when clear more of the solution is added, as before, as long as any turbidity is produced by the addition. When a cloud ceases to be formed, the proportion of solution of salt which has been added is ascertained, by weighing the burette a second time. The number of grains of the solution employed indicates the degree of fineness of the alloy."

Fig. a.

Gold.—The assaying of gold is performed, to a certain extent, exactly in the same way as that of silver by the dry way; and if the gold were alloyed only with copper, the process would be as simple as that of silver assaying. Usually, however, gold contains silver, and this cannot be got rid of by cupellation; the *parting* process is therefore had recourse to. This consists in dissolving the silver by dilute nitric acid, which leaves the gold perfectly pure, unless the silver is so small in quantity as to be protected by the gold from the action of the acid, which is very commonly the case. To obviate this difficulty, the gold alloy, supposing it to weigh twelve grains, is to have thirty-six grains of pure silver added to it (hence the name *quartation* given to this process), and to be cupelled with one hundred and eight grains of lead. The button obtained is to be flattened into a plate of about one inch and a half long, and four or five lines broad, returned to the furnace, kept for some time at a red heat, taken out and suffered to cool, and rolled up about the size of a quill. This is to be put in a matrass with about three times its weight of nitric acid, of sp. gr. 1·25, and heated on a sand-bath. By the action of the acid the silver is dissolved, and the *cornets*, as they are termed, of gold, are left of a dull-brown colour, and without any metallic appearance; these are repeatedly washed with distilled water, and heated in small clay crucibles to bright redness. The pieces of gold having thus acquired their usual appearance and properties, are to be weighed, the absolute loss in weight indicating the purity of the alloy subjected to trial.

Iron ores are chiefly of three kinds: the impure protocarbonate, commonly called the argillaceous iron ore; the peroxide, including the specular and hæmatite iron ores; the black or magnetic ore, which is a compound of the protoxide and peroxide. The argillaceous iron ore is that which supplies by far the greatest proportion obtained in Britain; the hæmatite occurs in North Lancashire and many other places; the mines of Elba yield the specular ore; whilst the Swedish iron is obtained principally from the magnetic ore.

Various methods have been proposed for assaying these ores, but the principle is in all of them the same; it is that of separating the oxygen from the iron, by the greater affinity of charcoal for that element at high temperatures. The operation of the charcoal is frequently assisted by the use of a flux to combine with the earthy matter, and to convert it into such a glass as will let the melted metal easily fall through, and form, on cooling, a clean button. A flux composed of lime and bottle glass has been used, or the clay which accompanies the argillaceous iron ore is to be burnt and mixed with an equal weight of lime; 200 grains of the powdered ore may be mixed with an equal weight of this flux and forty grains of powdered charcoal; the mixture, put into a Cornish or Hessian crucible, is to be heated in a wind-furnace or a forge. It is not always easy to apportion the charcoal exactly to the oxide of iron in the ore; when it is either too large or too small, the product of iron is deficient, and this will be denoted by the imperfection of the glass.

In the Supplement to the 'Encyclopædia Britannica,' Mr. Mushet has given the results of using various fluxes with an iron ore that yielded forty-six per cent. of the metal; and it appears that the following mixture of the ore and substances, all of course reduced to powder, gave the largest proportion of iron: ore, 200 grains, lime 100, borax 100, charcoal 40, gave 91 of metal; it is therefore evident that only one-half per cent. of iron remained in the glass.

According to M. Descotils ('Ann. de Chimie,' t. 84, p. 188), the earthy portion of the argillaceous iron ore is frequently such as to form a glass without adding any flux whatever to the charcoal. He used crucibles lined with a mixture of clay and charcoal; and thus, among many other assays, with nearly similar results, an ore which was found by analysis to contain about 37¾ per cent. of iron yielded 36 per cent. of the metal, and the glass was of excellent quality.

Copper ores, with reference to the mode of assaying them, may be divided into two classes—those that contain sulphur, and those that do not. The former class may be subdivided into such as also contain iron pyrites, arsenic, tin, lead, zinc, &c., with a considerable quantity of earthy matter; and such as are composed principally of a mixture of the sulphurets of copper and iron, with but small portions, if any, of other metallic or earthy minerals.

To treat the first subdivision of the sulphureous ores (which constitute a large proportion of all copper ores sold in Great Britain), a flux should be prepared by mixing the following ingredients in the under-mentioned weights:—

2 parts	Fluor spar,
1 ditto	Slaked lime,
1 ditto	Borax,
1 ditto	Red argol (impure tartar),
½ ditto	Nitre,

all finely powdered and well mixed.

The sample of ore being reduced to a coarse powder, take 400* grains of it, and calcine it in a Cornish or Hessian crucible, at a moderate red heat, for fifteen or twenty minutes, stirring it repeatedly with an iron rod flattened at the end. During this operation the ore will increase considerably in bulk, and it should never be continued after this begins to diminish. Having taken out the crucible in order to allow it to cool, fill the furnace† with fuel, and put on the cover to increase the heat. When cool, mix the ore, without taking it out of the crucible, with about 400 grains of the prepared flux, and cover the surface of the mixture with common salt; introduce it into the furnace, and continue it therein, at a white heat, until the whole is well melted, which will be known by the surface of the mass assuming a smooth and quiet aspect. If the furnace is in good condition, this will generally be effected in about twenty minutes. Should the operator have reason to think that the mixture in the crucible has not melted thin, so as to allow the metallic regulus to subside through the slag, he may project upon it a mixture of a scruple each of nitre, borax, and argol; and this may be again repeated if necessary, adding, however, ten grains of flowers of sulphur. When thoroughly melted, pour the contents of the crucible into a hemispherical iron mould, previously warmed and greased; allow it to become solid, and then quench it in water. Separate the button of regulus from the slag with a small hammer; it ought to be round and well defined, of a reddish-brown colour with shades of blue, or else bluish-white. When of the former colour, it contains a little more sulphur than the latter. Should the button of regulus exhibit a brilliant bluish-white surface, the slag should be remelted with two drachms of red argol, and a scruple each of slaked lime and sulphur, which will give a small button of regulus to be added to the former. It may here be remarked, that a button of regulus with a nucleus of metallic copper should always be rejected, and a fresh assay commenced, calcining the ore less. And if, when the slag and button of regulus are quenched in water, it renders the latter immediately turbid and of a dirty orange-yellow colour, it should also be rejected, the ore in this case also having been too much calcined, or too large a quantity of nitre used. On the contrary, if the regulus does not collect in a compact well-defined button, but spreads under the slag a considerable way up the sides of the mould, and of a dull-brown aspect, the ore has not been sufficiently calcined.

The regulus must now be calcined: for which purpose reduce it to powder, and expose it in a clean porcelain crucible to a very dull red heat, constantly stirring it with a flattened iron wire. As the operation proceeds, the heat must be increased and the stirring continued, until the whole of the sulphur is dissipated. Especial care must be taken, particularly at the commencement of the operation, to prevent the regulus from clotting or sticking together, which is caused by excess of heat or want of stirring, and much retards the operation. The same remark applies also to the calcination of ores. It is of vital importance that the whole of the sulphur should be expelled in this operation, and this will be greatly facilitated by projecting gradually about twenty grains of carbonate of ammonia into the crucible towards the end of the operation.

The crucible having been removed from the furnace, and allowed to cool, add to the calcined regulus about a drachm each of borax and red argol, with a scruple of nitre, covering the whole with common salt. Melt the mixture well, and pour it into a mould as before; quench it in water, and knock off the slag (which reserve) from the metallic button. The latter is now termed coarse copper, and requires to be refined; for which purpose return the crucible to the furnace, putting into it the button of copper, upon which, when melted, project about half a drachm of flux (prepared as below), and the like quantity of common salt. Shut up the furnace for about two minutes, or until the flux is well melted, and then pour out into the mould as before. Separate the flux (which reserve) from the button; and if the

* The weight used by assayers of copper ores is 400 Troy grains, marked 100 (technically called *cents*), which is subdivided down to one, and that again to one-eighth. Ore giving a button that weighs ten three-eighths is said to produce ten three-eighths per cent., and so on. The average of all the copper ores smelted in Great Britain is about eight and a half per cent.

† The furnace used for assaying copper ores is a simple air furnace, about seven inches square and fourteen inches deep, communicating with a chimney by a lateral flue five inches wide by two deep. The fuel is coke, broken to pieces about the size of walnuts, the small sifted out. Cornish crucibles are used, and require neither stand nor cover, being kept with the mouth just above the surface of the fuel.

latter does not appear to be fine (or free from alloy), repeat the operation until it is. An unerring mark of fineness is a sinking or concavity in the centre of the upper surface of the 'assay,' or button; but so long as the upper surface is convex, it is not fine. If the button, when fine, instead of having a smooth brilliant surface, of a yellowish-red colour, exhibits a roughish surface, of a dark-red colour, and having firmly attached to it bits of a dark-red slag, the refining process has been pushed too far. The button being fine, take the slag which was reserved from melting the calcined regulus, together with the flux and slag from the refining process, and mix these with three drachms of red argol and a very little charcoal powder, and melt well in the crucible in which the refining is performed. This will give a small metallic button, which refine as before.

The flux above alluded to, which is used for refining, is prepared by burning together a mixture of three parts nitre, two parts red argol, and one part of common salt. This is best done by putting the ingredients into a large iron mortar, and stirring them with a red-hot poker until combustion ceases. The mass should be reduced to powder before it is quite cold, and preserved in a well-stopped bottle, or it will deliquesce. About half a drachm of this flux and of common salt are usually taken, and this will generally be a sufficient quantity; but as much should be used as will perfectly cover the button when it is poured into the mould, otherwise the metal will oxidise, which of course is to be avoided.

The ores of the second subdivision of sulphurets are best assayed by calcining them perfectly in the first instance, so that the first melting shall give a metallic button, instead of a regulus or sulphuret. To effect this, when the one has been calcined until the whole of the sulphur is driven off, it should be melted with a drachm each of slaked lime and fluor spar, the same quantity of borax and red argol, with a little nitre; and then proceeded with precisely as directed for calcined regulus.

Copper ores not containing sulphur, or only in very small quantity, may be calcined for a short time (a few minutes is sufficient), and melted as directed in the last section, except that the quantity of lime and fluor spar may be reduced, and some scales of iron from a smith's forge added.

Lead.—The principal ore of lead is the sulphuret, commonly called galena; but the carbonate, or white lead ore, is sometimes found in considerable quantity.

To assay the former ore: take 400 grains coarsely powdered, mix it with 100 grains of black flux, and 50 grains of cream of tartar; put the mixture into a Cornish or Hessian crucible that will hold double the quantity, plunge to the bottom of it the ends of six or eight pieces of No. 10 iron wire, and cover it with carbonate of soda to the depth of half an inch. Expose it to a bright-red heat for about ten minutes, or until the matter in the crucible has ceased to boil, and is become smooth; then withdraw the pieces of iron wire, and allow the contents of the crucible to cool. On breaking the crucible, the button of lead will be found at the bottom.

If the ore is much mixed with iron pyrites or earthy matter, a little fluor spar and borax should be added to the other ingredients.

The carbonate is best assayed by melting it with half its weight of black flux and a little cream of tartar, covering the mixture as before with carbonate of soda.

Tin.—The ores of tin are principally of two kinds, the oxide and the sulphuret; the latter is, however, very rare.

To assay the oxide of tin, or black tin, as it is commonly called, it requires only simple fusion with half its weight of black flux, one-eighth borax and the like of cream of tartar, covering the mixture in the crucible to the depth of half an inch with carbonate of soda.

The sulphuret, or pyritous tin ore.—Let 400 grains be reduced to powder and carefully calcined, with occasional additions of small portions of charcoal powder, constantly stirring it with an iron rod, and so managing the fire as to prevent the ore from clotting. This operation should be continued until the ore ceases to emit either sulphureous or arsenical vapours. When thoroughly calcined, file off from the stirring-rod any portion of the ore that may adhere to it, adding it, of course, to that in the crucible. Add likewise 40 grains of lime, 20 grains of fluor spar, 150 grains of black flux, with a small quantity of nitre, borax, and cream of tartar; when these are well mixed, cover with carbonate of soda, and when melted quite smooth, allow the crucible to cool, when the tin will be found at the bottom.

Zinc.—The ores of zinc are of two kinds, the carbonate, or calamine, and the sulphuret, or blende.

There is perhaps no mode of directly assaying the ores of this metal, so as to obtain their metallic contents. That generally given in books of chemistry and metallurgy, namely, distillation of the roasted ore mixed with charcoal in an earthen retort, will be found universally to fail, either entirely or partially. Even in the treatment of these ores in the large way, the quantity of metal obtained seldom exceeds one-half the quantity which they contain: the loss arises partly from the escape of uncondensed metallic vapour, and partly from unreduced oxide.

The best mode of making comparative assays of the ores of zinc is as follows: If the ore is the carbonate, or calamine as it is usually termed, reduce it to pieces of the size of hazel-nuts, weigh thirty-two ounces, avoirdupois, and expose it under a muffle, or in a large crucible, to a moderate red heat, until the pieces are red-hot throughout. When cold reduce the ore, which will have become very friable, to a fine powder; reweigh it and note its weight, mix it with its own bulk and one-half more of powdered charcoal, and press it down moderately tight into a Stourbridge-clay crucible, which it should not fill nearer than two inches to the top. Then take a piece of moistened and tempered clay, in which a little charcoal powder and sand have been mixed, roll it out to one-eighth of an inch thick, and cut out of it a round cake to fit into the crucible upon the mixture of calamine and charcoal, giving it a little concavity on its upper surface. Then weigh as much granulated copper as is equal to two-thirds of the *calcined* calamine, spread it upon the disc of clay in the crucible, cover it with charcoal powder, and lute a clay cover to the crucible. Set the crucible in an air furnace, and expose it to a bright-red heat for three hours, and then increase the heat to a yellowish-white for another hour; then take out the crucible and allow it to cool, collect the brass which will have formed on the clay disc and weigh it; if its weight equals that of the *calcined* calamine, the latter may be considered of good quality for commercial purposes. The arrangement may be varied by mixing the granulated copper with the calamine and charcoal, instead of putting it on the clay disc; but when the operation is finished, it will be more trouble to collect the grains of brass.

This is an operation that requires considerable nicety in the management of the fire; for if too hot, the metallic zinc is vaporised faster than the copper can combine with it; and, on the other hand, if not hot enough, the oxide will not be reduced. Attention to a few trials will give the requisite judgment.

The sulphuret, or blende, is assayed in the same way, except as to calcination.

Blende must first be reduced to a fine powder and carefully calcined upon the floor of a muffle so heated as to exclude any carbonaceous smoke or flame, stirring it constantly with an iron rod until it ceases to give any indication of sulphur. The powdered blende should not lie above one-fourth of an inch thick on the muffle, and the heat should be very gradually raised from a dull to a bright-cherry red. When perfectly calcined, it must be treated in the same way as calcined calamine.

Zinc ores can only, however, be accurately assayed by the humid process. Mitchell recommends the following methods of conducting this operation: The calcined ore "is dissolved in excess of hydrochloric acid, evaporated to dryness, and redissolved by water. Some silica remains which has not been dissolved, and which may be collected on a filter. An excess of ammonia is now poured into the solution, and the precipitate separated by filtration from the solution, which latter contains all the oxide of zinc. The solution may now be boiled with an excess of carbonate of soda, until all the ammonia has been expelled, the precipitated carbonate of zinc collected on a filter, washed, dried, ignited, and weighed; four-fifths of its weight corresponds to metallic zinc.

"The analysis of *blende* may be conducted by treating it with gently warmed strong nitric acid; decant the solution with care, and boil with aqua regia; collect the residue on a filter, and wash. The solution may be treated exactly as in the analysis of calaminiferous ore: with ammonia, and carbonate of soda.

"Brass may be analysed by solution in nitro-hydrochloric acid, evaporation to dryness, treating with hydrochloric acid, diluting with water, and precipitating its contained copper by means of a rod of iron, collecting, washing, drying, and weighing the precipitated metal: the loss is zinc.

"This is only applicable, however, where the brass contains only copper and zinc; it sometimes, however, contains lead."

ASSEMBLY OF DIVINES. [WESTMINSTER ASSEMBLY.]

ASSENT, ROYAL. When a bill has passed through all its stages in both houses of parliament, if it is a bill of supply, it is sent back to the charge of the officers of the House of Commons, in which it had of course originated; but if not a bill of supply, it remains in the House of Lords. The royal assent is always given in the House of Lords, the Commons, however, being also present at the bar, to which they are summoned by the Black Rod. The sovereign may either be present in person, or may signify the royal assent by letters patent communicated to the two houses by commissioners. Power to do this is given by 33 Henry VIII. c. 21. The commissioners are usually three or four of the great officers of state, and sit in their robes on a bench placed between the woolsack and the throne. The sovereign, when the royal assent is given in person, is seated on the throne robed and crowned. The bills that have been left in the House of Lords lie on the table; the bills of supply are brought up from the Commons by the Speaker, who, in presenting them, especially at the end of a session, usually accompanies the act with a short speech. In these addresses it is usual to recommend that the money which has been so liberally supplied by the faithful Commons should be judiciously and economically expended; and a considerable sensation has been sometimes made by the emphasis and solemnity with which this advice has been enforced upon the royal ear. The royal assent to each bill is announced by the clerk of parliament. Having read the title, he says, if it is a bill of supply, "Le roi (or la reine) remercie ses loyal subjects, accepte leur benevolence, et ainsi le veut;" if any other public bill, "Le roi (or la reine) le veut;" if a private bill, "Soit fait comme il est desiré." What is called an act of grace, that is, an act by which the royal favour or bounty is extended to any party, must be signed by the sovereign before it is laid before parliament, where it is only read once in each house, and where, although it may be rejected, it cannot be amended. To such an act there is no further expression of the royal assent, but, having read its title, the clerk of the parliament says, "Les Prelats, Seigneurs, et Commons, en le present parliament assemblés, au nom de touts vos autres subjects, remercient tres humblement votre majesté, et prient a Dieu vous donner en santé bone vie et longue."

When the royal assent is refused to a bill, the form of announcement is "Le roi (or la reine) s'avisera." It is probable that in former times these words were intended to mean what they express, namely, that the sovereign would take the matter into consideration, and merely postponed his decision for the present. There has been no instance of the rejection by the crown of any bill, certainly not of any public bill, which had passed through parliament, for many years. It is commonly stated, even in books of good authority, that the last instance was the rejection of the bill for triennial parliaments by William III. in 1693. Tindal, in his continuation of Rapin, says, "The king let the bill lie on the table for some time, so that men's eyes and expectations were much fixed on the issue of it; but in conclusion he refused to pass it, so the session ended in an ill humour. The rejecting a bill, though an unquestionable right of the crown, has been so seldom practised, that the two houses are apt to think it a hardship when there is a bill denied." But another instance occurred towards the close of the same year, which was more remarkable, in consequence of its being followed by certain proceedings in parliament, which was sitting at the time. This was the rejection of the bill commonly called the Place Bill, the object of which was to exclude all holders of offices of trust and profit under the crown from the House of Commons. It was presented to the king along with the land tax bill; and the day after he had assented to the one and rejected the other, the House of Commons, having resolved itself into a grand committee on the state of the nation, passed the following resolution:—"That whoever advised the king not to give the royal assent to the act which was to redress a grievance, and take off a scandal upon the proceedings of the Commons in parliament, is an enemy to their majesties and the kingdom; and that a representation be made to the king, to lay before him how few instances have been in former reigns of denying the royal assent to bills for redress of grievances; and the grief of the Commons for his not having given the royal assent to several public bills, and in particular to this bill, which tends so much to the clearing the reputation of this house, after their having so freely voted to supply the public occasions." An address conformable to the resolution was accordingly presented, to which the king returned a polite answer, confining himself to the confidence that ought to be preserved between himself and the parliament, but taking no notice of what was said about the rejection of the bill. When the Commons returned from the royal presence, it was moved in the house "That application be made to his majesty for a further answer;" but the motion was negatived by a majority of 229 to 28.

Mr. Hatsell, in the second volume of his 'Precedents' (ed. 1818), quotes other instances of subsequent date to this; the latest being the rejection of a Scotch militia bill in 1707. In former times the refusal of the royal assent was a common occurrence. Queen Elizabeth once at the end of a session, out of ninety-one bills which were presented to her, rejected forty-eight.

It is the royal assent which makes a bill an act of parliament, and gives it the force of a law. As by a legal fiction the laws passed throughout a whole session of parliament are considered as forming properly only one statute (of which what are popularly called the separate acts are only so many chapters), it used to be a matter of doubt whether the royal assent, at whatever period of the session it might be given, did not make the act operative from the beginning of the session, when no day was particularly mentioned in the body of it as that on which it should come into effect. In order to settle this point, it was enacted by 33 Geo. III. c. 13, that the clerk of parliament should for the future endorse on every bill the day on which it received the royal assent, and that from that day, if there was not in it any specification to the contrary, its operation should commence.

It appears that the several forms of words now in use are not, as has been sometimes stated, exactly the same that have been employed in this ceremony from the first institution of parliaments. For instance, it is recorded that Henry VII. gave his assent to the bill of attainder passed in the first year of his reign (1485) against the partizans of Richard III. in the more emphatic terms, "Le roy le voet, en toutz pointz." On some occasions, of earlier date, the assent is stated to have been given in English. Thus, to a bill of attainder passed against Sir William Oldhall in 1453 (31 Henry VI.), the clerk is recorded in the Rolls of Parliament to have announced his majesty's assent as follows: "The king volle that it be hadde and doon in maner and forme as it is desired." And in 1459, in the case of an act of attainder against the Duke of York, the Earls of Salisbury, Warwick, and others, the same king gave his assent in the following form: "The king agreeth to this act, so that by virtue thereof he be not put from his prerogative to shew such mercy and grace as shall please his highness, according to his regalitie and dignitie, to any person or persons, whose names be expressed in this act, or to any other that might be hurt by the same."

In the time of the Commonwealth, an English form was substituted for those in Norman-French, which had been previously and are now in use. On the 1st October, 1656, the House of Commons resolved "that when the Lord Protector shall pass a bill, the form of words to be used shall be these, 'The Lord Protector doth consent.'" In 1706, also, a bill passed the House of Lords, and was read a second time in the House of Commons, for abolishing the use of the French tongue in all proceedings in parliament and courts of justice, in which it was directed, "that instead of 'Le roy le veult,' these words be used, 'The king answers Be it so;' instead of 'Soit fait come il est desiré,' these words be substituted, 'Be it as is prayed;' where these words, 'Le roi remercie ses bons sujets, accepte leur benevolence, et ainsi le veult,' have been used, it shall hereafter be, 'The king thanks his good subjects, accepts their benevolence, and answers Be it so;' instead of 'Le roi s'avisera,' these words, 'The king will consider of it,' be used." "Why this bill was rejected by the Commons," says Hatsell, "or why its provisions with respect to proceedings in parliament were not adopted in an act which afterwards passed in the year 1731, 'That all proceedings in courts of justice should be in English,' I never heard any reason assigned." For further information on this subject, see Hatsell's 'Precedents,' vol. ii. pp. 338—351, ed. 1818.

ASSESSMENT OF DAMAGES takes place on a writ of inquiry before the sheriff or his deputy, and a jury of the county where an action is laid, in cases where the defendant suffers judgment by default. In such cases, the defendant having admitted his liability for the debt or damage sued for, the only question is as to the amount; and the jury are summoned merely to assess the damages, and not as on trials where issue is joined to try the issue *as well as* to assess the damages (*tam ad triandum quam ad inquirendum*). The verdict may be set aside on motion to the court where the action is brought, in case the jury are improperly returned, or the sheriff has misdirected them in point of law, or the damages are excessive. [WRIT OF INQUIRY; DAMAGES.]

ASSESSMENT OF TAXES. [TAX, TAXATION.]

ASSETS (from the Norman French *assetz*, sufficient) is the real and personal property of a party deceased, which, either in the hands of his heir or devisee, or of his executor or administrator, is chargeable with the payment of his debts and legacies. Assets are either *personal* or *real*. The former, embracing goods, chattels, debts, &c., devolve on the executor or administrator; and the latter (including all real estate) descend to his heir-at-law, or are devised to his devisee. Assets are also distinguishable into *legal*, or such as render the executor or heir liable to a suit at common law on the part of a creditor; and *equitable*, or such as can only be rendered available by a suit in a court of equity, and are subject to distribution and marshalling among creditors and legatees, according to the peculiar equitable rules of that court.

1. As to *personal legal assets*. These include all goods, chattels, and moveables, which belonged to the deceased in *action* or *possession* at the time of his death, and which actually come to the executor's or administrator's hands; and also all things which come to the executors or administrators at any time *in lieu* of them. Thus, a lease made to executors, in pursuance of a covenant to grant a lease to the testator in his life; goods delivered to executors under a contract to deliver them to a testator; damages recovered by an executor for breach of a contract made with the testator, are *personal legal assets*. So the young of sheep or cattle of the testator born after his death; the profits made by his executor in carrying on his trade; the value of his mortgaged chattels, redeemed by the executor after his death, are assets of this description.

The locality of the property, in general, does not affect the question whether it is assets or not; it being a maxim that "assets in any part of the world are assets in every part of the world." Therefore, stock in foreign funds, or a leasehold for years in Ireland, must, in the case of a deficiency of assets in this country, be sold by the executor to satisfy the creditors. By the 5th Geo. II. c. 7, s. 4, houses, lands, negroes, &c., in the plantations of the West Indies, were rendered personal assets, devolving on the executor for satisfaction of debts. And the 9th Geo. IV. c. 33, produced the same operation on all real estates of British subjects (not being Mohammedans or Gentoos), situate in India within the civil jurisdiction of the British supreme courts at Fort William (Calcutta), Fort St. George (Madras), and Bombay.

As the law protects an executor or administrator from any personal charge so long as he acts rightfully, the assets which render him chargeable to a creditor are, of course, only such as *come to his hands*, and not necessarily all those of which the deceased may die possessed. It was said by Wentworth, a considerable authority on this subject, that if the testator at his death has sheep in Cumberland, bullocks in Wales, fat oxen in Bucks, money, household stuff, and plate in London, and the executor dwells at Coventry, namely, far from all these places, the executor has such an actual possession immediately on the testator's death, that he may maintain trespass against any one taking them away, and therefore it is doubtful whether these goods must not be considered to have actually come to his hands so as to be assets rendering him chargeable for payment of debts. But it seems now to be the better and more just rule, that if such property should be abstracted by any stranger, either before it has been actually possessed by the executor or afterwards, so that it be without any fault of the executor, he will only be liable to account for the damages which he may actually recover against such stranger, notwithstanding such damages may be less than the actual value of the goods. And upon the same principle, goods stolen from the possession of the executor, without blame on his part, will not be considered assets, unless indeed he have neglected an opportunity of selling them for a good price. As to all such personal property of the testator as is merely in *action*, namely, debts and rights of suit, it only in general becomes assets when reduced into possession by the executor; but if he release any such claims, or take a bond for them to himself personally, they then become assets with which he is chargeable. As nothing but what is of pecuniary value is assets, if the deceased were entitled to the next presentation to a living, and died without presenting, the right in the hands of the executor would not be assets, because not legally saleable. It follows from the very definition of *assets*, that they do not embrace property which the testator possesses merely as a trustee, without having any personal beneficial interest therein; and upon the same principle, the executor cannot employ as general personal assets property which is in the testator's hands clothed with a specific trust or appropriation; for instance, bills or notes remitted to the testator to meet acceptances for any particular purpose; nor money received by the executor himself under a specific trust to apply it in payment of his testator's debts.

2. *Personal equitable assets* are such as can only be made available by the help of a court of equity, and which consequently cannot be given in evidence against an executor on his *plene administravit* in a court of law. The distinction between the two classes is most important, and consists not merely in the mode of obtaining payment out of them by a creditor, but also in the scheme of their distribution for payment of debts. While legal assets must be applied in payment of debts, according to certain rules of priority (namely, 1. Funeral charges, &c.—2. Debts to the crown—3. Judgments—4. Recognisances, &c.—5. Rent and specialty debts, as mortgages, bonds, &c.—6. Simple contract debts—7. Legacies), equitable assets are distributable among all creditors equally, the only distinction recognised in courts of equity being that *debts* are to be preferred to *legacies*. Equitable assets embrace money produced by sale of the testator's real estate, whether his interest in such estate were legal or equitable, and whether it be expressly devised to be sold for payment of debts or not; and the equity of redemption of a mortgage is equitable and not legal assets. So also is any fund over which a man has a general power of appointment, which he exercises; in which case the property will be equitably subject to the claims of his creditors, in preference to those of his legatees or appointees.

3. *Real assets* comprise all such lands, tenements, &c., as descend to the heir at law of the deceased, and which at common law rendered him chargeable with specialty debts binding the heir. They embrace many things not strictly of a real nature. Thus an annuity, though a personal thing, is, if granted to a man and his heirs for ever, real assets, which descend to the heir; and this is also the case with things accessory to real estate, such as chimney-pieces, wainscots, doors, and other fixtures; and even deer in a park, hares and rabbits in a warren, fish in a private pond or fishery, are held to participate in the nature of real estate, and to descend to the heir as real assets. By the statute 29 Car. II. c. 3, estates *pur auter vie*, limited to the grantee and his heirs, or his heirs, executors, and administrators, during the life of a third party, are declared to be real assets in the hands of the heir. Terms of years being personal chattels, are in general personal assets in the hands of the executor or administrator; terms created or assigned over *to attend the inheritance* (according to the mode formerly used by conveyancers of protecting the inheritance from judgments and personal charges of the owner) followed the nature of the inheritance.

At common law, it was strictly only the real estate *descended* to the heir which was liable to any of his debts, and this only to debts by bond or specialty, in which the heir was specifically named. If, therefore, the debtor, after the Statute of Wills, 12 Henry VIII. c. 1, *devised* away his lands, his creditors were entirely defrauded of their debts. To remedy this evil, the 3rd Will. and Mary, c. 14, s. 2, rendered such devises void as against creditors by bond or specialty in which the heir was bound, and enabled all such creditors to sue the devisee of the land jointly with the heir at law. And this act having been construed to apply to the case of creditors on *bond* only, has been wisely repealed, and the same provisions extended by the 1st Will. IV. c. 47, to creditors, not only on bonds, but on covenants, and all other specialties. But it is not merely all classes of *specialty* creditors that have now a remedy against the real assets of the debtor: the creditors by simple contract obtained such a remedy by the 47th Geo. III. st. 2, c. 74 (re-enacted by 1 Will. IV. c. 47); but this was confined to cases where the debtor, at the time of his death, was a *trader;* and none of the above provisions applied to copyhold estates. But now, by the comprehensive enactment of 3 & 4 Will. IV. c. 104, all the real estate of the debtor, whether *freehold*, *customary*, or *copyhold*, which he shall not, by his last will, have charged with payment of his debts, is rendered assets, to be administered in courts of equity for payment of his debts, as well those due on *simple contract* as on *specialty;* provided that in the administration of assets in courts of equity creditors by specialty in which the heir is bound shall be preferred to creditors by simple contract, or by specialty, in which the heirs are not bound. It is to be observed that this important enactment confines the remedy of simple contract creditors against the real estate to a court of equity, and does not enable a simple contract creditor to sue the heir or devisee at law.

We have hitherto treated of assets merely as regards the rights and claims of the creditor against the executors and administrators, and heirs and devisees of the debtor, in respect of assets personal or real come to their respective hands. It remains to notice the doctrine of the *exoneration of the real estate*, that is, the apportionment of the debtor's liabilities in a court of equity between the two funds of the deceased, the real and the personal estate, and also the *marshalling of assets*, in order to produce a full satisfaction of all creditors. Although a creditor by specialty has, where the deceased leaves both personal and real estate, his choice of remedies either against the one or the other, so that if he sue the heir at law he cannot be met by a plea that the deceased has left personal assets, yet it is a settled rule that the personal estate in the hands of the executor or administrator is the primary and natural fund for the payment of the debts of the deceased, of whatever description. If the creditor, therefore, proceeds against the real estate, descended or devised, the heir or devisee who has sustained the loss shall be allowed to stand in the place of the specialty creditor, and reimburse himself out of the personal estate in the hands of the executor; provided, of course, that such reimbursement will not prejudice any *creditor* of the deceased: and where the exoneration of the real estate is in favour of the *heir*, it must not disappoint the claim of any legatee, except the residuary legatee, nor the wife's claim to paraphernalia. But a devisee stands in a different situation from the heir; and if he is compelled to pay a bond debt of the devisor, it seems he is entitled to reimbursement out of the personal assets, to the disappointment of general legacies, and even (as it would appear) of specific legacies.

To entitle the heir or devisee to this exoneration out of the personal estate, the debt must be the *proper* debt of the deceased; for if it was a debt charged on the estate when the deceased purchased it, or a debt incurred for money borrowed to pay off then existing charges (whether debts or legacies), the land is then the proper fund for its discharge, and the heir or devisee must take the land *cum onere*, and cannot throw the burden on the personal funds. The rule is the same with respect to both debts and legacies, namely, that the personal estate is the primary and natural fund out of which they are to be paid, and that the real estate is only to be resorted to in aid of the personalty; and even though debts and legacies are, by the will, effectually charged on the real estate, this is only taken for a declaration by the testator that the real estate shall be liable in case of a deficiency of personal assets. But though it requires more than a mere charge of the real estate to exempt the personalty, still a testator is not debarred, if his intention be sufficiently expressed, from effecting such an exemption. As to the mode of expression in a will requisite to operate this effect, the cases have been very numerous and contradictory, and evidence *dehors* the will has been, in some of them (as it is now held, improperly), resorted to. In earlier cases it was held that *express* words were requisite; but it is now settled that the personal assets will be exempted, if there appear, from the whole testamentary disposition taken together, sufficient to convince a *judicial* mind that the testator meant not merely to charge the real estate, but so to charge it as to exempt the personalty.

Marshalling assets is that operation by a court of equity, by which claimants entitled to claim against both the real and personal estate of the deceased are compelled so to elect as not to defeat the claim of other claimants who have only one of these funds to resort to. It is a general rule of equity that if A. have two funds to resort to for his debt, B., having a claim on only one of these funds, may compel A. to have recourse to the other, provided it be necessary for the satisfaction of both. The doctrine and practice of marshalling assets as between creditors by *simple contract* and creditors by *specialty*, seems to be in a great degree superseded by the effect of the statute 3 & 4 Will. IV. c. 104 (before stated), by which the former have acquired a claim against the freehold and copyhold as well as against the personal property of the deceased debtor. But the same rule of equity exists also in favour of *legatees*, and therefore if a creditor by bond, in which the heir is named, exhaust the personal estate instead of resorting to the heir, so as to leave nothing for payment of legacies, a legatee shall stand in the place of such bond creditor against the real assets *descended* to the heir. But if the real estate were devised to a stranger, it would be otherwise, for in that case it would not be equitable that a general legatee (nor as it seems a specific legatee) should obtain his legacy by throwing the specialty debts upon the *specific devisee* of the land. The principle of course applies as between a legatee and a simple contract creditor, where the latter has a claim upon the real assets, which the former has not; as where the testator's estate is generally devised charged with debts but not with legacies. [EXECUTORS, LEGACIES WILLS AND TESTAMENTS.]

(Williams's *Treatise on the Law of Executors and Administrators;* Bacon's *Abridgment* (7th ed.), tit. *Executors and Administrators, Legacies Mortgage.*)

ASSIDIANS (חֲסִידִים Chasidim, Ἀσιδαῖοι, 1 Maccab. vii. 13. Chasidaer, *the pious*), from the root חָסַד, or rather from חָסֵד, a term used to denote either a very good or a very bad action, but more frequently the former. They formed a sect among the Jews, distinguished by their more than common attention to the ceremonials of their religion. They paid more than the usual tribute to the temple, and swore by it, for which our Saviour reproved the Pharisees (Matt. xxiii. 16), who sprang from them, as the Essenes issued from the Pharisees. It was a name given to the zealous defenders of the unity of the Deity and the belief of their ancestors, against the attempts of Antiochus Epiphanes and his successors to force the Jews into idolatry. The Assidians, or Chasidim, of those days, found a leader in Mattathias, who gave the signal for armed resistance against the Syrian tyrants, by killing the commander of the king's troops at the idolatrous altar in Modim, near Joppa. Mattathias headed the Chasidim during four years against the Græcomania of those days. These four years are not included by Josephus in the 126 years of the Asmonean dynasty, which he commences from the time at which Judas Maccabi assumed the chief command.

Later Jews called those persons Chasidim who secluded themselves from worldly occupations and pleasures, to devote their life solely to religious exercises and bodily chastisements, in the hope either of expiating their own sins or those of others, or of hastening the coming of the Messiah. These Chasidim studied the kabala, and endeavoured by their mortification of the flesh to abstract the spirit from the body, and thus have liberty to enter into communion with God and angels. They fasted frequently, and asserted that they had visions.

Solomon Maimon informs his readers in his 'Memoirs' (Berlin 1792), that some of the Chasidim died in consequence of their austerities, and that others became deranged; he also states that not a few rendered their spiritual profession subservient to their temporal aggrandisement.

About the middle of the 18th century a new sect of Chasidim arose among the Jews, who invented a more comfortable method of ascetic practice. They taught that the union of man with God was effected by contemplation, and that in order to fix the mind on God it is necessary to quicken sensation by the enjoyment of permitted indulgences. They asserted that mortification of the flesh disturbs that mental tranquillity which is necessary for the contemplation of God. These Chasidim considered that union with God subsists in common religionists only during seasons of prayer, and they taught that prayer should be performed with the greatest exertion and concentration of the mental faculties, in order to unite the praying spirit so intimately with God as to obtain power over all sublunary and celestial beings, and thus to realise all desires. The tsadik is always in communion with God.

After this sect became numerous, some of its members were considered representatives of God, and their words regarded as oracles. The influence of these representatives was based solely upon their appearance of sanctity, and not upon their mental superiority. They therefore endeavoured to bring science into disrepute.

The history of the modern Chasidim is briefly this: Israel Baalschem, that is, בַּעַל־שֵׁם. *The Lord of the name*, that is, Θεουργὸς, *Theurgos*, whom Maimon erroneously calls Joel, lived A.D. 1740, in the town of Vlussy, in the circle of Czarkow, in Poland. His partisans assert that his birth was predicted to his father by the prophet Elijah, and that his mother was a hundred years old at the time of his birth, and his father still more advanced in years. While yet in his youth, they relate that he overcame some evil spirits, or demons. Baalschem went afterwards to Medziboze, in Podolia, whence he propagated his doctrines, which are contained in a volume written by himself, and edited by his grandson, under the title ספר המרות. His testament has been published under the title צואת ריבש. His birth and miracles are described by his disciple, R. Bär Linez, in a volume entitled שבחי הבעשט, 'The Habitations of Besht.' The fifth edition was published in 1815. The word בעשט, *Besht*, is formed from the initials of בעל שם טוב, *The Lord of the good name*, or *the Lord of the name of God*.

From the word Besht, the modern Chasidim have been called Beshtians. The orthodox Rabbins opposed in vain the spread of the Chasidim or Beshtians by anathema and excommunications. Baalschem based his doctrines upon the cabalistic book of Zohar, recommending a contemplative, inactive life, and frequent bathing in spring water.

The Beshtians soon spread over Wallachia, Moldavia, Hungary, and Gallizia, in which countries they are still numerous; but their principles are not admitted among the Jews in Germany, France, and Italy. This sect a long time concealed their doctrines, and propagated their opinions rather by manuscript copies of their writings than by printed publications; but since 1817 there have been many works published by their own teachers, which, though they often contain many excellent instructions and exhortations for the leading of a moral life and refraining from evil, are too frequently ornamented with marvellous tales, miraculous cures, and mystical interpretations. Several of the tsadiks, however, have shown themselves enlightened men in their writings, and endeavoured to abolish the observance of some of the old and useless ceremonials.

After the death of Baalschem, A.D. 1760, R. Bär, of Madezicy, R. Mendel Przemislaw, and R. Melash of Lyzans, endeavoured to govern the sect; not as combined triumvirs, but by each assuming the government of his own circle, under the title of *tsadik, just* or *pious*. The title of tsadik was formerly applied to Baalschem by way of distinction, but after his death each of his three most distinguished disciples endeavoured by its assumption to vindicate his own prerogative of conversing with spirits. In conversation the disciples of Baalschem are satisfied with the title of *Abbe*, or teacher.

At the present time, every shrewd individual, well read in the Talmud and in cabalistical writers, may by hypocrisy obtain the dignity of a tsadik, even if his morals are suspected. But the descendants of Besht have more facility in obtaining this dignity, because they are a kind of hereditary nobility among the Beshtians, the richest of whom feel themselves honoured by a degree of affinity with a tsadik. Besht himself taught that by honouring the descendants of the tsadik men might induce God to send the Messiah, and that the son of a tsadik is sanctified from his conception by the holy thoughts of his father, and may be called a son of God and נועם המלך.

The tsadik has no certain salary, but is supported by voluntary gifts, for which he grants his advice to the Chasidim in all transactions of life. Whenever his advice seems to be unproductive of good, the cause is thought to be in the sinfulness of the receiver, and not in the inappropriateness of the counsel. He visits yearly their district; and in the month of October his flock visit him. In times of need or distress, also, the graves of the tsadiks are visited.

The doctrines of the Chasidim may be classed under the following three heads:—

I. אֱמוּנַת חֲכָמִים וְהִתְקַשְּׁרוּת לַצַּדִּיק *faithfulness to wise men and attachment to the tsadik.*

II. דְּבֵקוּת לַשְּׁכִינָה *cleaving to the Shechinah.*

III. עזות *courage.*

This courage may even become insolence and effrontery, so that the Chasid may contradict the principles of truth, justice, equity, moderation, and decency, whenever these principles are in collision with the will of the tsadik and that of his sect.

In modern times the Chasidim have left off the use of prayer-books according to the German and Polish ritual, and have adopted the Spanish and Oriental ritual, with which they have mixed many cabalistic elements.

It is the duty of the Chasid to shout during prayer, to clap his hands loudly together, or to beat the wall with his hands, to jump about, and to move the body as in convulsions. Whoever shouts during prayer with all his might, shakes his whole body, and claps his hands, averts the wrath of God and strengthens his own memory. The Chasid must not be prevented by the ridicule of others from obeying in this respect the precepts of the tsadik.

The Chasidim do not like to assemble in the common synagogues. In every place where ten Chasidim reside they have a room called klossel (clausa) for prayer and conversation both sacred and profane. The Chasidim bathe frequently.

(*Geschichte der Lehren und Meinungen aller bestandenen und noch bestehenden religiosen Secten der Juden, und der Geheimlehre oder Kabbalah*, von Peter Beer, Brünn, 1823; Meyer's *Grosse Conversations Lexikon*, 1844, art. *Chäsidim*.)

ASSIENTO TREATY. [TREATIES, CHRONOLOGICAL TABLE OF.]

ASSIGNAT. One of the earliest financial measures of the Constituent Assembly, in the first French revolution, was to appropriate to national purposes the landed property of the clergy, which, upon the proposition of Mirabeau, was by a large majority declared to be at the disposition of the state. (Thiers, 'Histoire de la Révolution Française.') Shortly afterwards, the Assembly, desirous to profit by this measure, decreed the sale of lands belonging to the crown and the clergy, to the amount of 400 millions of francs, or about sixteen millions sterling. To sell at once so large a portion of the surface of France, without lowering the price of land by overloading the market to such an unexampled extent (Thiers), and moreover in a time of mistrust, insecurity, rapid political change, and almost of civil war, was an object of no very easy attainment. It was first proposed that the lands should be transferred to the municipalities, which, not being provided with ready money, might give the state a bond or security for the price, and the state would pay its creditors with these securities, which could, in process of time, be realised, as the municipalities were able successively to sell, at an advantageous price, the lands thus made over to them. The holders of the securities would thus have a claim not on the government, but on the municipal bodies, which would be compellable by process of law to pay; and the creditor might moreover extinguish the debt by buying the lands when put up to sale, and by offering the security in payment. But it might happen that the holder of such securities would be unable to realise them, and might not be willing to purchase any of the lands of the state; in order therefore to obviate this objection to the securities in question, it was proposed that they should be transferable and be made a legal tender.

There was also another motive for the adoption of this latter expedient. In consequence of the want of confidence and stagnation of trade which prevailed in France at this time, money had become extremely scarce, and much of the current coin had been withdrawn from circulation. The king and queen had been forced to send their plate to the mint. (Thiers, vol. i. p. 100.) Under these circumstances, it was determined to issue a paper money, based on the security of the unsold lands belonging to the state. The notes thus issued (each of which was for 100 francs, equal to 4*l.*) were called *assignats*, as representing land which might be transferred or *assigned* to the holder; and all notes which came back in this manner to the government in payment for national lands were to be cancelled. They moreover bore an interest by the day, like English exchequer bills. The object of this measure was, therefore, to obtain the full value of the confiscated lands of the clergy (which in the actual state of France was impossible), and to supply the deficiency of coin in the circulation (arising from a feeling of insecurity) by a forced issue of inconvertible paper money, which, as was predicted by M. de Talleyrand, the bishop of Autun, would inevitably be depreciated, and cause misery and ruin to the holders of it. (Thiers, vol. i. pp. 233–37, and note xviii. p. 382). The first issue of assignats was to the amount of 400 millions, bearing interest. Shortly afterwards, 800 millions in addition were issued, but without the liability to pay interest (ib. p. 256). The last of these issues was made in September 1790. But, as in the beginning of the following year, the Legislative Assembly sequestered the property of all the emigrants, a numerous and wealthy class, for the benefit of the state (Thiers, vol. ii. p. 51), it was thought that the amount of the national securities having been increased, the issues might be safely increased likewise. Accordingly, in September 1792, although 2500 millions had been already issued, a fresh issue to the amount of 200 millions was ordered by the Convention. (Thiers, vol. iii. p. 151.) Towards the end of this year, the double effects of the general insecurity of property and person, and of the depreciation of assignats caused by their over-issue, was felt in the high price of corn, and the unwillingness of the farmers to supply the markets with provisions. Wholly mistaking the causes of this evil, the violent revolutionary party clamoured for an assize, or fixed maximum of prices, and severe penalties against *accapareurs*, or engrossers, in order to check the avarice and unjust gains of the rich farmers. The Convention, however, though pressed both by factious violence and open insurrection, refused at this time to regulate prices by law. (Thiers, vol. iii. pp. 311–17.) Prices however, as was natural, still continued to rise; and although corn and other necessaries of life were to be had, their value, as represented in the depreciated paper currency, had been nearly doubled. The washerwomen of Paris came to the Convention, to complain that the price of soap, which had formerly been fourteen sous, had now risen to thirty. On the other hand, the wages of labour had not risen in a corresponding degree (see Senior on 'Some Effects of Government Paper,' p. 81); so that the evils arising from the depreciation of the assignats greatly aggravated the poverty and scarcity which would, under any circumstances, have been consequent on the troubles and insecurity of a revolution. The labouring classes accused the rich, the engrossers, and the aristocrats, of the evils which they were suffering, and demanded the imposition of a maximum of prices. Not only however in the Convention did the most violent democrats declare loudly against a maximum, but even in the more popular assembly of the Commune, and the still more democratic club of the Jacobins, was this measure condemned, frequently amidst the yells and hisses of the galleries. As the Convention refused to give way, Marat, in his newspaper, recommended the pillage of the shops as a means of lowering prices—a measure immediately adopted by the mob of Paris, who began by insisting to have goods at certain fixed prices, and ended by taking the goods without paying for them. (Thiers, vol. iv. pp. 38–52.) These and other tumults were however appeased, partly by the interference of the military, and partly by the earnest remonstrances of the authorities. But the evil still went on increasing; corn diminished in quantity and increased in price; the national lands, on account of the uncertainty of their title and the instability of the government, were not sold, and thus the number of assignats was not contracted, and they were continually more and more depreciated.

At length the Convention, thinking that the depreciation might be stopped by laws, made it penal to exchange coin for paper, or to agree to give a higher price if reckoned in paper than if reckoned in coin. Still the over-issue had its natural effects: in June 1793, one franc in silver was worth three francs in paper; in August it was worth six. Prices rose still higher; all creditors, annuitants, and mortgagees were defrauded of five-sixths of their legal rights; and the wages of the labourers were equal in value only to a part of their former earnings. The Convention, unable any longer to resist, in May 1793 passed a decree which compelled all farmers to declare the quantity of corn in their possession, to take it to the markets, and sell it there only, at a price to be fixed by each commune, according to the prices of the first four months of 1793. No one was to buy more corn than would suffice for a month's consumption, and an infraction of the law was punished by forfeiture of the property bought and a fine of 300 to 1000 francs. The truth of the declaration might be ascertained by domiciliary visits. The commune of Paris also regulated the selling of bread; no person could receive bread at a baker's shop without a certificate obtained from a revolutionary committee, and the quantity was proportioned to the number of the family. A rope was moreover fixed to the door of each baker's shop, so that, as the purchasers successively came, they might lay hold of it, and be served in their just order. Many people in this way waited during the whole night; but the tumults and disturbances were so great that they could often only be appeased by force, nor were they at all diminished by a regulation, that the last comers should be served first. A similar maximum of prices was soon established for all other necessaries, such as meat, wine, vegetables, wood, salt, leather, linen, woollen and cotton goods, &c.; and any person who refused to sell them at the legal price was punished with death. Other measures were added to lower the prices of commodities. Every dealer was compelled to declare the amount of his stock; and any one who gave up trade, after having been engaged in it for a year, was imprisoned as a suspected person. A new method of regulating prices was likewise devised, by which a fixed sum was assumed for the cost of production, and certain percentages were added for the expense of carriage, and for the profit of wholesale and retail dealers. The excessive issue of paper had likewise produced its natural consequence, over speculation, even in times so unfavourable for commercial undertakings. Numerous companies were established, of which the shares soon rose to more than double or treble their original value. These shares being transferable, served in some measure as a paper currency, upon which, the Convention thinking that they contributed still further to discredit the assignats, suppressed all companies whose shares were transferable or negociable. The power of establishing such companies was reserved to the government alone.

In August 1793 there were in circulation 3776 millions of assignats; and by a forced loan of 1000 millions, and by the collection of a year's taxes, this amount was subsequently reduced to less than two-thirds: the confidence, moreover, inspired by the recent successes of the republic against its foreign and domestic enemies, tended to increase the value of the securities on which the paper-money ultimately reposed: so that towards the end of 1793 the assignats are stated to have been at par. This effect is attributed by M. Thiers, in his 'History of the French Revolution' (vol. v. p. 407), to the severe penal laws against the use of coin: nevertheless we suspect that those who made this statement were deceived by false appearances, and that neither at this nor any other time, nor even at their first issue, did the real value of assignats agree with their nominal value. (Thiers, vol. v. pp. 145-62, 196-208, 399-413.) However, this restoration of the paper-currency, whether real or apparent, was of very short duration, as the wants of the government led to a fresh issue of assignats; so that in June 1794 the quantity in circulation was 6536 millions. By this time the law of the maximum had become even more oppressive than at first, and it was found necessary to withdraw certain commodities from its operation. Nevertheless, the commission of provisions, which had attempted to perform the part of a commissariat for the whole population of France, began to interfere in a more arbitrary manner with the voluntary dealings of buyers and sellers, and to regulate not only the quantity of bread, but also the quantity of meat and wood which each person was to receive. (Thiers, vol. vi. pp. 146-51, 307-14.) Other arbitrary measures connected with the supply of the army, as compulsory requisitions of food and horses, and the levying of large bodies of men, had contributed to paralyse all industry. Thus not only had all commerce and all manufactures ceased, but even the land was in many places untilled. After the fall of Robespierre, the Thermidorian party (as it was called), which then gained the ascendancy, being guided by less violent principles, and being somewhat more enlightened on matters of political economy than their predecessors, induced the Convention to relax a little of its former policy, and succeeded in first excepting all foreign imports from the maximum, and afterwards in abolishing it altogether. The transition to a natural system was, however, attended with great difficulty and danger, as the necessary consequence of the change was a sudden and immense rise of the avowed prices; and trade having been so long prevented from acting for itself, did not at once resume its former habits; so that Paris, in the middle of winter, was almost in danger of starvation, and wood was scarcely more abundant than bread. As at this time the power of the revolutionary government to retain possession of the lands which it had confiscated, and to give a permanently good title to purchasers, was not doubted, it is evident that a fear lest the national lands might not ultimately prove a valuable security did not now tend to discredit the assignats: their depreciation was solely owing to their over-issue, as compared with the wants of the country, and their inconvertibility with the precious metals. The government, however, began now to find that, although it might for some time gain by issuing inconvertible paper in payment of its own obligations, yet when the depreciated paper came to return upon it in the shape of taxes, it obtained in fact a very small portion of the sum nominally paid. Consequently they argued that, as successive issues depreciated the currency in a regular ratio (which, however, is very far from being the case), it would be expedient to require a larger sum to be paid for taxes, according to the amount of paper in circulation. It was therefore decreed that, taking a currency of 2000 millions as the standard, a fourth should be added for every 500 millions added to the circulation. Thus, if a sum of 2000 francs was due to the government, it would become 2500 francs when the currency was 2500 millions, 3000 francs when it was 3000 millions, and so on. This rule, however, was only applied to the taxes due to the government, and was not extended to payments made by the government, as to public creditors or public functionaries. Nor did it comprehend any private dealings between individuals. (Thiers, vol. vii.) Iniquitous as this regulation was, as employed solely in favour of the government, it would nevertheless have been ineffective if its operation had been more widely extended; for the assignats, instead of being depreciated only a fifth, had now fallen to the 150th part of their nominal value. The taxes being levied in part only in commodities, and being chiefly paid in paper, produced scarcely anything to the government, which had, however, undertaken the task of feeding the city of Paris. Had it not in fact furnished something more solid than depreciated assignats to the fundholders and public functionaries, they must have died of starvation. Many, indeed, notwithstanding the scanty and precarious supplies furnished by the government, were threatened with the horrors of famine; and numbers of persons threw themselves every evening into the Seine, in order to save themselves from this extremity. (Storch, 'Economie Polit.,' vol. iv. p. 168.)

To such a state of utter pauperism had the nation been reduced by the mismanagement of its finances and the ruin of public credit by the excessive issues of paper, that when the five directors went to the Luxembourg in October 1795, there was not a single piece of furniture in the office. The doorkeeper lent them a rickety table, a sheet of letter-paper, and an inkstand, in order to enable them to write their first message to announce to the two councils of state that the Directory was established. There was not a single piece of coin in the treasury. The assignats necessary for the ensuing day were printed in the night, and issued in the morning wet from the press. Even before the entry of the directors into office, the sum in circulation amounted to 19,000 millions: a sum unheard of in the annals of financial profligacy. One of their first measures, however, in order to procure silver, was to issue 3000 millions in addition, which produced not much more than 100 million francs.

In this formidable state of things, the next measure adopted was worthy of the violent and short-sighted administration from which it emanated. A forced loan of 600 millions was raised from the richest classes, to be paid either in coin, or in assignats at the *hundredth* part of their nominal value. So that if the current paper was 20,000 millions, a payment of 200 millions would be sufficient to extinguish the whole. The government, however, refused to sanction this principle as against itself; for in paying the public creditor, it gave the assignat the *tenth* part of its nominal value. The land-tax and the duties in farm were required to be paid half in kind and half in assignats; the custom-duties, half in corn and half in assignats. In the mean time, until the funds produced by this loan, which was enforced with great severity, could be at the disposition of the state, the government went on issuing assignats, till they had absolutely lost all value, and had become waste paper. It therefore anticipated its resources by issuing promissory notes payable in specie, when the forced loan should be collected, and with difficulty prevailed on bankers to discount them to the amount of 60 millions. At this time the Directory gave up the task of supplying Paris with bread, and allowed the bakers' shops to be opened as before: an exception being made in favour of the indigent, and of fundholders and public functionaries whose annual incomes were not more than 5000 francs. The payment of the loan, however, went on slowly, the produce of the government bills was exhausted, and fresh funds were required. Again the resource of assignats was resorted to, and in two months the currency had been raised to 36,000 millions, by the issue of 20,000 millions, which even to the government were not worth the 200th part of their nominal value.

By this time some new financial expedient became necessary. It was expected that, by payments of taxes and of the forced loan to the government, the paper in circulation would soon be reduced to 24,000 millions. It was therefore determined to make a new issue of paper, under the name of *mandats*, to the amount of 2400 millions. Of this sum 800 millions were to be employed in extinguishing 24,000 millions of assignats, which were to be taken at a thirtieth part of their legal value: 600 millions were to be allotted to the public service, and the remainder retained in the public coffers. These mandats were to enable any person who was willing to pay the estimated value of any of the national lands to enter at once into possession; and therefore they furnished a somewhat better security than the assignats, as these could only be offered in payment at sales by auction; and consequently the price of the lands rose in proportion to the depreciation of the paper. The estimate of the lands having been made in 1790, was not true in 1795, at which time they had in some cases lost a half, in others two-thirds or three-fourths of their former value. The mandat of 100 francs, however, at its first issue, was worth only fifteen francs in silver; and the new paper was soon so much discredited that it never got into general circulation, and was not able to drive out the coined money which was now almost universally employed in transactions between individuals. The only holders of mandats were speculators, who took them from the government and sold them to purchasers of national lands. By this entire discredit of the government-paper the prosperity of individuals had been in some measure restored, and trade revived a little from its long sleep. The government was destitute of all resource; its agents received nothing but worthless paper, and refused any longer to do their duties. The armies of the interior were in a state of extreme misery; while those of Germany and Italy were maintained only from the countries where they were quartered. The military hospitals were shut, the gens-d'armes were not paid or equipped, and the high roads were infested with bands of robbers, who sometimes even ventured into the towns.

In a short time the government were forced to abandon the mandats, as they had abandoned the assignats, and to declare that they should be received in payment of taxes and national lands only at their real value. Having fallen to near a seventieth of their ostensible value, they were, in the course of 1796, returned to the government in payment of taxes and for the purchase of lands; and with them ended the revolutionary system of paper-money, which probably produced more wide-spreading misery, more sudden changes from comfort to poverty, more iniquity in transactions both between individuals and the government, more loss to all persons engaged in every department of industry and trade, more discontent, disturbance, profligacy, and outrage, than the massacres in September, the war in La Vendée, the proscriptions in the provinces, and all the sanguinary violence of the Reign of Terror.

From the extinction of the mandats to the present time the legal currency of France has been exclusively metallic. (Thiers, vol. viii. pp. 85-9, 103-19, 158-62, 177, 183-91, 334-44, 423-4; Storch, 'Cours d'Econ. Pol.,' vol. iv. p. 164.)

ASSIGNEE OF BANKRUPT. [Bankruptcy.]

ASSIGNEE OF BILL OF LADING. [Bill of Lading.]

ASSIGNEE OF INSOLVENT DEBTOR'S ESTATE. [Insolvent Debtor.]

ASSIGNEE OF A LEASE is the party to whom the *whole* interest of the lessee is transferred by assignment, which assignment may be made without the privity or consent of the lessor, unless the lessee is expressly restrained by the lease from assigning over. The assignee becomes liable to the lessor, from the date of the assignment, for the payment of the rent and performance of the covenants in the lease; but such liability is limited to breaches of covenant during the existence of the assignee's interest, and may be got rid of by assigning over all his interest, and this even to an insolvent; for his liability, arising only from *privity of estate*, that is, from the actual enjoyment of the premises leased, ceases with such enjoyment; whereas the lessee remains liable to the rent and covenants during the whole term. It results also from the circumstance of the assignee's liability arising from *privity of estate*, that he is not liable to mere personal covenants which the lessee may have made with the lessor (as, for example, to build on premises not demised, or to pay a sum of money in gross), but only to such covenants as run with the land, as for instance, covenants to pay rent, to repair, to reside on the demised premises, to leave part of the land in pasture, to insure premises situate within the weekly bills of mortality, to build a new mill on the site of an old one, &c. [Covenant.] The assignee, in order to become liable to the covenants, must take the whole estate and interest of the lessee; for if the smallest portion is reserved, he is merely an under-lessee, and not responsible to the original lessor. The interest of the assignee must also be a legal, not merely an equitable interest; and therefore if the lessee devise the premises leased to trustees in trust for A B, A B will not be chargeable as the assignee of the lessee's interest. The interest must also be an interest in lands or tenements; for if a lease is made of chattels (as for instance, of sheep or cows, which sometimes happens), and the lessee covenant for himself and his assigns to re-deliver them, the assignee is not liable to the owner on this covenant; for there is no privity between the assignee and the owner, such privity only existing where the subject of the demise is real estate. Wilmot, C. J., says, in *Bally* v. *Wells*, "The covenant in this case is not collateral; but the parties, that is, the lessor and assignee, are total strangers to each other, without any line or thread to unite and tie them together, and to constitute that privity which must subsist between debtor and creditor to support an action."—(Wilmot, 345.) The assignee may acquire his interest by operation of law as well as by an actual assignment from the lessee, and therefore a tenant by *elegit*, who has purchased a lease under an executor, is liable as assignee to the lessor in respect of his privity of estate. [As to the liability of assignees of bankrupt on the leases of the bankrupt, see Bankrupt.]

ASSIGNMENT, a deed or instrument of transfer, the operative words of which are usually 'assign, transfer, and set over,' and which passes both real and personal property. Estates for life and estates for years are the principal real interests which are passed by an assignment; and by the statute of Frauds and Perjuries (29 Car. II.) the assignment of such estate is required to be in writing. An assignment differs from a lease, in being a transfer of the entire interest of the lessor; whereas a lease is carved out of a greater estate, creates the relation of landlord and tenant, and reserves to the lessor a reversion after its expiration. If, however, a deed in effect passes the whole interest of the tenant, it operates as an assignment, though it be in form a lease, and though it reserve a rent. As if A having a term of twenty years in land, grants to B the whole twenty years, reserving a rent: in such case B is assignee of the whole term and interest, and not under-lessee to A; and A, for want of having any reversion, cannot distrain for the rent (a distress being only enforceable where the landlord has a reversion expectant on the determination of the tenancy). A, in such case, can only sue B for the rent as for money due upon a contract. In all under-leases, therefore, it is necessary that part (a day will suffice) of the original term should remain in the lessor. See Sheppard's 'Touchstone,' 266; Blackst. 'Comm.' vol. ii. p. 324 (Mr. Kerr's ed.); Bacon's 'Abr.' (7th edit.) tit. *Assignment.* [BILL OF SALE.]

An Assignment of Goods, Chattels, &c., is frequently made by bill of sale, as to which, see BILL OF SALE. As to all goods and chattels *in possession,* no objection ever existed to their transfer and assignment by deed or writing: but with respect to things *in action* (as debts, contracts, right of entry, and suit), according to an ancient rule of the common law, now considerably modified, they could not be assigned over by the party to whom they were due, since the assignment gave to a third party a right of action against the debtor, and thus led to the offence of maintenance—that is, the abetting and supporting of suits in the king's courts by others than the actual parties to them. In the courts of common law this rule exists (with some exceptions) at the present day. Thus, if the obligee in a bond assign over the bond to a third party, the assignee cannot sue on the bond at common law in his own name; but such an assignment generally contains (and ought always to do so) a power of attorney from the obligee to the assignee, to sue in the obligee's name on the bond. Courts of equity have always protected such assignments, and regarded the assignee, for valuable consideration, as the actual owner of the bond; and the courts of common law so far recognise the right of the assignee, that if the obligor, *after notice* of the assignment, pay the money on the bond to the obligee, the courts will not permit him to plead such payment to an action brought by the assignee in the obligee's name on the bond. In order to constitute a good equitable assignment of a bond, or chose in action, writing is not necessary. A personal trust or confidence cannot be assigned over, however able the assignee may be to execute it; and therefore all trust deeds and settlements contain express provisos for the retiring of trustees, and for fresh appointments, with the consent of the *cestui que trusts.* Neither the future whole-pay nor the future half-pay of an officer are capable of being assigned, it being considered contrary to public policy that a stipend given to a man for his public services should be transferred to another man not capable of performing them. The exceptions to the rule that *choses in action* are not assignable at law are many. The king might at all times become the assignee of a *chose in action;* and after such an assignment was entitled to have execution against the body, lands, and goods of the debtor. But this prerogative, having been abused by the king's debtors, was restrained by stat. 7 Jac. I. c. 15, by a privy seal, in 12 James I., and by rule of court of 15 Car. I.; and the practice of actually assigning debts to the king by his debtors has long become obsolete. Bills of exchange are assignable by indorsement, in virtue of the custom of merchants [BILL OF EXCHANGE]; and promissory notes, by virtue of the 3 & 4 Ann. cap. 9. Bail bonds are assignable by the sheriff to plaintiff in the suit under 4 Ann. c. 16, s. 20. [BAIL.] Replevin bonds, by the 11 Geo. II. c. 19. [BANKRUPT; BOND; CHOSE IN ACTION; INSOLVENT DEBTORS; REPLEVIN.]

ASSIZE. This word has been introduced into our legal phraseology from the French *assis,* and is ultimately derived from the Latin verb *assideo,* to sit by, or, as Lord Coke translates it, to sit together. The word *assido* is also to be found in legal records, and has in law-latin a different meaning from *assideo,* signifying to assess, fix, or ordain. Thus in the *postea,* or formal record of a verdict in a civil action, it is said that the jury find for the plaintiff, *et assidunt damna ad decem solide;* 'and they assess the damages at ten shillings;' and then the judgment of the court is given for the damages 'per juratoris in formâ prædictâ assessa.' It is possible that the word assize, in cases where it signifies an ordinance, decree, or assessment, may be derived from this word. This etymology is not, however, given by Du Cange, Spelman, or any learned writer on this subject; though it obviously leads much more distinctly to several meanings of the word assize than the derivation from *assideo.* With reference to English law, the word assize has been called by Littleton *nomen æquivocum,* on account of its application to a great variety of objects, in many of which neither the etymology of the word nor its original meaning can be readily traced. Thus, 1. The term is used to signify an ordinance or decree made either immediately by the king, or by virtue of some delegation of the royal authority. The Assizes of Jerusalem are a well-known code of feudal jurisprudence framed for the kingdom of Jerusalem, formed in 1099, under Godfrey of Bouillon. In this sense, Fleta speaks of 'the laws, customs, and *assizes* of the realm,' and the ordinances made by the great council of nobles and prelates assembled by Henry II. in 1164 and commonly known as the 'Constitutions of Clarendon,' are called by Hoveden '*Assisæ* Henrici Regis factæ apud Clarendonum.' In like manner the assizes of the forest were rules and regulations made by the courts to which the management of the royal forests belonged.

2. Analogous to these were the assizes or ordinances regulating the price of bread, ale, fuel, and other common necessaries of life; called in Latin *assisæ venalium.* The earliest express notice of any regulation of this kind in England is in the reign of John (1203), when a proclamation was made enforcing the observance of the assize of bread; but it is probable that there were more ancient ordinances of the same kind. In very early times these *assisæ venalium* appear to have been merely royal ordinances, and their arrangement and superintendence were under the direction of the clerk of the market of the king's household. But at a subsequent period many statutes were passed regulating the assize of articles of common consumption; the earliest of these is the assize of bread and ale, *assisa panis et cervisiæ,* commonly called the stat. of 51 Henry III., though its precise date is somewhat doubtful. The provisions of the act with regard to ale, establishing a scale of prices varying with the price of wheat, were altered in some measure by 23 Henry VIII. c. 4, which left a discretionary power with the justices of the peace of fixing the price of ale within their jurisdiction [ALE]; but the assize of bread was imposed by this Act, and enforced from time to time by orders of the privy council until the reign of Queen Anne. In cities and towns corporate the power of regulating the assize of bread and ale was frequently given by charter to the local authorities, and the interference of the clerk of the King's household was often expressly excluded. Books of assize were formerly published, under authority of the privy council, by the clerk of the market of the king's household, and there is one still in existence which was printed in the reign of Henry VIII. The stat. 8 Anne, c. 19, repealed the 51 Henry III. and imposed a new assize of bread, making various other regulations respecting it. Several subsequent Acts have been passed on the subject; but by the 55 Geo. III. c. 99, the practice was expressly abolished in London and its neighbourhood, and in other places it has fallen into disuse. There was also an assize of wood and coal (34 & 35 Henry VIII. c. 3); and so late as the reign of Queen Anne, we find an Act (9 Anne, c. 20) enforcing former regulations for the assize of billet. Besides these, various other articles—wine, fish, tiles, cloths, &c., have at different times been subject to assize. The object of these regulations was the prevention of fraud and monopoly; and it is not surprising that in the early stages of legislation it should have appeared to be one of the first duties of government to secure to its subjects the prime necessaries of life at a reasonable and uniform rate. But subsequent experience and more enlightened views have shown, that to attempt to fix by law the prices of commodities, is not only useless and mischievous, but in most cases impracticable; and that when government has established an uniform scale of weights and measures, and, so far as it can be done, an uniform measure of value, the rest may safely be left to competition, and to the mutual bargaining which takes place between the buyer and the seller.

3. The word assize is also used to denote the peculiar kind of jury by whom the writ of right was formerly tried, who were called the grand assize. The trial by the *grand assize* is said to have been devised by Chief Justice Glanville, in the reign of Henry II., and was a great improvement upon the trial by judicial combat, which it in a great degree superseded. Instead of being left to the senseless and barbarous determination by battle, which had previously been the only mode of deciding a writ of right, the alternative of a trial by the grand assize was offered to the tenant or defendant. Upon his choosing this mode of trial, a writ issued to the sheriff directing him to return four knights, by whom twelve others were to be elected, and the whole sixteen composed the jury, or grand assize by whom the matter of right was tried. The stat. 3 & 4 Will. IV. c. 27, has abolished this mode of trial, the cumbrous machinery of which was entirely unfit for the habits of modern society. [JURY.] The jury in criminal cases in Scotland, which is fifteen in number, are still technically called the assize.

4. The common and popular use of the term assize, at the present day in England, is to denote the sessions of the judges of the superior courts, holden periodically in each county for the purpose of administering civil and criminal justice. These assemblies no doubt originally derived their denomination from the business which was at first exclusively imposed upon them, namely, the trial of writs of assize. According to the common law, assizes could only be taken (that is, writs of assize could only be tried) by the judges sitting in term at Westminster, or before the justices in eyre at their septennial circuits. This course was productive of great delay to suitors, and much vexation and expense to the juries, or grand assize, who might have to travel from Cornwall or Northumberland, to appear in court at Westminster. To remedy this grievance, it was provided by Magna Charta, in 1225, that the judges should visit each county once in every year, to take assizes of novel disseisin and mort d'ancestor. From this provision the name of justices of assize was derived; and by several later Acts of parliament various authorities have been given to them by that denomination. The 13 Edward I. c. 3, (stat. of Westminster the second,) enacted that the justices of assize for each shire should be two sworn judges, associating to themselves one or two discreet knights of the county; and they are directed to take the assizes not more than three times in every year. By the same statute, authority is given them to determine inquisitions of trespass and other pleas pleaded in the courts of King's Bench and Common Pleas. From this important Act of parliament the jurisdiction of the judges of assize to try civil causes, other than the writs of assize above mentioned, originally arose; and as, with some modifications, it forms the basis of their civil authority at the present day, it may be desirable to endeavour to explain the complex and argumentative process by which the provisions of the statute are practically effected. Besides the general authority to determine civil issues, it was provided by the statute of Westminster 2, that no inquest in a civil action should be taken by the judges of the superior courts when sitting at Westminster unless the judicial writ

which summoned the jury for such inquest appointed a certain day and place for hearing the parties in the county where the cause of action arose. Thus, if a suit arose in Cornwall, the writ from the superior court must direct the sheriff of that county to return a jury at Westminster for the trial of the inquest in the next term, '*unless before*' (*nisi prius*) the term, namely on a certain day specified in the writ, the justices of assize came into Cornwall. This was sure to happen under the directions of a previous clause in the statute, in the course of the vacation before the ensuing term, and the jury were then summoned before the justices of assize in Cornwall, where the trial took place, and the parties avoided all the trouble and expense of conveying their witnesses and juries to London. The jurisdiction of the judges of *nisi prius* is therefore an annexation to their office of justices of assize; and thus, from the alteration in the state of society since the above laws were made, the principal or substantial part of their jurisdiction has, by the abolition of writs of assize, become merely nominal, while their annexed or incidental authority has grown into an institution of immense practical importance.

For several centuries, until a few years ago, the whole of England was divided into six circuits, to each of which two judges of assize were sent twice a year. Previously to 1830, the Welsh counties and the county palatine of Chester were independent of the superior courts at Westminster, and their peculiar judges and assizes were appointed by the crown under the provisions of several statutes. This separation of jurisdiction being found inconvenient, the statute 1 William IV. c. 70 increased the number of judges of the superior courts, and enacted that, in future, assizes should be held for the trial and despatch of all matters criminal and civil within the county of Chester and the principality of Wales under commissions issued in the same manner as in the counties of England. Since the passing of this statute, therefore, the assizes throughout the whole of England and Wales (excepting London and Middlesex, where the administration of justice is regulated by custom and Acts of parliament) have been holden twice a year in each county upon a uniform system. In addition to these ordinary assizes, a third assize for the trial of criminals has for the last ten years taken place in the more populous counties.

The judges upon the several circuits derive their civil authority ultimately from the ancient statutes of assize and *nisi prius* in the manner before described; but they have also a commission of assize which is issued for each circuit by the crown under the great seal. This commission pursues the authority originally given by Magna Charta and the statutes of *nisi prius*, and seems to have been nearly in the same form ever since the passing of those statutes. It is directed to two of the judges and to the Queen's counsel (13 & 14 Vict. c. 25), and serjeants, the latter deriving their authority to be judges of assize from the statute 14 Edward III. c. 16, which mentions "the king's serjeant sworn," under which words Lord Coke (2 Inst. 422) says that any serjeant at law is intended, and commands them "to take all the assizes, juries, and certificates, before whatever justices arraigned." Under the direct authority given by these words, the commissioners have in modern times nothing to do, the "assizes, juries, and certificates" mentioned in the commission having only a technical reference to the writs of assize, now wholly discontinued. It is stated in most of the common text books that the judges of assize have also a *commission* of *nisi prius*. This is, however, a mistake, no such commission being known in our law, and the only *authority* of the judges to try civil causes being annexed to their office of justices of assize in the manner above described.

In certain cases, the justices of assize, as such, have by statute a criminal jurisdiction; but the most important part of their criminal authority is derived from other commissions. The first of these is a general commission of Oyer and Terminer for each circuit, which is directed to the lord chancellor, several officers of state, resident noblemen and magistrates, and the queen's counsel and serjeants on their respective circuits; but the judges, queen's counsel, and serjeants, are always of the quorum, so that the other commissioners cannot act without one of them. This commission gives the judges of assize express power to try treason, felony, and a great variety of offences against the law of England, committed within the several counties composing their circuit. [OYER AND TERMINER.]

The judges of assize have also commissions of gaol delivery, which in their legal effect give them several powers, which, as justices of Oyer and Terminer only, they would not possess. They are directed to the judges, the queen's counsel, and serjeants on the circuit, and the clerk of assize and associate. Every description of offence is cognizable under this commission; but the commissioners are not authorised to try any persons except such as are in actual or constructive confinement in the gaol specifically mentioned in their commission. There is a distinct commission under the great seal for the delivery of the prisoners in each particular gaol. [GAOL DELIVERY.]

In addition to the above authorities, the judges on the circuit are also fortified by the commission of the peace. The judges of the three superior courts of common law, for the time being, are always inserted in the commissions of the peace periodically issued for each English county; and consequently they may exercise all the powers and functions communicated by the commissions of the particular counties which compose their respective circuits.

The judges on circuit have also authority to try by a jury of the county to which they are sent, issues joined in the Court of Probate and in the Court for Divorce and Matrimonial Causes. [PROBATE; DIVORCE.]

In practice, the judges of the courts at Westminster choose their circuits by arrangement among themselves on each separate occasion. They are then formally appointed by the crown under the sign manual; and the several commissions are afterwards made out in the Crown Office of the Court of Chancery from a fiat of the lord chancellor.

ASSOCIATION is one of the mental phenomena. It does not rank among the primary powers of the mind, like sensation, perception, and judgment, because it does not form one of the separate steps of all mental operations; nor do its functions consist, like those of memory, in re-embodying past impressions. It acts as an agent to all these powers, though not a power itself. The office which it performs is to connect and arrange rather than to originate ideas. By its influence over the sensations, perceptions, and judgments, it regulates the succession of the thoughts. When one thought is suggested by another, or when a train of past images is summoned by something present, whether spontaneously or by an exertion of memory, the process by which this effort is made is called association. Dr. Brown has designated it "the principle of suggestion:" a term which, if its operations were discriminative and voluntary, would be preferable to the one in present use. But suggestion implies deliberation, choice; whereas, it is the province of association to awaken perceptions, not to perceive; to link the thoughts, not to think; to lead the memory to successive images and trains of ideas, between which there is a bond of connection, not always obvious, but when discovered, traceable to one or other of those affinities, analogies, or contrasts by which the principle of association acts. Mr. Hume was the first writer who traced the influences of our associations to certain principles, which he denominated "resemblance, contiguity in time or place, and cause or effect." "Contrast" has since been added to these, which completes the classification of those sympathies and predilections, seated in the mind and acting with all the force and certainty of established laws.

It is not pretended that there may not be large classes of our associations not referable to any of these principles, such as the names of things, the terms of art, the words by which we designate moral and intellectual qualities and operations; in short, the whole vocabulary of language, in which there is little or no connection either in the way of resemblance, contiguity, cause, effect, or contrast with the objects or ideas represented, although none of them ever fail to summon up the images of the things for which they stand. Anomalies like this, when reducible to certain limits, establish rather than invalidate the laws to which they form an exception. Even the terms of a language, when once connected with their representative objects, offer one of the most remarkable illustrations of simple association. In the word *flower*, for instance, there is nothing to stamp upon the mind any particular image. To one who was ignorant of language it would convey no idea; but let the word be explained, let it once be associated with its representative genus of objects, and it instantly calls up the picture of some beautiful plant in blossom whenever the name is seen or pronounced. The distinction between association and memory is here plainly visible. The knowledge of the term *flower* is an act of memory; the knowledge of the object which it represents implies also an act of memory; but the connection between the name and the object, and still more, between the name and the particular flower that blooms before the mind's eye, are the results of association.

Mr. Hume has annexed to his enunciation of the three principles above enumerated an example illustrative of each. "That these principles," he observes, "serve to connect ideas will not, I believe, be much doubted. A picture naturally leads our thoughts to the original. The mention of one apartment in a building naturally introduces an inquiry or discourse concerning the others. And if we think of a wound, we can scarce forbear reflecting on the pain which follows it." The first of these illustrations is founded upon the law of resemblance; the second, upon the law of contiguity; the third, upon the law of causation. "But," continues he, "that this enumeration is complete, and that there are no other principles of association except these, may be difficult to prove to the satisfaction of the reader, or even to a man's own satisfaction."

To whatever principles or laws we ascribe the association of ideas, it is evident enough that there is not only a bond of connection amongst them, but a bond of order. The greatest irregularity and confusion would obviously prevail in our mental operations, without some regulating principle. That principle is association. It is to mind what the law of attraction is to matter. It draws together ideas connected by common affinities, and repels others that cannot coalesce. When we contemplate the vast number of different impressions made upon the mind in the course of every day, which have to be referred to again, what a confusion would be created, were there not some property in the ideas by which they arrange themselves according to certain invariable laws and relations, designed not only to preserve them, but to promote their restoration at a future period. This reproduction of our thoughts in so perfect a manner, in the order in which they are wanted, comprises one, and not the least remarkable, of the phenomena of association. Most of our ideas are reproduced with facility, but occasionally it is with difficulty they are recovered, owing either to indistinctness in the original impression, or to an imperfection of the associating faculty itself, which is not equally acute in every individual, nor equally active at all times in the same individual.

Sometimes trains of associations *involuntarily* convey the thoughts to subjects foreign to our wishes. They run away, as it were, with our ideas; and, regardless of the unities of time or place, awaken images and recollections which not only startle us by their abruptness, but occasion us at times no little trouble to account for their presence. This mental phenomenon admits of easy explanation. While the volitions of thought are intensely directed to a particular subject, the associations act in subordination to that which is, for the time, "the ruling idea of the mind;" when this mental intensity subsides, and the attention ceases to concentrate the faculties of thought, the mind relapses into that desultory state which is its ordinary mood in the absence of excitement. Hence the attention which fixes the thoughts controls the associations; the relaxation of attention which allows the thoughts to wander, grants the same license to the associations. A striking illustration of this fact is to be found in what are called reveries—a state of mental ennui, in which the mind shrinks from exertion, and resigns itself to the guidance of the associations. In sleep, this emancipation from mental direction is still more complete; in consequence of which, the order and perspicuity of thought, so conspicuous while attention presides over intellectual exertion, are deranged. Strange contradictions and anomalies present themselves, announcing the suspension of that faculty whose office it is to restrain the wild and involuntary action of the associating power.

It should be added, however, that, although our associations roam at large during slumber, and although they may occasionally refuse to come and go at our bidding at other moments, yet they are capable of being controlled and regulated to a very high degree. A habit of attention is the governing power. Attention implies abstraction from desultory thoughts, and the act of mental direction to a particular subject. The influence of this habit keeps the associations under control; the want of it renders our waking thoughts little less incongruous than the dreams of sleep. It is one of the singular properties of association, that it acts upon the moral as strongly as upon the intellectual part of our nature. Not to speak of its influence upon the generous and noble dispositions of the mind, the passions are perverted by an unlicensed association of ideas. Mr. Locke gives an example of this tendency, in reference to the origin of superstitious fear—a weakness less prevalent in the present than in the past generation. He alludes to the vulgar belief in ghosts as spirits of the night. "The ideas of goblins and sprites have really no more to do with darkness than with light; yet let but a foolish maid inculcate these often on the mind of a child, and raise them there together, possibly he shall never be able to separate them again as long as he lives; but darkness shall ever afterwards bring with it those frightful ideas, and they shall be so joined that he can no more bear the one than the other.'

To avoid this and other errors to which the mind is exposed by an undisciplined use of the associating faculty, the greatest pains ought to be taken to render it not only subordinate but obedient to reason; to place it under the guard of attention, and to fill the intellectual storehouse with such ideas as shall only awaken pure and pleasing associations.

In relation to the phenomena of associations, it is worthy of remark, that we are indebted to modern philosophy for the development, if not for the discovery, of them all. The original elucidation of the principle is ascribed to Mr. Locke, who, in one of the later editions of his 'Essay on the Human Understanding,' added a new chapter entitled 'Of the Association of Ideas,' in which the laws of this power are noticed and some of its phenomena explained. Soon after, Dr. Hartley, in his 'Observations on Man,' investigated the principle more thoroughly, and carried its application from simple ideas to the actions and affections, tracing all the intellectual and moral phenomena up to this source. Mr. Hume, in one of his 'Essays,' published almost contemporaneously, showed that the three connecting principles of all ideas are the relations of resemblance, contiguity, and causation, to which some subsequent writer appended a fourth—namely, contrast. In the works of these philosophers is comprised all that is known in reference to the doctrine of association, later writers having done little more than expand or illustrate the views of their predecessors.

ASSONANCE, *assonancia*, in Spanish romantic and dramatic and in several species of lyric poetry, is a peculiar correspondence in sound in the termination of verses, less complete than that of rhyme. In rhyme (called in Spanish *consonancia*) the vowel in the last accented syllable and all the subsequent consonants and vowels are required to be the same as in the co-rhyming verse; but in *assonance*, though the vowels of the last accented syllable and in all subsequent syllables are the same, the consonants may and ought to be different. Thus, *bárbaro*, which has the accent on the antepenultima, is an assonant with *cálamo* and *plátano*. *Búscas*, which is accented on the penultima, is an assonant with *cúran* and *súya*. (So, in English, *hardy*, *manly*, and *carry*, would be assonants; in German, *toben*, *hoffte*, *oder*.) Corazón, which is accented on the last syllable, is assonant with amór, españól, flor, voz.

Assonants are not, like rhymes, exhibited in insulated pairs, but are continued through the whole poem, or, in dramatic compositions, through an entire act or day (*jornada*), without any other change than the alternation of blank verse with the assonants. Thus, the first, third, fifth, seventh lines, &c., of the act are blank verse, and the second, fourth, sixth, and eighth lines, &c., are all assonants to each other; unless indeed the blank line and the assonanted line which follows it be considered as constituting one long line, terminating with an *asonante*, as in the Arabian prototype supposed to be discovered by Sarmiento in some of the metrical parts of the Koran.

But for this constant recurrence of the same assonance through a long succession of alternate lines, the ear would probably be little struck with this faint species of rhyme, even when proceeding from the mouth of a Spaniard, in which the vowels are so fully and broadly sounded, without being contracted by the use of double consonants, which, while they add to the brilliancy of Italian versification, appear to render it less susceptible of this delicate species of embellishment, so peculiarly adapted to the use of the drama, for which rhyme is perhaps too prominent and too ostentatious an ornament.

Calderón, and the other classical dramatists of Spain, always use *asonantes*. The *asonante* of the drama is that in which the accent is on the penultima, the verse consisting of eight syllables.

In lyric poetry, rhyme is more frequently adopted; but the *endecha*, a species of elegy, and some other lyric measures, require the assonant. The following extracts from romances contain lines alternately blank and assonanted, as is always the case in romantic and in dramatic poetry. In the first of these examples the accent is on the penultima; in the second, on the last syllable:—

Salió el gallardo Aliatar
Con cien Moriscos gall*a*rd*o*s
En defensa de Motril
Y socorro de su herm*a*n*o*.

A caballo salió el Moro,
Y otro dia desdich*a*d*o*
En negras andas le vuelven
Por donde salió á cab*a*ll*o*.

Maldeciré mi hermosura,
Y tambien mi moced*a*d,
Maldeciré el triste dia
Que con vos quise cas*a*r.

The next is an example of double assonants:—

Aguárdate, dixo el p*a*v*o*
Al cuervo de l*é*j*o*s.
¿Sabes lo que estoi pens*a*nd*o*?
Que eres negro y f*e*o.

Escucha; tambien rep*a*r*o*,
Le gritó mas r*e*ci*o*,
En que eres un paxarr*a*c*o*
De mui mal agü*e*r*o*. *Yriarte.*

ASSUMPSIT is the technical term denoting one of those specific forms of action which were provided, at a very early period of the history of English law, as the course by which redress for particular injuries must be pursued. It was so called from the past tense of the Latin word *assumo*, barbarously applied to signify 'I undertake;' being taken from the use of this word, describing the defendant's undertaking, in the old Latin pleadings. The form was "that in consideration that the plaintiff had furnished goods to the defendant, the latter undertook, or rather took upon himself (*super se assumpsit*) to pay the former so much money." The action of *indebitatus assumpsit* was used for the recovery of damages occasioned by the breach of a simple contract; being preferred to the more proper action of *debt*, for technical reasons, which have long ceased to operate. *Assumpsit* is maintainable where there has been an express promise to pay money (as in the case of a promissory note), or to do any other act; or in circumstances from which the law implies a contract. An example of the latter occurs in the familiar instance of the delivery of goods by a tradesman to a customer; in which case, though no express promise to that effect has been made, it is an inference of law that the customer has promised to pay for them as much as they are worth; and, accordingly, the plaintiff's declaration, or formal relation of his cause of action, would state the debt generally, and also an *actual* promise to pay it. This would be called an *assumpsit* on a *quantum valebant*. If the consideration were the personal services of the plaintiff, given for the benefit of the employer, the latter is supposed to promise to pay as much as the plaintiff 'reasonably deserved to have;' and then the action is called an *assumpsit* upon a *quantum meruit*. So also the character and relative situations of parties will often raise a legal liability, from which an *assumpsit* or undertaking will be implied in the absence of any express contract. Thus, an innkeeper is bound to secure the goods of his guests; the law consequently supposes him to promise to do so; and therefore if the goods are lost or injured, he is liable to an action of *assumpsit* for the damage which the owner has sustained. In like manner, it is the duty of surgeons and attorneys to use proper care and skill in the service of those who employ them, and being supposed to promise to do so, they are liable to be called upon in an action of *assumpsit* to make compensation in damages for any negligence or want of skill.

(Blackst.' Comm.' Mr. Kerr's ed. viii. pp. 165—173, and 368.)

ASSURANCE. Of late years it has become usual with writers on life contingencies to speak of *assurances* upon lives, instead of *insurances*, reserving the latter term for contingencies not depending on life, as against fire, losses at sea, &c. [INSURANCE, ANNUITIES, &c.]

ASSYRIAN ARCHITECTURE. The architecture of Assyria, including that of Babylon, will be treated of under NINEVEH, ARCHITECTURE OF.

ASTARTE, Achtoret or Ashtaroth, sometimes called Syria Dea, the Syrian Goddess, one of the deities of Phœnicia, of whose attributes and character we are unable to give a detailed account from the scantiness of the information transmitted respecting her; but who is generally regarded as corresponding with the APHRODITE of the Greeks. The author of the treatise 'De Deâ Syriâ,' usually ascribed to Lucian, says, that Astarte is the same as the Greek Selene (moon); but Cicero ('Nat. Deor.' iii. 23) considers her as the fourth Venus, the wife of Adonis; and if so Lucian says she had temples at Byblis and Lebanus, but he distinguishes her from Astarte. The Romans introduced her as Astarte, making her sometimes the same as Juno, and at others as Diana or Venus. A Roman altar was discovered in 1749, at Corbridge in Northumberland, with a Greek inscription, stating that it was dedicated by Pulcher to Astarte; two engravings of it were given in the 'Archæologia,' vol. ii. pl. 4, vol. iii. pl. 17. Herodian (v. 15) tells us that the Africans call her Urania, which, however, is a Greek name, and the Phœnicians, Astroarche (queen of stars). By others she is thought to be the Here (Juno) of the Greeks, but we think the opinion of Cicero is most consistent with the few facts we know respecting her, and that she was nothing else than the planet Venus, whom the Phœnicians worshipped as Astarte. She is frequently mentioned in the Holy Scriptures in connection with Baal, as seducing the Israelites from their duty. (Judges, ii. 13; 1 Sam. vii. 3, 4, xii. 10 where she is called Ashtaroth in the authorised translation.) Astarte had a magnificent temple at Sidon, where she seems to have been the principal divinity. Solomon is said (1 Kings, xi. 5) to have "gone after Ashtoreth, the goddess of the Zidonians." In Judges, iii. 7, Israel is said to have "served Baalim and the groves," and Ashtaroth is supposed to have been the idol of the groves. Jahn says that whenever the worship of, or in, groves is mentioned in the Old Testament, the moon or Ashtaroth is meant, and hence the order to cut down the groves in Exod. xxxiv. 13, and Deut. vii. 8. Some mythologists speak of Hierapolis in Syria as the central point of her worship, but they have confounded her with Derceto, who was the Dagon of the Philistines. The island of Cyprus received her religious rites from Phœnicia, and this divinity became known there as Aphrodite. The rose and the lotus were sacred to her, and, among animals, the lion, the horse, the boar, the lobster, and the pigeon. The temple of Venus at Ascalon, mentioned by Herodotus (I. 105), was, there can be little doubt, a temple of Ashtaroth; in 1 Sam. xxxi. 10, Saul's armour is stated to have been placed by the Philistines in the house of Ashtaroth.

(Selden, *De Diis Syriis*, 244; Höck, *Creta*, Göttingen, 1823; Münter, *Der Tempel der Himmlischen Göttinn zu Paphos*, Kopenhag, 1824.)

ASTERISM, *a collection of stars*, formerly used for *constellation*, but now appropriated to signify any small cluster, which it is either desirable to distinguish from the rest of the constellation in which it lies, or which is not a part of any particular constellation.

ASTEROIDS. This term is usually applied to the group of small planets revolving between Mars and Jupiter, which have been discovered during the course of the present century, and more especially within the last few years. Any person who attentively considers the relative magnitudes of the orbits of the older planets, will have no difficulty in perceiving that there exists a comparatively wider gap between the orbits of Mars and Jupiter than in the case of any other two consecutive planets. Kepler, who did not fail to remark this anomalous fact, found that it offered an insurmountable obstacle to the success of his researches, while engaged, during the early period of his career, in attempting to connect together the mean distances of the planets from the sun by some general law. He finally hazarded the bold conjecture that a planet really existed between the orbits of Mars and Jupiter, and that the circumstance of its not being visible was due to its extreme smallness. This idea of Kepler's was supported by many eminent German philosophers and astronomers of the last century, including Kant and Lambert, and it acquired an accession of plausibility from the discovery of an empiric formula, usually known as Bode's law of the planetary distances, but which is, in reality, due not to Bode, but to Titius of Würtemberg. Supposing the mean distance of the earth from the sun to be represented by unity, this formula leads to the following numerical results with respect to the mean distances of the planets from the same body. We exclude from this list the planets Uranus and Neptune, which had not been discovered at the time to which our remarks refer.

Name of Planet.			Mean Distance from the Sun.
Mercury	4 + 0	=	4
Venus	4 + 3	=	7
The Earth	4 + 6	=	10
Mars	4 + 12	=	16
Hypothetic planet	4 + 24	=	28
Jupiter	4 + 48	=	52
Saturn	4 + 96	=	100

The law of these numbers is obvious. Now, if we express in terms of the same unit the real mean distances of the planets which were known to exist, we obtain the following results:

Name of Planet.	Mean Distance from the Sun.
Mercury	3·87
Venus	7·23
The Earth	10·00
Mars	15·23
* * * * * *	* * *
Jupiter	52·03
Saturn	95·39

A comparison of the two foregoing tables serves to exhibit the close agreement which presented itself between the actual and hypothetical distances of the planets. It also plainly indicates the necessity which existed for the discovery of an additional planet between Mars and Jupiter, in order that the system of planetary distances should acquire the character of a complete expression of Bode's law.

The discovery of Uranus in 1781, served still further to increase the probability of the existence of such a planet. According to Bode's law the mean distance (see the first of the two foregoing tables) of the next planet beyond Saturn would be $4 + 192 = 196$. The real distance was found to be 191·83.

At length the period arrived which was to be signalised by the discovery of the long suspected planet. On the night of January 1, 1801, Piazzi, the celebrated Italian astronomer, in the course of his labours at the Palermo Observatory, determined the position of a small star in the constellation Taurus, which he found, a few days afterwards, to have a retrograde motion in the zodiac. His impression was that the moveable body was in reality a comet, although it exhibited none of the usual features of such bodies, and for some time after its discovery he refrained from communicating to astronomers its apparent position, in all probability with the view of being himself enabled in the first instance to deduce from them the elements of its orbit. He continued to observe the strange body from night to night down to the 11th of February, when his further labours were interrupted by an illness. In the meantime he had transmitted to Oriani, Bode, and Lalande, some results of his observations, but before they reached either of those astronomers it was found that the moveable body had approached too near the sun to admit of obtaining any further determinations of its position. It plainly appeared, however, from a discussion of Piazzi's observations, that the object discovered was in reality a planet revolving in the region between Mars and Jupiter, in accordance with Bode's law. Gauss, who had just entered on his brilliant career as a theoretical astronomer, having obtained possession of Piazzi's observations, determined the elliptic elements of the planet's orbit by a method of his own invention, and calculated an ephemeris of its motion, for the purpose of aiding in its re-discovery. In the month of September the planet, according to Gauss's calculations, had sufficiently emerged from the rays of the sun to hold out a hope of its detection; and an active search for it was forthwith instituted at various observatories throughout Europe. This was a much more troublesome operation than a similar search would be in the present day, when so many excellent charts are available to the observer. On the 7th of December, von Zach, who then held the appointment of Director of the Observatory at Seeberg, obtained a trace of the planet, but a continuance of cloudy weather prevented him from verifying his observation until the 31st of the same month, when he obtained a complete assurance of his re-discovery of the body. Olbers, the celebrated astronomer also re-discovered it, independently, on the following evening at Bremen. Piazzi, the discoverer upon whom devolved the right of naming the planet, bestowed on it the appellation of Ceres Ferdinandea, but the latter epithet, proposed by him as a compliment to his sovereign and patron, speedily fell into disuse, and the appropriate name of Ceres, in allusion to the titular deity of Sicily, was alone retained.

Pallas, the second of the group of minor planets, was discovered by Olbers, on the 28th of March, 1802. Its orbit was calculated by Gauss, who found its mean distance from the sun to be 2·670, agreeing very nearly with the mean distance of Ceres. The inclination of its orbit to the ecliptic was, however, still greater than in the cases of the last-mentioned planet, amounting to so much as 34° 49′. It was also remarkable for the great eccentricity of its orbit, which was equal to 0·24764, exceeding in this respect any of the planets hitherto discovered.

From the circumstance of two planets of very small magnitude having been discovered with nearly equal mean distances from the sun, and with inclinations greatly exceeding those of the older planets, Olbers was led to entertain the curious notion that the two bodies might be in reality fragments of some larger planet which had suffered an explosion from some internal convulsion, and he suggested that many more of such fragments might be found revolving in the same region. He remarked further that, if this hypothesis were true, the orbits of the various fragments might obviously have very different inclinations with respect to each other and to the ecliptic, but that they would all have two common points of intersection in opposite regions of the heavens. These two points were found, in the case of the two newly-discovered planets, to be situate in the constellations of Virgo and the Whale. He accordingly proposed, with a view to the discovery of further fragments of the planet, that a careful examination should be undertaken, and henceforward uninterruptedly maintained, of the regions in those two constellations which included the common points of intersection of the orbits of the two bodies. In the meantime, his views received additional support from the discovery of a third planet, Juno, by Harding, at Lilienthal, on the 2nd of September, 1804. The new planet was discovered in the constellation Pisces, near the region in the Whale through which Olbers had maintained that the fragments of the shattered planet would necessarily pass.

Olbers continued with unwearied perseverance to explore the two opposite regions of the heavens in which he expected to discover further fragments of his supposed shattered planet. At length, on the 28th of March, 1807, his efforts were rewarded by the discovery of another planet, Vesta, in the north wing of the constellation Virgo, one of the regions of the heavens in which he expected to effect such a discovery. The mean distance, as determined by the calculations of Gauss, plainly indicated that it belonged to the group of new planets between Mars and Jupiter. In accordance with his hypothesis, Olbers continued for several years after his discovery of Vesta to search for further fragments of the shattered planet, confining his attention to the two opposite regions through which he expected that they would in each instance necessarily pass in the course of their revolution around the sun, but no new triumph rewarded his labours. Subsequent discoveries have not served to confirm the somewhat fanciful idea upon which his system of observation was founded.

The new planets were found to be excessively small, exhibiting hardly an appreciable apparent magnitude even when viewed in the most powerful telescopes. Sir William Herschel having measured the apparent diameter of Ceres under favourable circumstances, found that at the mean distance of the sun from the earth it would subtend an angle of $0''\cdot35$, whence it was easy to infer that the absolute diameter of the planet amounted to 161 miles. In a similar way he found that the absolute diameter of Pallas was not more than 110 miles.

In consequence of the strong resemblance which the new planets bore to each other, both in size and in the forms and positions of their orbits, and the contrast which they offered in these respects to the older planets, Herschel proposed that they should be called *Asteroids* rather than planets. This mode of designation was favourably received, and is now generally applied to those bodies.

With the exception of Olbers himself, it does not appear that any contemporary astronomer was induced to undertake a systematic exploration of the heavens in search of new asteroids. The want of good star-charts rendered all operations of this kind exceedingly laborious during the early period of the present century. In the year 1825, however, a circumstance occurred which was destined to exercise an important influence on the progress of such researches. This consisted in a proposal on the part of the Berlin Academy to construct a series of star-charts, on which should be laid down all the stars to the ninth magnitude inclusive, comprised in the region of the heavens which extends to a distance of 15° on each side of the equator. It was arranged that the zone in question should be divided into twenty-four parts, corresponding to the twenty-four hours of right ascension; and astronomers of all countries were invited to unite in carrying this project into effect, each co-operating astronomer undertaking the execution of one hour of right ascension. The views of the Berlin Academy met with a favourable response from astronomers, and although only a short time has elapsed since they were carried into complete effect by the construction of the last of the twenty-four charts constituting the zone, still the publication of the individual charts from time to time was productive of important results.

The utility of star-maps in searching for new planets is obvious enough. The observer compares his map with the corresponding region of the heavens. If a star should appear in the heavens which is not inserted in the map it may be presumed to be a planet which has wandered into the region of the map since the epoch of its construction. On the other hand if one of the stars in the map should be missing in the heavens, it may be reasonably supposed that the object is in reality a planet which was laid down as a fixed star at the time of the construction of the map, and has subsequently travelled entirely out of the region to which the map corresponds. The observer, aided by this clue, then proceeds to explore the heavens in the immediate vicinity of the region of the map with the hope of discovering the missing object.

It is plain from the foregoing remarks that trustworthy star-charts are indispensable in searching for new planets. The Berlin charts were obviously very valuable for this purpose, since they included stars of a magnitude considerably inferior to that exhibited by the newly discovered asteroids. It was probably from a consideration of the advantages offered by these charts in the exploration of the heavens, that M. Hencke, an amateur astronomer, residing at Driesen in Germany, was induced in the year 1830, to undertake a search for further asteroids. After devoting fifteen years to a persevering scrutiny of the heavens his labours were finally rewarded by the discovery of a fifth asteroid, Astræa, on the 8th of December, 1845; and two years afterwards, on the 1st of July, 1847, by the discovery of a sixth asteroid, Hebe.

Henceforward the progress of discovery has continued without interruption down to the present time. The aggregate number of asteroids ascertained to exist at the time when this sheet is passing through the press (1859, March 15), amounts to fifty-six. It is usual to characterise each asteroid by the number, enclosed in a circle, indicative of its rank in the order of discovery. The following is a complete list of the various discoveries.

Planet.	Date of Discovery.	Name of Discoverer.	Place of Discovery.
1 Ceres	1801, January 1	Piazzi	Palermo
2 Pallas	1802, March 28	Olbers	Bremen
3 Juno	1804, September 1	Harding	Lilienthal
4 Vesta	1807, March 29	Olbers	Bremen
5 Astræa	1845, December 8	Hencke	Driesen
6 Hebe	1847, July 1	Hencke	Driesen
7 Iris	1847, August 13	Hind	London
8 Flora	1847, October 18	Hind	London
9 Metis	1848, April 25	Graham	Markree
10 Hygeia	1849, April 12	De Gasparis	Naples

52 Europa	1858, February 6	Goldschmidt	Paris
53 Calypso	1858, April 4	Luther	Bilk
54 Alexandra	1858, September 10	Goldschmidt	Paris
55 Pandora	1858, September 10	Searle	Albany, U.S.
56 * * *	1857, September 9	Goldschmidt	Paris

In the foregoing list the number prefixed to each asteroid indicates the order of discovery. With respect to the fifty-sixth asteroid (which has not yet been named), there appears to be a deviation from this rule, for according to the date of discovery assigned to it in the second column it ought to rank as the forty-seventh in the list. The origin of this apparent inconsistency is interesting. Upon the discovery of

* Discovered independently, although subsequently in respect of time, by M. de Gasparis.

† Discovered independently by M. Chacornac.

‡ Discovered independently by Mr. Pogson, and also by M. Chacornac.

§ Discovered independently by M. Luther.

Daphne, it was found to have already considerably passed opposition (when it is nearest the earth), and that only a few observations of it could be obtained before it was lost in the sun's rays. From the positions thus determined, the elements of the planet's orbit were calculated by M. Pape of Altona, but in consequence of the small extent of the arc on which they rested, it was feared that considerable difficulty would be experienced in rediscovering the planet upon coming to opposition in the following year. However, guided by an ephemeris founded on M. Pape's elements, M. Goldschmidt discovered an asteroid on the 9th of September, 1857, which he supposed to be Daphne, and under the impression that his surmise was correct, a considerable number of positions of the asteroid were obtained at various observatories throughout Europe. It is only within the last few months that M. Ernest Schubert, a German astronomer, has found that the orbit calculated from the observations of 1857 is totally irreconcilable with the positions of Daphne obtained in the previous year. It was plain, therefore, that the observations of 1856 and 1857, referred to two distinct bodies, and that the object discovered by M. Goldschmidt on the 9th of September, 1857, was in reality not Daphne, but a new asteroid. Since the date just mentioned, however, nine additional asteroids had been discovered, to each of which the proper characteristic number had been prefixed. In order, therefore, not to disturb this arrangement, astronomers have agreed to distinguish the asteroid originally observed on the 9th of September, 1857, by the numerical symbol (56). In the mean time, the asteroid Daphne has not been seen since 1856, the year of its discovery.

The ten asteroids attributed to Mr. Hind in the foregoing list, and also the asteroid discovered by M. Marth, were discovered at the observatory of Mr. Bishop, Regent's Park, a gentleman who, by the munificent patronage which he has extended towards astronomy during a long series of years, has earned for himself an honourable name in the annals of science. It is worthy of remark, that M. Goldschmidt, the discoverer of twelve asteroids, is by profession an historical painter. His discoveries have been all made during his leisure hours in the evening, with a telescope of comparatively moderate dimensions fitted up in an apartment of his private residence.

Allusion has been made to the useful services rendered by the Berlin charts in the discovery of asteroids. Recently they have been superseded in so far as this object is concerned by charts of a more limited range, but which include stars of a smaller magnitude. The construction of such charts has been rendered necessary by the faint aspect of the asteroids discovered in recent years (being generally inferior in brightness to stars of the tenth magnitude). It is of course reasonable to suppose that the brighter asteroids would have been detected in the first instance. Charts for the discovery of further asteroids are in the course of being published at the expense of Mr. Bishop. Similar] charts, constructed by M. Chacornac are also emanating from the Imperial Observatory, Paris.

The theory of the movements of the asteroids is almost entirely due to the German astronomers, more especially Gauss, Encke, and Hansen. Upon the discovery of one of those bodies, the first step is to determine the elements of the orbit from a limited number of observations. For this purpose the method given by Gauss in his immortal work, the 'Theoria Motus,' or a modification of it by Encke ('Berlin Jahrbuch,' 1854), is usually employed. The results thus obtained are subsequently corrected by a discussion of all the observations made during the opposition of the asteroid (on which occasion alone it is generally visible), taking into account the effects of perturbation, more especially those due to Jupiter the principal disturbing body. In consequence of the great magnitude of the eccentricities and inclinations of their orbits, the methods usually employed in computing the perturbations of the older planets, are not generally applicable to the asteroids.* It has accordingly been found necessary to have recourse to what has been called the method of quadratures. In other words, instead of computing the perturbations from general formulæ, involving mean values of the elements as determined by the discussion of a long series of observations, the astronomer calculates their numerical effects for a succession of special epochs, by a process not adapted to mean elements (and therefore not admitting of direct application to any time whether past, present, or future), but to osculating elements corresponding to some given epoch. These elements, being used as the starting point of calculation, are subsequently corrected at the close of each of the intervals into which the period of perturbation is divided.

In more recent times MM. Hansen and Encke have devised methods for obtaining general formulæ of perturbation which are applicable to all the asteroids. Tables of Flora founded on formulæ derived from the development of Professor Encke's method, have been calculated by Dr. Brunnow. Professor Hansen has applied his theory to the asteroid Egeria.

The following synopsis [see cols. 644, 645, and 646] of the elements of all the asteroids hitherto discovered has been derived from the Berlin 'Jahrbuch' for 1861, with the exception of the elements of the fifty-sixth asteroid, which have been taken from No. 1175 of the 'Astronomische Nachrichten.' The longitudes, except in the last instance, are invariably referred to the mean equinoxes of their respective epochs. In the case of the fifty-sixth asteroid, the equinox of reference is that of 1857·O.

It may be remarked that the researches on the perturbations of the asteroids have led to an important correction of the value of Jupiter's mass. Nicolai of Mannheim (Berlin 'Jahrbuch,' 1826) was first led to conclude by a discussion of fifteen oppositions of Juno, that theory was incapable of representing the results of observation, unless the value of Jupiter's mass was increased by about $\frac{1}{80}$th. The generally admitted value of this important element of physical astronomy ($\frac{1}{1070}$) rested on Pound's measures of the elongations of Jupiter's satellites,

* In the case of Vesta, tables have been calculated by Santini and Daussy from general formulæ representing the effects of perturbation. In the 'Connaissance de Temps' for 1846, Damoiseau has given the general formulæ for the perturbations of Juno and Ceres.

which had not been verified by any subsequent astronomer, although the result was supported by Bouvard, who obtained nearly the same value by an application of Laplace's formulæ for the perturbations of Saturn by Jupiter. On the other hand, the researches of Encke on Vesta, and those of Gauss on Pallas, seemed to indicate that some such alteration as that suggested by Nicolai was necessary. The doubt was cleared up by Mr. Airy, who, upon remeasuring the elongations of Jupiter's satellites, found that the observations of Pound were considerably erroneous. The value of Jupiter's mass thus corrected ($\frac{1}{1048}$) has been found to satisfy the results of observation in so far as the perturbations of the asteroids are concerned, although the theory of Saturn would appear still to leave some room for doubt.

The asteroids must be bodies of very inconsiderable magnitude, for notwithstanding their comparative proximity to the earth, they only in a few instances exceed in brightness stars of the eighth magnitude, even when observed at the times of opposition; while, generally speaking, they fall very far below this standard. The following table expresses the brightness of the various asteroids which come to opposition in the year 1859. The numbers in the third column correspond to the time of opposition as given in the second column.

Name of Asteroid.	Inclination to the Ecliptic.	Longitude of the Ascending Node.	Mean Longitude.	Epoch in Berlin Mean Time.	Name of Calculator.

The asteroids, Iris, Hygeia, Egeria, Thetis, Phocea, Urania, Pomona, Leucothea, Lætitia, Ariadne, Nysa, Aglaja, Doris, and Pandora do not come to opposition in 1859. The asteroid (56) which is not included in the list from which the foregoing numbers are extracted, may be stated to be about the 10·11th magnitude when it comes to opposition.

Since the asteroids exhibit no appreciable discs by the measurement of which their absolute diameters might be determined, as in the case of the other planets, astronomers have endeavoured to accomplish the same object by means of photometric results, founded on their apparent brightness, combined with an assumption relative to their power of reflecting the solar light. Professor Stampfer, of Vienna, has endeavoured in this way to determine the absolute magnitudes of several of the asteroids. By photometric experiments he found that the planets Mercury, Venus, and Jupiter, possess the same capacity for reflecting the solar light. By extending this principle to the asteroids, the following results have been obtained (Bruhns, 'De Planetis Minoribus,' Berlin, 1856) relative to the absolute magnitude of those bodies.

Asteroid.	Diameter in Miles.	Asteroid.	Diameter in Miles.

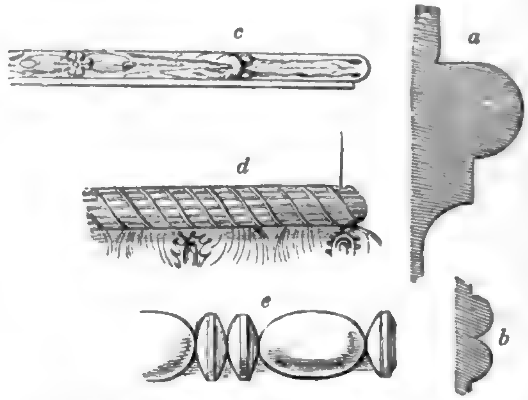
No trustworthy conclusion can be arrived at respecting the aggregate number of the asteroids. If, indeed, we suppose them to be all of the average size of those already discovered, we might then be enabled to form some opinion on the subject, for the zone in which they perform their revolutions contains only a definite number of stars of the average apparent magnitude of those bodies. But the more the search for new asteroids is prosecuted and the greater their aggregate number becomes, the smaller the more recently-discovered ones turn out to be, and the obvious inference therefore is, that there probably exist many more of such bodies, which from their minute magnitude have hitherto escaped detection.

But if it is impossible to assign any limit to the number of the asteroids, the result is different when we consider their aggregate mass. In this case it may be ascertained by calculations founded on the theory of gravitation, that if the quantity of matter contained in the totality of those bodies exceeded a certain amount, their attractive force could not fail to produce sensible perturbations in the movements of the neighbouring planets Mars and the earth. M. le Verrier has considered the subject from this point of view. His researches are founded on the twenty-six asteroids which had been hitherto discovered, but the conclusion at which he arrived is equally applicable in the present day. He found that if the aggregate mass of the asteroids was equal to the earth's mass, its attraction would disturb the place of the perihelion of Mars to the extent of 11″ in a century. Now, if there really existed from such a cause a variation in the perihelion of the planet, amounting to even the fourth part of this quantity, it could not escape observation in the present advanced state of practical astronomy. The conclusion therefore is that the aggregate mass of the asteroids does not amount to one-fourth of the earth's mass.

ASTHMA. [BRONCHITIS.]

ASTRAGAL, a moulding used in architecture, and applied principally to the upper ends of the shafts of columns and to their bases. It is also used in the entablatures of the Roman Doric, the Ionic, Corinthian, and Composite orders. The term is derived from the Greek ἀστράγαλος, which signifies the bone on which the tibia rests, and sometimes a vertebra. The form of this moulding is semicircular, projecting from a vertical diameter. The surface is usually worked plain, although there are Roman examples of its being carved to represent leaves, as in the arch of the goldsmiths at Rome, or reeds bound together, as in the pedestal of Trajan's column. The astragal cut into beads is common to Greek and Roman architecture.



Sections of astragal mouldings, and elevations of astragal mouldings carved:—*a*, section of an astragal form the three columns of the temple of Jupiter [Stator], in the Campo Vaccino, at Rome; *b*, astragal used in the base of the Ionic order of the temple of Minerva Polias at Priene; *c*, enriched astragal used in the arch of the goldsmiths at Rome; *d*, enriched astragal of the pedestal of Trajan's column at Rome; *e*, astragal cut into beads.

The apparent use of the astragal is, to bind the parts of columns and entablatures together, for which purpose it is employed both at the top of the shaft where the capital commences, and at the bottom where the base terminates. Many of the parts also of the entablature are bound together with the astragal moulding.

In Egyptian architecture, bands curved after the manner of astragals seem to bind the reeds of which the shaft of the column often appears to be formed. In the choragic monument of Lysicrates at Athens, supposed to be one of the oldest examples of the Corinthian order, it has been conjectured that the hollow between the top of the shaft and the lower part of the capital of the column formerly received a bronze ring of the form of an astragal, by which means, if the conjecture be well founded, the parts, from the contrast of colour, would appear to be more *distinctly bound together*. The most remarkable example of the use of the astragal in Grecian architecture is in the base employed in the Ionic temple of Minerva Polias at Priene; which has been imitated by Mr. Cockerell in the portico in the front of Hanover Chapel, Regent-street. In the temple of Jupiter Olympius, at Athens, the astragal at the top of the column appears to have a channel cut underneath it. (Stuart, vol. iii.) This, however, is very unusual. [COLUMN.]

ASTREA, one of the group of small planets revolving between Mars and Jupiter. [ASTEROIDS.]

ASTRINGENTS (from *astringo*, to constringo, or bring closer together) are agents which contract the fibres of the muscles and blood-vessels, and lessen the flow of fluids, whether it be the secretions of the glands proceeding from their natural orifices in excessive quantity, or the contents of the blood-vessels escaping by their exhalent extremities, or by an unnatural opening (or rupture). They produce this effect, generally by a vital, but sometimes by a chemical action. Their power is manifested first, and often solely, on the part to which they are applied; yet in many instances it is extended by sympathy very rapidly over the whole body, as is observed when the acerb juice of the aloe is brought in contact with the tongue. The sensation then experienced may be considered the best general test of the presence of *astringency*, which cannot be ascribed to any one principle, but is owing to tannin, gallic acid, and hæmatine, in vegetable astringents, and is possessed by acids, and many metallic salts among mineral agents; and is also one of the effects of the application of cold to the body. In vegetables, the astringent principles are found chiefly in the bark (as oak), the root (as rhatany and tormentil), and the wood (as logwood). As wood and bark form parts of *exogenous* trees only, it is only from this section of the vegetable kingdom that any astringent principles can be obtained. [See explanation of the term *exogenous*, under the article AGE OF TREES.] Sir Humphry Davy found that the inner layer of the bark possessed the greatest quantity of the astringent principle: this is the natural consequence of the mode in which the sap descends from the leaves, namely, through this inner layer of bark, whence it occasionally passes into the wood, which will then be found to possess principles similar to those of the bark. Most astringent vegetables are red, owing to the presence of an acid in excess, which is often manifest to the taste, as in rumex or sorrel. In metallic astringents, when super-salts, the excess of acid is also very perceptible to the taste, as in alum, which is a supersulphate of alumina and potassa.

The particular principle to which any substance is indebted for its astringent power, may be ascertained by appropriate tests. When *tannin* exists in plants, its presence may be proved by an insoluble precipitate taking place on the addition of a concentrated solution of gelatin. The precipitate is a compound in definite proportions of tannin and gelatin, being forty-six of tannin and fifty-four of gelatin. Gelatin has therefore been proposed by Sir Humphry Davy as a test of the quantity of tannin in different astringent vegetables. (See 'Philosophical Transactions,' 1803.) But in the practical application of this test there are some sources of fallacy difficult to guard against. (See Papers by Dr. Bostock in Nicholson's 'Journal,' vol. xxiv. 1809, and by Mr. E. B. Stephens, in 'Annals of Philosophy,' New Series, vol. x. p. 401.) Tannin rarely exists alone, though it probably does so in catechu, but mostly along with gallic acid. Extractive is also a frequent accompaniment of tannin, and is of considerable service, assisting its action in the process of tanning. Gallic acid strikes a bluish-black precipitate with all the salts of iron, but a solution of the persulphate is the ordinary test. Hæmatine exists in logwood, along with tannin and extractive. It may be known by combining with oxide of lead without undergoing any change.

The effect of astringents which is due to their chemical action is nearly the same in dead as in living animal matter; their long-continued application to the skin will produce a condition similar to that of a tanned hide. They are therefore sometimes employed to effect this, when internal parts are exposed, to change them from a secreting to a non-secreting surface—such as in irreducible prolapsed uterus. Their use in this way however is very limited, whilst their vital action is extensive and important. The chief effects of astringents are to contract the muscular and vascular tissues, to diminish secretion, and lessen irritability, and in many instances to impart strength or increased tone to an organ or part. Their action is always greatest on the part to which they are applied. When a drop of diluted acetic or sulphuric acid is applied to the skin, whiteness of the part is observed, which soon disappears, and the natural colour, or even a more intensely red one, follows. If this is frequently repeated, the structure of the part is changed; it ceases to secrete, is no longer pliant, but becomes stiff and inflexible. The loss of colour is owing to the diminished calibre of the blood-vessels, which no longer admit the red globules. During the absence of these, the sensibility of the part is less than natural; just as cold and torpid fingers lose their fineness of touch. Nearly similar effects may be supposed to follow the internal administration of astringents, the action of which is greatest on the intestinal canal, and less on parts remote from this; yet it deserves to be remarked, that as the intestinal canal is a mucous membrane, and possesses a muscular structure, parts of a similar structure are more influenced by astringents introduced into the stomach than other parts are: hence, increased secretion from the mucous membrane of the lungs, or from the lining membrane of the bladder, or flow of blood from arteries, is more effectually checked by astringents than increased exhalation from serous surfaces. There is reason to believe that the astringent principle of many plants does not enter into the circulation, but passes along the whole course of the intestinal canal without being absorbed; for Sir Humphry Davy found, that when tannin is present in grasses, as it is in that of *aftermath crops*, it is voided in the dung of the animals which feed upon it. (See Davy, 'Elements of Agricultural Chemistry, Appendix,' p. lxi.) But that of other plants enters the system so rapidly, that the astringency of the *Uva Ursi*, or bear's whortleberry, can be detected in the urine forty-five minutes after it has been swallowed. In the case of those which do not enter into the circulation, any beneficial effect which they exert upon remote organs must be attributed to that sympathy which exists in so great and unquestionable a degree between the stomach and almost every organ of the body. That such vegetable substances, while passing along the intestinal canal, promote the fulfilment of its functions, is obvious, from the effects following the use of food in which astringent principles are absent. Plants possessing astringent powers and bitter principles, such as tormentil and the bog-bean, are very efficacious in preventing the rot in sheep (as has been already stated under ANTHELMINTICS), while watery grasses, among which no astringent plants grow, favour the generation of worms.

The primary sympathetic effect of several of the astringents which ultimately enter into the circulation, is the most valuable in some of the cases in which they are employed, such as dilute sulphuric acid, which often checks hæmorrhage by closing a bleeding vessel, before any of it can be conceived to have been conveyed directly to the bleeding orifice; it checks the flow of blood in the same way as cold suddenly applied to the surface or skin does. The tonic effect of many astringents, after their use for some time, first on the digestive organs, and afterwards upon the whole system, and more especially upon any weak organ, must be admitted, and borne in mind in forming our estimate of their utility in a curative point of view. Without attempting to account for the ultimate cause of the action of astringents, to do which successfully seems impracticable in the present imperfect state of our knowledge, it may be stated, that under their influence a tension of the parts is produced, during which the muscular and vascular structures acquire an increase of power, and secreting surfaces and glands produce less fluid, but more natural secretions. Some indeed lessen the action of the heart, and so stop the flow of blood from dilated or ruptured vessels, such as the preparations of lead, which, though in some degree astringent, ought to be considered at *sedatives*; while others which combine with, and neutralise the unhealthy or excessive secretions, as lime and its carbonate with the secreted fluids of the intestinal canal, are more properly termed *absorbents* than astringents. When astringents are applied directly to the bleeding vessels, such as to external wounds, or to the nostrils or gums, they are termed *styptics*, and in such cases they often act chemically as well as vitally.

Before proceeding to consider the cases in which astringents may be advantageously used, an enumeration of the most common and valuable substances may be given. Of vegetable astringents the chief are *barks*, as of oak and willow, the best kind of the former of which is obtained from the *Quercus robur* of Linnæus (the true British oak) which is synonymous with the *Quercus pedunculata* of Willdenow, while the inferior sort is obtained from the *Quercus sessiflora* of Salisb., which is synonymous with the *Quercus robur* of Willdenow. The best willow-bark is procured from the *Salix pentandra*, or sweet bay-leaved willow, though very excellent bark is yielded by the *Salix Russelliana*, or Bedford willow. Roots, as of tormentil (*Potentilla tormentilla*); bistort (*Polygonum bistorta*); common avens (*Geum urbanum*), which are British plants; and rhatany (*Krameria triandra*), rhubarb (*Rheum palmatum*); pomegranate (*Punica granatum*), which are exotic plants; leaves of arctostaphylos (*Uva ursi*), petals of the *Rosa gallica*, fruits of *Prunus spinosa*, or sloe-thorn (*Punica granatum*), and secreted juices of many plants, as kino, from *Petrocapus marsupium*, and several others; catechu, from *Acacia catechu*, and galls, from *Quercus infectoria*; in all of which the astringent principle is tannin, with more or less of gallic acid; log-wood (*Hæmatoxylon Campechianum*), in which hæmatine as well as tannin possesses an astringent property; and *Ægle Marmelos*, or Indian Bael. Acetic acid must also be classed among the vegetable astringents.

The mineral astringents are—diluted sulphuric acid, and salts of iron, zinc, copper, silver, and the salts of lead. Cold, in whatever way applied, is also a valuable astringent, particularly in the form of ice.

In treating of the employment of astringents as curative agents, it is necessary to distinguish between their action as local, direct, and often chemical, and their action as general, influencing remote organs, their effects upon which are vital rather than chemical; also between their mere astringent power and their tonic power. The beneficial effects of many of the above-named astringents in checking increased secretion, is doubtless often due to their tonic power; for as in a weak state of the system or any particular gland, the secretions are generally profuse in quantity, a return to the healthy proportion and quality can only be insured by increasing the power or tone of the body or gland, which astringents do by bringing the living tissues into a closer or more compact state, and which tonics do by heightening the vitality of the debilitated structures. Hence astringents are beneficially employed in diseases where a laxity of the muscular and vascular tissues exists, accompanied with imperfect discharge of the functions of the secreting organs. The stomach and intestinal canal being the channel by which is conveyed the material necessary for the nourishment and vigour of the system, and for maintaining a capacity to discharge their functions in the other organs of the body, an impaired state of the structure and functions of this canal extends to every other part. The re-establishment of its healthy condition is a primary object in endeavouring to cure many diseases. Of these intermittent and remittent fevers may be taken as an example, since in these there is always great debility of the digestive organs, and of all the parts which have the most intimate sympathy with them, such as the skin. Astringents possessed of a tonic power have, therefore, mostly been resorted to, in order to remove this debility; cinchona-bark, willow-bark, and many others, have been used with this intention. These, however, are to be avoided whenever any acute inflammation exists, which must first be subdued by appropriate means before tonic astringents can be safely or advantageously used. In diseased states of the intestinal canal, in which greatly increased or unhealthy secretions take place, as diarrhœa, dysentery, and cholera, the most careful inquiry should be made into the cause of the disease, that if it has its origin in an inflammatory condition of the mucous membrane of the intestine, or is owing to the presence of any acrid substance, the former may be overcome by antiphlogistic measures, and the latter be removed by purgatives. When the increased flow from the intestines is connected with increased determination towards these parts, owing to the application of cold to the outer surface suppressing the secretion of the skin, which has the greatest sympathy with the internal surface, and which consequently is excited to double action, a preternatural quantity of secreted fluid is produced. The most effectual, as well as only *safe* means of diminishing this, in the early stages of its occurrence, is the employment of diaphoretics, or such medicines as restore the action of the skin; after which, should the discharge continue, mild astringents may be used, of which logwood or tormentil is the best. A preliminary treatment is likewise required in dysentery: in the common cholera a purgative should generally be given before any astringent is administered.

In the bilious cholera of autumn, after the employment of suitable purgatives, nothing seems to act more effectually as an astringent than the infusion of cusparia, or angustura bark, with dilute nitric acid; to which, in some cases, a small portion of laudanum may be added at first, but afterwards omitted. Nor in the slighter cases of epidemic cholera, has more marked benefit followed the use of any means than has resulted from the employment of this combination, which speedily checks the liquid discharges, and restores the circulation and animal heat.

Diarrhœa, or looseness of bowels, proceeding from acid secretions, is best removed by the astringents which combine chemically with these —such as lime, or its carbonate, which are rendered more suitable by uniting them with aromatics, an excellent form of which is supplied by the *mistura cretæ*, or chalk mixture of the pharmacopœia.

The next most important class of diseases in which astringents may be employed are termed hæmorrhages, or a discharge of blood, either from the exhalant extremities of the arteries, when they are gorged or when they are too much relaxed, or from the wounded or ruptured coats of any blood-vessel. The above distinction refers to the differences between active and passive hæmorrhage, or that which takes place when the system is too full of blood and the vessels propel it with great force; the other, which takes place when the power of the vessel is greatly below the natural standard. In the former, astringents cannot safely be employed at the commencement of the flow of blood, but time should be allowed for the vessels to unload themselves; or a vein should be opened, cooling saline medicines administered, cold air admitted freely to the surface of the body, and, under competent medical attendance, opium or laudanum may be given; after which, astringents will either not be required, or if so, may be safely used.

In passive hæmorrhage they may be employed from the commencement; and perhaps, in most cases, a saturated solution of alum in the infusion of roses is to be preferred, though the tincture of the muriate of iron is very eligible when the kidney is the source of the bloody discharge, as acetate of lead is when the lungs are the organs whence the blood flows. So long as lead is kept in the state of an acetate, its administration is perfectly safe: it should therefore always be accompanied with dilute acetic acid.

Bleeding from the nostrils or gums may be checked by the direct application of styptics; such as preparations of zinc or copper. Nitrate of silver will frequently stop the flow of blood from a leech bite; collodion more effectually still. Cold should, in most cases, be employed along with the other means; even alone it is often successful, especially in the form of water poured from a height in uterine hæmorrhage. Ruspini's styptic, which is said to be a solution of gallic acid in alcohol, is sometimes useful, where other means have failed. Matico is very useful.

The application of astringents to more limited examples of loss of tone or increased flow of secreted fluids, need not be extensively noticed here. After acute inflammation of the eye, proper antiphlogistic means having been used, astringent applications are very serviceable, especially those of zinc and nitrate of silver, either in solution or made into an ointment. Scrofulous inflammation of the eye is often benefited by them, if internal means be also used. Salivation, or excessive flow of saliva, occurring either spontaneously or from the use of mercury or other means, is often effectually checked by nitrate of silver, or decoction of the rhus glabrum, or by iodine, or infusion of cloves. Nitrate of silver, by lessening the inflammation which gives rise to them, also frequently removes morbid discharges from other mucous surfaces besides those we have specially noticed; an effect which also often follows the use of diluted chloride of soda. The colliquative sweats of hectic fever are best checked by giving internally dilute sulphuric acid, and sponging the skin with vinegar and water, or by oxide of zinc.

Astringent substances are decomposed by, or decompose, many others, which therefore should not be given at the same time with them; such, for example, as ipecacuanha with most of the vegetable astringents which contain tannin, by which an insoluble tannate of emetina is formed: when kino is united with calumba, a purgative action follows. All astringent vegetables containing tannin, except oak-bark, decompose tartrite of antimony, and are therefore the best antidotes to it, especially tea.

The ancient Egyptians would appear to have been acquainted with the power of astringents in preserving vegetable as well as animal substances, and they seem to have dipped the coarse cloths in which the mummies were enveloped in some astringent liquid, which tanned the skin, and rendered it less subject to change, as well as excluded the air from the interior of the body. The article employed by them with this view is supposed to have been some sort of kino. The same substance is said to be used by the Chinese to dye cotton for their nankeens, but perhaps a peculiar cotton.

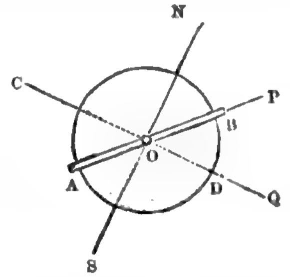
This property of astringents may be usefully applied for the preservation of all kinds of cordage, fishing-lines, and nets, which last much longer if steeped in an infusion of oak-bark. Though inferior in preserving power to the plan of Mr. Kyan, it may be applicable in some cases where his is inadmissible. [ANTISEPTICS.]

For further information on astringents, see Dr. A. T. Thomson's 'Elements of Materia Medica and Therapeutics,' vol. ii., in which much recent valuable matter is brought together.

(For the employment of astringents in the arts, see DYEING AND TANNING; and also 'Library of Entertaining Knowledge'—Vegetable Substances; Materials of Manufactures, p. 178, 1st edition).

ASTROLABE, from two Greek words, signifying *to take the stars*. It has an earlier and a later meaning. As used by Ptolemy, it may stand for any circular instrument used for observations of the stars; but in the 16th and 17th centuries it signified a projection of the sphere upon a plane, being used in the same sense as the word *Planisphere*. To this small projection, which had a graduated rim, sights were added, for the purpose of taking altitudes; and in this state it was the constant companion and badge of office of the astrologer. In later times, before the invention of Hadley's quadrant, a graduated circular rim, with sights attached, called an astrolabe, was used for taking altitudes at sea, as further described in Bion, 'Traité des Instrumens de Mathématique,' Hague, 1723. In the older sense of the word, every one of our modern astronomical instruments is a part of the astrolabe, the principle of which we proceed to describe.

If a solid circle be fixed in any one position, and a tube be fixed upon its centre, round which it may be allowed to move, as in the adjoining diagram; and if the line C D be drawn upon the circle, pointing towards

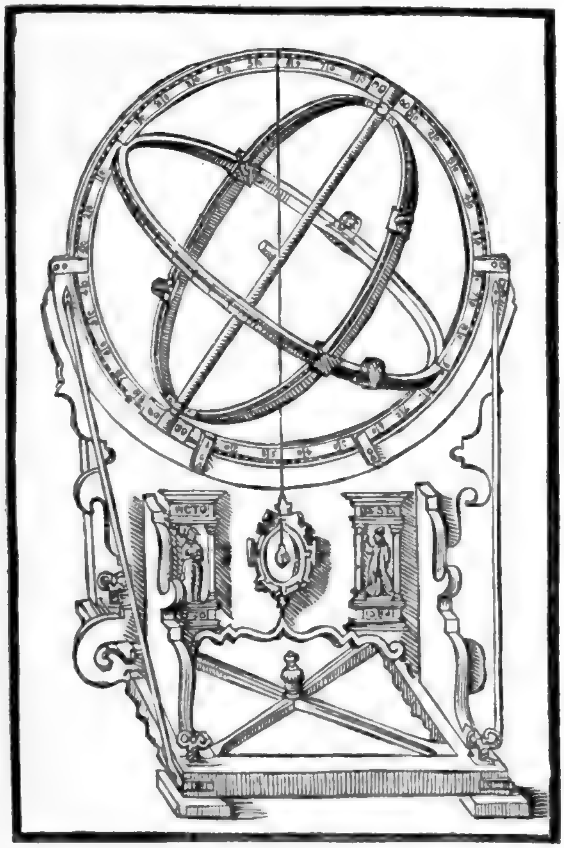


any object Q in the heavens which lies in the plane of the circle, it is obvious that, by turning the tube A B towards any other object P in the plane of the circle, the angle B O D will be the angle subtended by the two objects P and Q at the eye, or their angular distance upon a common globe. This angle may be measured, if the circumference of the circle be graduated. Thus, suppose the plane of the circle to pass through the poles N and S, and C D to point towards the equator; then when the tube points towards the star, N O B its north polar distance, or B O D its declination, may be measured; or if the circle be fixed in the plane of the equator, and C D be made to point towards the vernal equinox at the same moment at which the tube points towards the star, then the angle D O B will be the right ascension of the star.

A collection of circles, such as the *Armillary Sphere*, might therefore, by furnishing each circle with tubes, be made a complete astrolabe. The practical difficulty consists in keeping so many circles exactly in their proper relative positions. The distinction between the astrolabe of the ancients and the circular instruments of the moderns, is as follows:—First, the ancients endeavoured to form an astrolabe of two circles, so as to measure both latitude and longitude, or both right ascension and declination, by the same instrument; while the moderns, in most cases, measure only one of the two. Secondly, the ancient instruments were made to revolve, to find the star, or were furnished with at least one revolving circle, moving round the pole of the equator or ecliptic, according as declination or latitude was to be measured. The moderns for the most part fix their instruments in the meridian and wait for the star. But the *equatorial*, the altitude and azimuth *circle*, and the *theodolite*, are strictly astrolabes, according to the ancient meaning of the term.

Hipparchus is the first we know of who can be reasonably supposed to have made use of an astrolabe. But, at the same time, there are reasons for supposing that Eratosthenes, a century before Hipparchus, made use of a circle fixed in the meridian, for measuring the obliquity of the ecliptic. He is also said to have erected armillary circles at Alexandria. Ptolemy does not mention Hipparchus expressly; but he was in all respects his follower, and therefore, probably, in describing his own instrument, he is only repeating that of his great predecessor. And Nicholas Cabasillas (an ecclesiastic of the 14th century, cited by Delambre) attributes to Hipparchus an instrument consisting of an equator, a meridian, and two tropics. It is impossible, from what we know of Hipparchus, that he could have done without something of the sort. At the same time, between Hipparchus and Ptolemy we have no observations to settle this point.

The description of Ptolemy ('Syntaxis,' book v. ch. i.) is as follows:—Fix two perfectly equal circles at right angles to each other, and let one represent the ecliptic, and the other the solstitial colure. In the poles of the ecliptic place cylinders, projecting within and without beyond the rims of the solstitial colure, and fix on these cylinders as pivots outer and inner circles, which shall revolve freely without and within the first-mentioned circles. These are evidently circles of longitude. Within the innermost, and in its plane, place a lighter circle, sliding by friction, and having two sights diametrically opposite, by which the latitude of any celestial phenomenon may be observed when the instrument is adjusted; that is, when the circle representing the ecliptic is in the plane of the true ecliptic. To effect this, cylindrical pivots are inserted in the solstitial colure in the points corresponding to the poles of the equator, and the whole of the apparatus is suspended within a circle which is placed in the meridian of the place of observation. The ecliptic being divided from its interior to its exterior rim, the outer of the circles of longitude is set to the division corresponding to the longitude of the sun, as given in the solar tables, and the whole



is then turned round the poles of the equator, until the plane of the ecliptic and the plane of the outer circle of longitude pass through the sun. The instrument is then adjusted, the inner circle of longitude and its sliding limb with sights is turned to the moon, and the angle read off upon this circle is the latitude of the moon, while the angle read off on the interior edge of the ecliptic is the longitude.

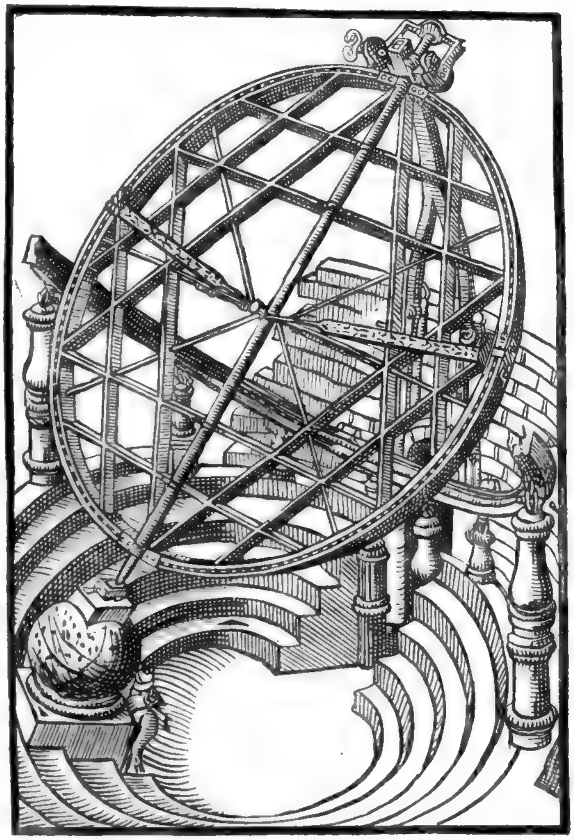
When stars are observed, it is sufficient to make the plane of the outer circle of longitude pass through the moon or any known star after setting that circle to the known longitude of the moon or star. The observation then takes place as before.

No material improvement upon this construction appears to have been made by the Arabs, who in some instances used very large instruments of the kind. A more skilful variety of the astrolabe is here shown, described by Tycho Brahé, from whose 'Astronomiæ Instauratæ Mechanica' the preceding cut is taken.

The outermost circle represents the meridian; the axis passes through the poles, and there is a revolving equator and hour-circle fixed together. The sights on the circles are moveable; but instead of using opposite sights, the small cylinder which projects from the axis is employed. For example, to measure the declination of a star, the hour-circle is moved till it passes through the star, and a sight is then placed so that the star may be seen through it on the edge of the cylindrical pin which projects from the centre of the axis, both on looking above and below the cylinder, the orifice of the sight being made just large enough to admit of this. The angular distance of the sight from the equatorial circle is then the declination of the star. To measure the difference of right ascension of two stars, two observers take two sights on the equator, which they adjust till each sees his star just on the axis, both on one side of it and the other. The angular distance of the sights is then the difference of right ascension of the stars.

The plumb-line shows whether the meridian is exactly vertical, and the screws at the feet are employed to raise or lower either end when necessary.

We give one more step between the ancient and modern instruments, from the same work of Tycho Brahé.



The hour-circle is now disengaged from the equator and independent of it. The polar axis is directly supported, and not made to depend upon the position of the meridian. This is perhaps sufficiently near to the modern equatorial to be considered as the first instrument of the kind.

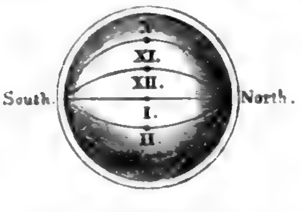
ASTRO'LOGY. If this word were used in a sense analogous with that of *geology* or *theology*, it would mean simply the *science of the stars;* while *astronomy* might mean the science of their order and arrangement. But the term, at least when coupled with the epithet *judicial*, has always signified the discovery of future events by means of the position of the heavenly bodies. The two words astrology (ἀστρολογία) and astronomy (ἀστρονομία) seem to have been used in the same sense by the Greeks, at least till about the Christian era. Cicero ('Offic.' i. 6.) uses the word *astrologia* to express astronomical knowledge.

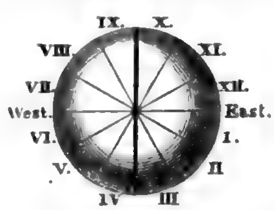
It has long been unusual to produce any arguments against this pretended science; but there are two considerations which make us think it may be useful to show those who are unacquainted with it a few of its details. The first is, that works, seriously professing to inculcate and defend the principles of astrology, have been published within the last twenty years in this country, and are still sold, almost exclusively, by some booksellers: the second, that several of our most popular almanacs do actually give astrological predictions at the present time. This may be a mere matter of amusement with the more enlightened; but we are afraid there are some who play with edge-tools in reading the fooleries of the works alluded to. The love of the marvellous is not under proper regulation, even in the minds of many who do not go the length of supposing astrology credible; and we shall therefore perhaps do good service in showing what the system really is, and what consequences its adoption must lead to.

It must moreover be remembered that our old English writers, particularly the dramatists, cannot be well understood without some information upon the leading terms and principles of this art; which therefore may be as lawfully studied as the history of Jupiter and the Metamorphoses of Ovid.

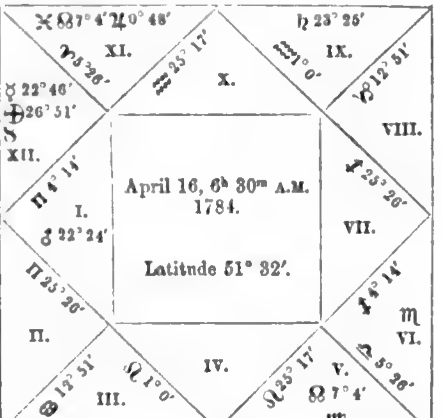
The science which, under the name of astrology, or some term of equivalent meaning, found universal belief among all the nations of antiquity except the Greeks, and also prevailed through the whole world of the middle ages, is based upon the supposition that the heavenly bodies are the instruments by which the Creator regulates the course of events in this world, giving them different powers according to their different positions. This is the description of the more learned astrologers; for we need hardly say, that the ignorant have made the stars themselves the agents, just as the image of the Deity has generally come in time to be regarded by the vulgar as the Deity himself. Looking at the more credible description, it might be philosophical for a newly created being, in possession of rational powers, to suspend his opinion on such a point till he had observed facts enough to affirm or deny the connection asserted to exist between the places of the planets and his own fortunes. That there is nothing repugnant to human nature in the basis of astrology is sufficiently proved by the number of great minds which have been led by it, when properly prepared by education; and the present age must recollect that the arguments which are now held conclusive against astrology get their strength in the minds of most people from no other circumstance than that which formerly was the prop of considerations which were held equally decisive in favour of it, namely, the bias of education. The real arguments against astrology are, first, that it is self-contradictory; secondly, that its predictions are not borne out by facts. To see the first of these, we must describe the leading principles of the art.

In the following globes, the circle projected horizontally represents the horizon, the double circle the meridian, and the other four circles are drawn at equal distances from the meridian and horizon, through the north and south points of the latter, thus dividing the whole





heavens, visible and invisible, into twelve equal parts. These circles are supposed to remain immoveable, while the diurnal revolution of the globe takes place under them. The twelve divisions are called the twelve *houses* of heaven, and are numbered in the order in which they would rise, if the circles accompanied the diurnal revolution. Every heavenly body passes through the twelve houses in twenty-four hours, but is not always in the same house with the same stars, except at the equator. For it is evident that, in order to have two bodies always in the same house, the revolution must take place round the north and south poles of the heavens, which poles are in the horizon only to a spectator on the equator itself. The principal point attended to in each house is the part of the zodiac which occupies it; and the place of any planet in the house is the distance of the body from the cusp, or boundary circle, measured on the zodiac. The following fanciful method of representing the twelve houses was in universal use, and the readers of almanacs must be familiar with it.



The twelve triangles represent the twelve houses of heaven, as marked by the Roman numerals. The time is April 16, 1784, at half past six in the morning. On the boundary of each house is written the part of the ecliptic which is to be found on it. For instance, on the cusp of the twelfth house that is just rising is the point of the ecliptic which is in 4° 14′ of Gemini. The boundary between the ninth and tenth houses is in 1° Aquarius. The whole sign of Scorpio is in the sixth house, the boundaries of which are therefore in Libra and Sagittarius. The planets are placed in their proper positions in the houses; thus Mercury (☿) appears to be in the twelfth house, at 22° 46′ from the boundary of the eleventh and twelfth.

But, on all the preceding points, it must be observed that great authorities differ very much. From among the obscurity and confusion which prevail in old treatises, we are able to collect this much, that some of them draw the boundary lines of the houses in such a way as to cut the ecliptic into twelve equal parts, instead of the prime vertical, as we have done; others draw the boundaries through the poles, instead of the north and south points of the horizon. The future destinies of mankind are rendered very uncertain by such diversity of opinion; but this we have found, that the followers of each system complain just as much of the rest, as if they had some reason to show for their own. For instance, Peletarius, or Pelletier, who introduced algebra into France, and wrote on the horoscope in 1563, expresses himself thus: "Some cut the horizon into equal parts, some a vertical circle, some the equator, some the ecliptic, some a parallel: whence it is not wonderful that a difficult art should be involved in fresh obscurity; for who can possibly see a living likeness in a mirror which is put out of shape in so many ways?" His own system is the equal division of the zodiac; and his argument for it, independently of old authorities, is the incongruity of letting the poles of the ecliptic have nothing to do with a matter which so nearly concerns the zodiac. *Minimeque convenit, zodiaco suos polos esse inutiles in eo negotio quod zodiaco maxime proprium est.* The placing of the signs in the equator he treats as a dream, and seems perfectly satisfied with the preceding reason.

The houses have different powers. The strongest of all is the first, which contains the part of the heaven about to rise: this is called the *ascendant;* and the point of the ecliptic which is just rising is called the *horoscope*. The next house in power is the tenth, which is coming on the meridian, &c. The first is the house of life; the second, of riches; the third, of brethren; the fourth, of parents; the fifth, of children; the sixth, of health; the seventh, of marriage; the eighth, of death; the ninth, of religion; the tenth, of dignities; the eleventh, of friends; the twelfth, of enemies. Each house has one of the heavenly bodies as its lord, who is stronger in his own house than in any other, as is but fit; and of two planets equally strong in other respects, he who is in the strongest house is the stronger. Now conceive all plants, animals, minerals, countries, &c., parcelled out under the different planets, which exercise their influence in abundance of different ways, according to the houses they may happen to be in for the time, and their positions relatively to each other—the result will be as good an idea of the mysteries of astrology as it is worth any body's while to obtain.

We shall now give some examples of the application of the science; and this we do principally, because in the mystical announcements which issue from our press, the darkness of the hints which are given throw a poetical gloom over the subject. This no doubt is interesting, and is not sporting too much with the credulity of the age, or with the chance of detection; but it is a foul libel on the powers of astrology. Thus, in 1815, instead of announcing some such prediction as the following—"Mars in the house of death portends, we are afraid, some new disasters by war or other cause; a personage will strive against the new order of things; but, if we mistake not, the conjunction of Luna and Saturn in the twelfth house bodes him no good,"—instead, we say, of such an unsatisfactory prophecy, a real believer in astrology, such as it was before it fell from its high estate, might have traced Napoleon from Elba to Waterloo, have calculated the very moment of the advance of the Prussians, and described the sword-knot of the captain of the Bellerophon. Thus we have the story of a Jew, in the time of the Caliph Al Mansur, who was able to detect, by means of the heavenly bodies, that certain words just written upon a paper, which he was not allowed to see, were the names of a plant and an animal. But lest any one should imagine that perhaps the later astrologers have given up the attainment of information so minute, and have confined themselves to such general indications as those of our almanacs, which, as they mean nothing, may as reasonably be drawn from the stars as elsewhere, we take the following instances from a work published in 1817, which we will not name, and which we would willingly suppose to have been written in irony, if it were not that its size (2 vols. 4to, with tables) and style are both evidences either of real belief or intentional attempt to deceive.

A man was born June 24, 1758, at eight minutes after ten in the morning, committed a murder, and was by many supposed to be insane. Pending his trial, an astrologer was requested to point out by the stars whether this defence would be established or not. The nativity was cast; that is, the position of the heavens at the aforesaid time was laid down, and the nativity having been *rectified* (a process amounting to giving the prophet a power of making almost any change he pleases), the result was as follows:—

"Mercury being lord of the ascendant, irradiated by a malefic quartile aspect of the planet Mars, and afflicted by an opposition with Jupiter, declares that the native shall be involved in an abyss of troubles and afflictions, even to the hazard of his life."—"The quartile of Mercury and Mars, particularly when Mercury is constituted principal significator, hath implication of high crimes and misdemeanors."—"Upon a further inspection of the figure, we find a baneful quartile aspect of Mars and Jupiter, with a mischievous opposition of Saturn and Mars. To the first of these we are to attribute the dissolute manners of the native."—"Here is unquestionably a favourable trine of the Sun and Saturn; but no great good can result from it, because the Sun is lord of the twelfth house, posited in the tenth, and out of all his essential dignities: at the same time that Saturn is lord of the sixth, located therein, and both the significators are under the dominion of the *evil genii*, vitiating the mind and affections of the native."—"At the time the unhappy native was prompted to commit this barbarous act, the Moon came to an opposition of Mars by direct direction, while she occupied the cusp of the seventh house, which represents the unfortunate woman."—"The Sun I find to be giver of life, posited in the tenth house, the house of justice; Mercury, lord of the ascendant, being in Gemini, *an airy sign*, and the Moon likewise in an airy sign, show the manner of the native's death, that *he would die suspended in the air;* while the opposition of four planets in the radix, and the mundane quartile of the Sun and Mars from the tenth, the house of justice, show the quality of it—namely, that it should be in due course of law, by the hands of the common hangman, and not by suicide."—"I brought up the direction of death with great nicety and precision, and found he would be plunged into eternity when the Sun came to the anaretical point of the midheaven, and met the noxious beams of the Moon and Mars in opposition, which thus constituted is ever productive of a violent death."

We now give the following opinion upon a case of a projected marriage, in which the lady, suspecting an attachment elsewhere on the part of her intended husband, inquires whether it will ever take place. The position of the heavens is supposed to be laid down at the moment of asking the question.

"The Sun is significator of the lady; and Saturn, lord of the seventh house, is significator of the gentleman. It must also be observed, that in this, and all questions relative to matrimony, Mars and the Sun are the natural significators of a woman's marriage; and Venus and the Moon are those of a man's. Now Saturn, the gentleman's significator, is remarkably well posited in the fifth house, and has Venus within his orb, applying to him by conjunction; which is a very powerful indication that his affections are sincere and honourable, and that his mind is fully bent to the marriage state. The Sun, likewise, being in a sextile aspect with Mars, the lady's significator of marriage, plainly shows her inclination to matrimony to be strongly fixed, and her affections to be perfectly sincere.

"The next thing to be considered is, whether there be any frustration or impediting aspect between these significators, and I find the Moon and Venus, the gentleman's significators of marriage, are applying to a quartile aspect with each other. This is an evident proof that the marriage is prolonged by the interference of some other woman of this gentleman's intimate acquaintance, because the aspect is made in a feminine sign; but as the Moon, in separating from Venus, applies to a perfect trine with Mars, the querent's principal significator of marriage, and also to a sextile of the Sun, her natural significator in the figure, it totally removes the evil effects of the malefic aspect, and leaves the path free and unobstructed to the gates of Hymen. This opinion is greatly strengthened by considering the mode in which their significators are severally disposed. Saturn disposes of the Sun, who is posited in the terms of Venus; and Venus, Saturn, and the Moon, are all disposed of by the benevolent planet Jupiter, who is himself disposed of by Mars, the principal significator of this lady's marriage, and who thus triumphs over every obstacle to the celebration of their nuptials. I therefore could not hesitate in declaring to the lady, in the fullest and most satisfactory terms, that the gentleman who courted her had a sincere and tender regard for her; and that, though some circumstances might have happened rather unfavourable to her wishes, yet she might rest perfectly assured that he was the man allotted to be her husband.

"Apparently well satisfied with these declarations, she proceeded to inquire in what length of time this desirable circumstance might come to pass. To gratify her wishes in this particular, I referred again to the figure where the Moon wants upwards of eleven degrees of forming a perfect sextile aspect with the Sun, the lord of the ascendant, and the same to Mars, her significator of marriage, and, therefore, by converting the degrees into time by the rule heretofore given, I fixed her marriage at about the end of three months, assuring her it could not exceed that time."

On looking at the examples we have chosen, we see that they refer to matters which are proverbially under the control of destiny. We therefore take another, which has more connection with the common affairs of life. It consists of directions for dealing in the smaller sorts of cattle, such as sheep, hogs, &c., and will fully explain the risk of such speculations.

"If the lord of the sixth and the lord of the second are in conjunction, in a good house of heaven, the querent may thrive by them (that is, small cattle); or if they be in sextile or trine, the same. The lord of the sixth, casting a friendly aspect to the part of Fortune, or being in good configuration with the depositor thereof, denotes much good to the querent by dealing in small cattle; but if, on the contrary, the lord of the sixth be unfortunate, and in evil aspect with the lord of the ascendant or second, or cast malignant rays to either of their cusps, the querent will lose by dealing in small cattle. If the lord of the sixth be in quartile, or in opposition to the dispositor of the part of Fortune, or the Moon, the querent cannot thrive by dealing in small cattle. The same if the lord of the sixth be afflicted either by Saturn, Mars, or the Dragon's Tail; or be found either retrograde, combust, cadent, or peregrine. The Dragon's Tail and Mars show much loss therein by knaves and thieves, and ill bargains, &c.; and Saturn denotes much damage by the rot or murrain."

That the ancient system of astrology contained the most contradictory assertions may be made evident in very few words. The position of the heavens at the time of birth settled every man's character of body and mind, the various fortunes he would meet with, and his relative positions with regard to friends and enemies. Thus, every one who was born at or very near the same time as Alexander the Great, in the same country, would have a right to expect a somewhat similar career; and twin brothers could never fail to have the same horoscope, and therefore the same success in life; and though the subject of a particular horoscope should travel over the whole world, and thereby come under the influence of positions of the heavens which never could have occurred at his birthplace, yet these would be always ready to tell him (when properly looked at) whether the present moment was favourable or unfavourable to any pursuit he had in view. To take a case that might have occurred: suppose two men had engaged to throw dice against each other for their whole fortunes, and that each went the night before to consult different astrologers in the same town. To them it would not be necessary to tell their names or exhibit their horoscopes; the present position of the heavens would be sufficient for pointing out a favourable hour, and if both astrologers worked by the same rules, as they ought to do, they would both arrive at the same result; that is, the same would be recommended to both inquirers, though one of them must certainly lose.

The astrologers never made any allowance for the precession of the equinoxes. Thus, though the *constellation* Aries is now in the sign Taurus, and the influences of its stars ought to have moved with them, we find that the *astronomical* Aries, or the first thirty degrees of the ecliptic, is used for the constellation. Under the circumstances, this is of little consequence; but such a practice would be fatal to *astronomy.*

That observed facts did stubbornly refuse to fulfil the predictions of the planets need hardly be told. In the 15th century, Stœffler foretold a universal deluge which should take place in 1524, in consequence of three planets being then in conjunction with a watery sign. All Europe was in consternation; and those who could find the means built boats in readiness. Voltaire mentions a doctor of Toulouse who made an ark for himself and his friends. Such a circumstance shows the hold which astrology had upon men's minds, from which, had it been true, it never could have been forced; for although a *new* truth, even when capable of easy verification, is introduced with difficulty, it is altogether absurd to suppose that a science, the correctness of which was of every-day experience, should drop and become exploded, not for want of cultivators, but of believers. The former we have, perhaps, even now, and a few of the latter, though only among the most ignorant of the community. The art is at present under the ban of the law, in order that designing persons may have at least one access stopped to the pockets of the credulous. By the Statute of the 1st of James I., c. 12, sorcery of all species was prohibited, though it does not appear certain that this term included astrology; but by the Vagrant Act, 5 Geo. IV., c. 8, sec. 4, all "persons pretending to tell fortunes, or using any subtle craft, means, or device, by palmistry or otherwise, to deceive and impose upon any of his Majesty's subjects," are rogues and vagabonds—that is, punishable by any magistrate, with three months' imprisonment and hard labour.

The history of judicial astrology, at least up to the middle of the 15th century, is very nearly that of astronomy, since the latter branch of the science, except among the Greeks, was mostly cultivated for the sake of the former. Hence to it, as to alchemy, we owe many really useful discoveries. It is a singular fact, that the first lunar tables which were constructed on the Newtonian theory were intended to be subservient to the calculation of nativities; there is no question that the necessity which the astrologer lay under, of being ready, at any moment, to lay down the positions of the heavenly bodies, produced great numbers of useful tables and observations; and the Greek works which have been preserved by the Arabs were valued principally for the use to which their mathematics could be turned in astrology. The origin of the science is beyond the reach of history, nor is it much worth while to collect all that is known on this point. It certainly came into Europe from the East, where it is mentioned in the earliest records of every nation. The Chinese are said to have placed it on the same footing with agriculture and medicine: the Chaldeans cultivated it sedulously, and the invention is attributed to them by Suidas (cited by Montucla, iv. 372). The Hindoos have long regulated the most important actions of their lives by the stars (see introduction to the 'Lilliwati'); but Mr. Colebrooke has shown ('Hindoo Algebra,' preface, p. 80) that several of their fundamental terms are not Sanscrit, from which he apparently leads us to conclude that he thinks the science neither ancient nor indigenous in India. Among the Egyptians it was of great antiquity; but it is not mentioned in the books of Moses, unless included in magic or sorcery, which is most probable.

The books of Isaiah and Jeremiah allude directly to astrology in several places, as also that of Daniel. During the captivity, the Jews appear to have learnt the art, and from that time probably, but certainly in the earlier centuries of the Christian era, became much addicted to it. Several of the more celebrated writers on astrology under the caliphs were Jews, as Messahalah, Moses ben Maimon, Solomon Iarchus, whose almanacs we have mentioned as among the earliest published, and many others.

In Greece, at least during the classical ages, judicial astrology found no reception; nor do we trace any marks of it even in the earlier astronomical writers of that country. The system was little in harmony with the allegorical mythology which prevailed there; and the oracles afforded perhaps sufficient nourishment to the appetite for the marvellous. But among the Romans astrology was cultivated with avidity from the time of the conquest of Egypt, in spite of several edicts of the senate. In the 2nd century the whole world was astrological, and even Ptolemy was infected. There is a work entitled 'Tetrabiblos' attributed to him, which is entirely devoted to astrology; and though its genuineness has been doubted by some, merely because it is astrological, there appears no sufficient reason to reject it. (See Delambre, 'Hist. Ast. Anc.,' ii. p. 543.)

All the followers of Mohammed are and have been astrologers. The predestinarian doctrines of their system render the transition easy and natural; for, as we have seen, the science of astrology is based upon the notion of the necessity of human actions. The establishment of the Moors in Spain, and the crusades, caused the introduction or the increased cultivation of the art among the descendants of the barbarians who destroyed the Roman empire; probably the former, for we have no distinct traces either of astronomy or astrology among the northern nations. But the predestinarian principle assumed a modified form more consistent with the belief of the Catholic Church. It was said that the stars only incline, but cannot compel; which position, while it left the will free, was a most convenient explanation of any failure in the predictions. The Greek and Roman Christians of the earlier centuries had in many instances received the whole of astrology; in others, the modified belief above mentioned. Origen, though he recognises the stars as rational beings, yet, in his 'Philocalia,' contends that the stars neither incline nor compel, but only prophesy or point out what men will do, without exerting any influence. He then gives a long and curious argument against their compelling power, without explaining how it does not hold equally against their predicting faculty. St. Augustin (cited by Vossius) argues against astrology altogether. The Church, in its public capacity, condemned the art in the first councils of Braga and Toledo, and in the Decretals (cited by Vossius). The doctrine of astrology was among the errors imputed to the Priscillianists. But many zealous Catholics in later time adopted the same opinions, and among them churchmen of the highest rank, such as the Cardinal d'Ailly (died in 1425), who calculated the horoscope of Jesus Christ. The astrology of comets, which is hardly yet out of date, has even been recognised by a pope: in the 15th century, Calixtus III. directed prayers and anathemas against a comet which had either assisted in or predicted the success of the Turks against the Christians.

The establishment of the Copernican system was the death of astrology; and that upon an argument not one bit stronger against it than the preceding systems for it. When it was found that the earth was only one among other planets, it soon came to be reckoned absurd by many that our little globe should be of such consequence as to be the peculiar care of the whole system. But why should the principle of non-interference have been preferred to that of the balance of power? We have lost a charming opportunity of discovering what goes on in other planets.

The last of the astrologers was Morin, best known as the opponent of Gassendi. The latter had in his youth studied and believed in the art, but had afterwards renounced and written against it. The former, who worked for thirty years at a book on astrology, and was besides an opponent of the motion of the earth, predicted his opponent's death repeatedly, but was always wrong. He also foretold the death of Louis XIII., with no better success. Since his death, which took place in 1656, the science has gradually sunk, and we believe has in no case been adopted by any real astronomer.

ASTRONOMY signifies the *laws of the stars*, and is applied generally to all that relates to the motions and theory of the heavenly bodies, as well as of the earth. If we except general terms, such as *science*, there is perhaps no single word which implies so many and different employments of the human intellect. We shall therefore confine ourselves here, to a slight sketch of the annals of the science, and a few general considerations, pointing out at the same time the articles which should be consulted for further details.

The work of the astronomer begins in the observatory, where means are provided for noting the positions of the stars. Of the instruments by which this is done, see the principle and details in the articles INSTRUMENTS (ASTRONOMICAL); CIRCLE; CLOCK; PENDULUM; OBSERVATORY; TRANSIT INSTRUMENT; &c. There are two classes of observations: the first, of known bodies, of which the places are so nearly determined that no question remains except about quantities less than a second of time, or its corresponding quantity, fifteen seconds of space [ANGLE]; and for this class the consideration what phenomena shall be observed is made to rest entirely upon the instruments, those phenomena being preferred, for the observation of which the steadiest instruments can be made. These move only in the meridian, and the star is waited for. The second class of observations, such as those of comets, double stars, and all mere appearances which require an instrument that can be pointed to any part of the heavens or can be made to follow a star, is performed by telescopes, which are made to revolve with the heavens. [EQUATORIAL.]

The second division of astronomical labour is the department of the mathematician only. The observations as they come from the instruments are subject to all the errors of the latter, and no perfect instruments can be constructed. The best circle that can be made is slightly oval; the best pivot that can be turned will not be truly cylindrical. The question now comes, in what manner to compare different species or sets of observations, so that the discordances themselves shall point out the quantity and quality of the instrumental errors; and how from thence to derive the corrections necessary for future observations. Also, how to choose the time and manner of observation, so that any particular error, whether of instruments or theory, shall be least, if the observer be desirous of avoiding it, or greatest, if he wish to detect and measure it. Every-day experience shows that there is no better test of the progress of observation than the discovery of new instrumental errors, provided only the quantities in question become less and less. The angular error which now sets an observer to work to correct his result, is less than the six-hundredth part of that which would have been sufficient to annoy Ptolemy or Hipparchus. And in speaking of an instrument, we may consider the observer himself as a most material part, on the combined power of whose eye, ear, and judgment, the correctness of the observation depends. It is hardly to be expected that, even under precisely the same circumstances, two observers should note the same phenomenon so as to agree within a small fraction of a second; and recent experiments on phenomena noted with both the eye and hand, have demonstrated the existence of small differences between different observers, attributable only to their different habits of perception or physical constitution. On this point see EQUATION (PERSONAL).

When observations have been, as nearly as possible, freed from instrumental errors, the next step would be, if we could imagine a system of astronomy only in its infancy, with instruments as near perfection as our own, to deduce, by combination of mathematical reasoning and calculation, the real places of the stars for some one moment, and the magnitudes and laws of the various motions to which they are subject, whether periodical or permanent, and whether arising out of the motion of the earth, or out of a proper motion of the stars themselves; and for the solar system, to determine the relative motions and positions of the planets and their satellites, which can only be done by the previous measurement of the earth, and subsequent comparison of the results of one observatory with those of another. But these primitive determinations have always been in progress with the instrument, and results have increased in accuracy with the power of observing; so that instead of working afresh for the determination of *elements*, as they are called, almost the whole of modern astronomy is a process of correction of those which have been previously obtained. This greatly facilitates operations [for the reason of which see DIFFERENTIAL CALCULUS; APPROXIMATION]. The measurement of the earth itself, and the determination of its figure, which is the basis of planetary astronomy, so far as ascertaining the actual dimensions of our system is concerned, will be treated as a separate science under the name of GEODESY, though it is a constituent part of astronomy, both as to the methods by which it is carried on, and the objects for which it is undertaken.

The third department of astronomy, being that which requires the most extended knowledge of mathematics and the highest exercise of thought, is that which goes under the name of *physical astronomy*, and consists in the combination of the various phenomena as actually observed, in order to find out what are their physical causes and according to what laws those causes act. It is evident, that without some success in this branch of the science, there can be no power of *prediction*, except what arises from the presumption that preceding phenomena have run their whole possible round, so that nothing *can* happen except a repetition of what *has* happened. To a rough view this seems to be the case, and is so in a great measure; but to the instruments of an observatory there appears no such complete *periodicity*. To this head we should refer such questions as those of REFRACTION; ABERRATION; GRAVITATION. The term physical astronomy is usually applied to investigations connected with the latter only; but both etymology and analogy warrant its extension to the former. Under this, also, we must place all questions connected with the physical constitution of the various planets, so far as that can become known. Of the great increase which the predicting power of astronomy has received since Newton deduced the motions of our system from the simple law of attraction, there is no need to speak; but we shall notice one peculiar use of that principle, by which the results of observation are anticipated, and the first and second of our divisions of astronomy advanced, while at the same time the *experimentum crucis* of the truth of the principle is furnished. There are many small inequalities of the solar system, which, though not likely to show themselves mixed up as they are with so many others, are yet certain to be found, if looked for at the time when their effects are most sensible. The results of theory point out that a certain inequality, whose law and approximate magnitude it gives, should be found in the motion of a certain body, if the Newtonian principle be correct. On being looked for in the manner which the nature of the inequality itself shows to be most advantageous, it is found accordingly, and its *exact* magnitude, as ascertained by observation, is often of use in correcting that obtained from theory. For example, had it not been for methods of this kind, our knowledge of the motions of Jupiter's satellites, which is yet far from mature, would have been in a state of the merest infancy.

If the theory had arrived at a degree of completeness, towards which it has been and is rapidly tending, nothing more would be necessary for the determination of the motions of the solar system than the knowledge of the actual positions, velocities, and directions of the velocities of the bodies composing it, at some one moment, or of any other quantities in which the above were mixed up, and from which they could be obtained by calculation. But up to the present time it has been necessary to use more *data* of observation than the preceding, and it is only in recent years that tables of the moon, from the first-mentioned *data* alone, have been published,

For the details of the actual state of astronomy we must refer the reader to such articles as STARS; SOLAR SYSTEM; &c., and the names of the several planets. We shall now proceed to a sketch of the history, or rather the *annals*, of astronomy, referring for fuller information to the list of works given at the end of this article.

The real history of *written* astronomy, that is, of actually recorded and moderately correct observations in sufficient number to constitute a body of science, commences with Hipparchus, about 160 years before our æra. Prior to his time, it is difficult to do more than speculate upon the few facts which are left to us. That astronomical observation of a certain description began in the very earliest ages, there can be no doubt; but here there could be but one instrument, the horizon, and but one theory, the actual motion of the heavenly bodies round the earth. The earliest observations mentioned are those of the rising and setting of stars, which led to the registration of the different appearances presented by the heavens in the course of a year, to which may be added lunar and solar eclipses and comets. The rapid motion of the moon in the heavens would probably have caused the lunar zodiac to be first marked out, though it is clear that the solar zodiac was of a very early date. Astronomical observation has always been one of the accompaniments of civilisation, both in modern and ancient times; and however much we may conceive ourselves entitled to look down upon the notions of our predecessors, we must not forget that in speaking of any country which possessed an astronomical theory worth so much as laughing at in modern times, we place that country in the list of exceptions to the rule which prevailed through the greater number. If the Chaldean system appear insufficient or the Ptolemaic complicated, these are yet real results of thought, and, to a certain extent, actual representations of fact. Mungo Park mentions an African tribe, whose opinion it was that the inhabitants of the west fried the sun when he got down to them, and after heating him sufficiently for next day's service, took him round by a private passage to the east. If we could collect the astronomy of the whole ancient world, there can be little doubt that the comparatively humble efforts to which we are coming would appear miracles of sense and reflection, among theories not much superior to those of Park's Africans.

The nations who are known to have cultivated astronomy before the Christian era are the Chinese, Indians, Chaldeans, Egyptians, and Greeks. The first made it a matter of politics, the three next of religious observance, and all four applied it to astrology. Among the Greeks only, the science had no reference either to politics, religion, or soothsaying; and here it throve with a vigour which permits us to make the astronomy of Hipparchus and Ptolemy a part of the chain which ends with Newton and Laplace. What we know of the four first-mentioned nations is not sufficiently certain or definite to warrant our drawing very positive conclusions as to the time when they began to study the science; and the question is rendered the more difficult by the pretensions to antiquity which have been advanced in favour of each by well-informed men of modern times. Each nation has its advocates, who maintain that the Chinese, the Indians, the Chaldeans, or the Egyptians, were the first astronomers: which is of itself sufficient to prove that the question is doubtful. Fortunately it is of little consequence; and also the astronomy of the first and two last is of a character and extent which will justify our saying that, be it very ancient or not, there is nothing on the face of it which needs the supposition of any very long time having been expended upon it. The Hindoo astronomy, on the other hand, though certainly more extensive and correct, may have been, for anything that can be shown to the contrary, received from the Arabs of the middle ages. At least such is the opinion of Laplace, Delambre, and several celebrated Anglo-Indians, who have had means of knowing more of the subject than either. But this question is one of difficulty, and ought not to be considered as finally settled.

The Chinese have some annals which were translated by De Mailla, a Jesuit missionary at Pekin, 1777-1785. They claim to go back to the year B.C. 2857; but of astronomical phenomena they record hardly anything, except eclipses of the sun and the appearance of comets, and of the former nothing but the fact and the day of their happening. They state that the astronomers by profession were obliged, on pain of death, to predict every eclipse that occurred, and that, even after such phenomena were found capable of prediction, it was the practice to shout, beat drums, &c., during every eclipse, to frighten away the monster which they supposed to be devouring the sun. The mathematicians, in spite of their responsibility, were forbidden to make any alteration in their theories or methods, without the consent of the emperor. The loss of many methods, asserted to have been formerly practised, is attributed to the burning of all scientific books by one of their princes, B.C. 221. But perhaps the loss was not great; for Gaubil, who recalculated their asserted eclipses, could not verify more than one of a date anterior to the time of Ptolemy; and even that one is doubtful. The fact of the motions of the planets was known to the Chinese, but not the precession of the equinoxes, till about A.D. 400. They had also the Metonic and Calippic periods.

The question with regard to the Hindoos is not whether their astronomy is sufficiently high in its pretensions to make it worth while to inquire into its antiquity, but whether an astronomical system of a very advanced character, which certainly was found among them, is or is not as old as they assert it to be. This system is found in certain tables, called the tables of Tirvalore, which have been brought into Europe by Le Gentil, and in an original work, the 'Surya Siddhanta,' of which an account will be found under VIGA GANITA, in the BIOG. DIV.; and it may be fairly considered as about equal to the European system of the 12th century. The epoch claimed by the tables is B.C. 3102, the beginning of the Cali-yug, or iron age of Hindoo mythology, at which time a conjunction of all the planets is asserted. But this has too figurative a character; and moreover, the elements of the tables are hardly such as would have been derived from observations actually made at that period. That the epoch is fictitious may be readily believed; but the question is, was this fictitious epoch formed by Hindoos from their own observations before the Christian era, or was their system introduced by the Arabs, or by direct communication with the Greeks? On the one hand it is argued that the Indian tables, being in many respects a mean between those of Ptolemy and Albategnius, may have been derived from those two; on the other hand, the remarkable correctness of several points, and the known character of the people in question, whose advances in mathematics cannot be doubted, and whose habits have, throughout recorded history, induced them to repel all connection with foreigners, are urged in favour of the originality of their system. Those who are curious may consult Bailly's 'Hist. de l'Astronomie Indienne,' on the one hand, or Delambre, on the other; but this question has unfortunately been treated with considerable spirit of system on both sides.

The Chaldeans, according to Diodorus, had long observed the risings and settings of the heavenly bodies, as well as eclipses. They had the celebrated Metonic period of nineteen years, and it is supposed that Meton obtained it from them, though this point is doubtful. They had also other periods, the meaning of which has caused discussion. [SAROS, NEROS, SOSOS.] Simplicius, a commentator on Aristotle, and also Porphyry relate that a series of eclipses preserved at Babylon was transmitted by Alexander to Aristotle, and contained the observations of 1903 years preceding the conquest of Babylon by the Macedonians. But Ptolemy gives only a few of them, the earliest of these not reaching higher than B.C. 720. They are of the roughest kind, the times being given only in hours, and the part of the diameter eclipsed within a quarter; but nevertheless they are the earliest trustworthy observations we possess, and led, in the hands of Halley, to the discovery of the acceleration of the moon's mean motion. We find also among the Chaldeans the use of the clepsydra as a clock, of the gnomon as an instrument for measuring solstices, and of the hemispherical dial called by the Greeks σκάφη, for ascertaining the positions of the sun. By the clepsydra they were enabled to divide the ecliptic nearly into twelve equal parts, and are thus said to have invented the zodiac.

The Egyptians have left us no observations, and few astronomical relics, the meaning of which can be made very clear, though it is probable that they were the first instructors of the Greeks. Their year was of 365 days: for their method of correcting it, see SOTHIAC PERIOD. They observed eclipses, but none have come to us; they foretold comets, according to Diodorus; but as this author also mentions at the same time that they foretold future events, it becomes doubtful whether we are to understand that their predictions were successful. The idea attributed to them that Mercury and Venus moved round the sun is not mentioned by Ptolemy; whose silence on this and many other points, writing as he did in Egypt, is remarkable, unless it be admitted at once as a proof of exaggeration in the preceding accounts. The correct manner in which some of the pyramids are said to be placed north and south has always been quoted as a ground of suspicion, that these buildings had some astronomical use. The zodiac has also been attributed to the Egyptians. [DENDERAH, ZODIAC OF.] The only attempt at a measure which we have remaining is one of the diameter of the sun, the meaning of which is obscure; but if what Delambre mentions (without citing his authority) be true, that they measured time by the *distance run by a horse*, as well as by the clepsydra, we need not be surprised that Ptolemy found no assistance from their ancient observations. The story of Thales teaching the Egyptians how to find the height of the pyramids by the shadow, and that in Herodotus, of his being told by them that the sun had twice risen in the west, are, so far as their credit goes, confirmations of the opinion generally formed of Egyptian astronomy.

With regard to the astronomy of the Greeks previously to the earliest extant works, there is little to be said. The Ionian school, founded by Thales B.C. 600, followed in succession by Anaximander, Anaximenes, and Anaxagoras, added little or nothing to practical astronomy. If Thales really predicted the total eclipse of the sun, B.C. 585 [ECLIPSES], he must have succeeded in doing so by means of the Chaldean Saros, or period of 18 years and 10 days, which produces a regular recurrence of solar and lunar eclipses. The opinion of the earth's motion attributed to Anaximander rests on slender foundation. The school of Croton, founded by Pythagoras about the year B.C. 500, and sustained by Philolaus, produced no observers, though it certainly adopted the opinion of the earth's motion. Pythagoras is said to have first taught that Lucifer and Hesperus, or the morning and the evening star, are in reality one and the same planet. The following is a list of ancient philosophers to whom the opinion of the earth's motion has been attributed:—

Pythagoras.	Cleanthes the Samnite.
Philolaus.	Leucippus.
Anaximander.	Ecphantus.
Nicetas of Syracuse.	Heraclides of Pontus.
Seleucus.	Aristarchus of Samos.

Meton, B.C. 432, introduced the Luni-Solar cycle of nineteen years. In conjunction with Euctemon, he observed a solstice at Athens in the year B.C. 424. Calippus, B.C. 330, introduced the improvement of the Metonic cycle, known by his name. Eudoxus of Cnidos, B.C. 370, brought into Greece according to Pliny, the year of 365¼ days, and wrote some works, one of which exists in the poetical version of Aratus.

Pytheas, about the time of Alexander, measured the latitude of Marseille with tolerable accuracy. The work of Aristotle on astronomy is lost; and what is still more to be regretted, that of his disciple Eudemus on the history of astronomy. The poem on the Sphere attributed to Empedocles, B.C. 450, is probably much more modern.

We now come to the period of history, and of the Alexandrian school. This article being for reference only, we shall condense as much as possible the principal discoveries of the succeeding astronomers, in order of time. This could not be done in the chain of surmises mixed with history which we have just finished, since it is important to avoid confounding what is known with what is only supposed.

List of astronomers of the Alexandrian school:—

Aristyllus.	Paulus of Alexandria.
Timocharis.	Theon the Younger.
Eratosthenes.	Hypatia.
Conon.	Pappus.
Hipparchus.	Diodorus.
Sosigenes.	Theophilus.
Theon the Elder.	Cyrillus.
Ptolemy.	

Autolycus, B.C. 300. His books are the earliest which are extant in the Greek language on astronomy. They are two: 1. On the sphere in motion. 2. On the rising and setting of the stars. He appears to have considered the year as exactly 365 days.

Timocharis and *Aristyllus*, B.C. 300 (?), made the observations which afterwards enabled Hipparchus to discover the precession of the equinoxes.

Euclid of Alexandria, B.C. 300. The 'Elements of Euclid' show that the Greeks of his time had no trigonometry. There is another work attributed to him, entitled 'Phenomena,' which is no more than a treatise on the doctrine of the sphere.

Aratus of Cilicia, B.C. 281, has left an astronomical poem, chiefly taken from Eudoxus, and valuable on account of the commentary of Hipparchus.

Many other ancient writers have also written commentaries on the poem of Aratus. The following list of them is given by De Chales:—

Agesianax.	Callistratus Tenedos.
Alexander of Ætolia.	Crates.
Alexander of Ephesus.	The two Didymi.
Antigonus the Grammarian.	Eratosthenes.
Apollonius the Grammarian.	Heliodorus the Stoic.
Apollonius the Geometer.	The two Hermippi.
Aristarchus the Grammarian.	Hipparchus.
Aristarchus of Samos.	Numenius Parmenides.
Aristophanes.	Parmeniscus.
The two Aristylli.	Pyrrhus of Magnesia.
Atalus of Rhodes.	Sminthes Thales.
Bœthius.	Timotheus Zeno.
Callimachus of Cyrene.	

Aristarchus of Samos, B.C. 280. His work on the magnitudes and distances of the sun and moon is the first attempt to measure the relative distances of these two bodies, by observing their angular distance at the time of half moon. To him also is attributed the opinion that the earth revolves round the sun.

Manetho the Egyptian, B.C. 260. His history is lost, but a poem attributed to him remains. It is a description of the heavens, filled with astrology and containing no observations.

Eratosthenes of Cyrene, B.C. 240, is said to have observed with some celebrated astrolabes which he erected at Alexandria, which remained standing till the time of Ptolemy. Various works are attributed to him, for which see his Life, in the BIOG. DIV. He observed (either with a gnomon or with a meridian circle) [ASTROLABE] the obliquity of the ecliptic, and the latitude of Alexandria; and from the latter, and the fact that at Syene the sun was vertical at the summer solstice, he deduced an approximation to the earth's magnitude. His approximation makes a degree to be 700 stadia. A catalogue of stars attributed to him (the oldest extant) is probably spurious, but shows that, in and about his time, the method of referring stars to their latitudes and longitudes was not practised. His value of the obliquity of the ecliptic—11 parts out of 166 of the whole circumference—was adopted by Hipparchus and Ptolemy.

Archimedes of Syracuse, died B.C. 212. He observed solstices, and attempted to measure the sun's diameter. His writings show that trigonometry was as yet unknown.

Hipparchus of Bithynia (?), B.C. 160-125, the greatest of all the Greeks in astronomy. In his youth he wrote a commentary on Aratus. He discovered the precession of the equinoxes, by comparing his own observations with those of Aristyllus and Timocharis, or others of his predecessors. He was the first who employed processes analagous to those of plane and spherical trigonometry, for which he constructed a table of chords. He first used right ascensions and declinations, which he afterwards abandoned in favour of latitudes and longitudes. He suggested the method of referring terrestrial positions to latitude and longitude, and was probably the inventor of the stereographic projection. He determined the mean motion of the sun and of its apogee, the inequality of the sun's motion, and the length of the year, to greater exactness than his predecessors. He found the mean motion of the moon, of her nodes, and of her apogee; her parallax, eccentricity, the equation of her centre, and the inclination of her orbit. His observations also led him to suspect another inequality in the moon's motion, which Ptolemy afterwards discovered (the evection). He calculated eclipses, and used the results in the improvement of the 'Elements.' He made one of the first steps towards a correct representation of phenomena, by supposing the sun to move round the earth in a circle, the earth not being at the centre. His catalogue of the longitudes and latitudes of 1081 stars was the first at all worthy of the name. If Hipparchus had possessed the pendulum and the telescope, fifty years might have enabled his successors to place astronomy in the state in which it stood at the birth of Newton. Considering his means, his observations are perhaps unequalled.

After the death of Hipparchus there is no astronomer of eminence till Ptolemy. Between them we have—

Hypsicles of Alexandria, B.C. 146, wrote the 14th and 15th books of the 'Elements of Euclid,' which contain some astronomical propositions.

Geminus (of Rhodes?) B.C. 70, wrote an introduction to the heavenly phenomena, containing no new discovery. It would seem he was not an observer.

Posidonius about the same time attempted to verify the measure of the earth of Eratosthenes. His writings are all lost, but many of his opinions are preserved in Cleomedes and Strabo. He remarked (though probably he was not the first who did so) the connection of high water with the southing of the moon.

Theodosius of Bithynia, B.C. 50, left a work on spherical geometry, another on climates, and a third on the phenomena of day and night.

Sosigenes of Alexandria, B.C. 50, corrected the calendar under Julius Cæsar.

Hyginus left an astronomical description of the heavens.

Manilius, a Roman, A.D. 10, wrote an astronomical and astrological poem.

Seneca, A.D. 50. His book on natural philosophy contains many pieces of information on astronomical history, but is principally remarkable for the bold opinions of the author on the nature of comets. These he declares to be planets, whose laws he predicted would one day be calculated, and that posterity would wonder how things so simple could have so long escaped notice.

Menelaus, A.D. 80, observed at Rome and Rhodes. He has left three books of spherical trigonometry.

Theon of Smyrna, A.D. 117 (?) observed at Alexandria. He wrote on astronomy, and made a collection of astronomical works. His observations are cited by Ptolemy.

Cleomedes wrote on astronomy. He certainly lived after Posidonius, but whether before or after Ptolemy is uncertain. He is usually considered as having lived under Augustus Cæsar.

We must suppose that there were many real observers between the epochs of Hipparchus and Ptolemy; but from the loss of even their names, and the silence of Ptolemy himself, it is clear that no discovery of any importance was made.

Ptolemy of Alexandria, A.D. 130–150. We must briefly mention his works, his system, and his discoveries. The *μαθηματικὴ σύνταξις*, or *mathematical collection*, afterwards called *μεγάλη σύνταξις*, and by the

Arabs the *Almagest* [ALMAGEST; SYNTAXIS] is the work from which we derive most of our knowledge of the Greek astronomy. We find there a full account of the observations and discoveries of Hipparchus; those of Ptolemy himself; the reasons and elements of his system; various mechanical arguments against the motion of the earth, which show that the first principles of dynamics were utterly unknown; a description of the heavens and the Milky Way, and a catalogue of stars, which we may be nearly certain was that of Hipparchus, reduced to his own time by an assumed value for the precession, but which has been asserted to have been corrected by new observations; a theory of the planetary motions; the length of the year; the instruments he employed, &c.

The Ptolemaic system [for more detail of which see PTOLEMAIC SYSTEM] was an attempt to represent the motions of the planets by supposing them to move uniformly in circles, the centres of which circles themselves moved uniformly in circles round the earth. The angular motions of the planets, as then known, were sufficiently well represented by this system; not so their changes of distance from the earth, as seen in their apparent diameters. This was the universal system of after-times till Copernicus.

The principal discovery of Ptolemy is that of the LUNAR EVECTION (which see), an inequality such as would be caused by an alternate increase and diminution of the eccentricity of the moon's orbit. He also discovered the REFRACTION (which see), and made some tolerably correct experiments to determine its law. He explained the apparent enlargement of the discs of the sun and moon when near the horizon. He extended the projection of the sphere of Hipparchus. He entered into the investigation of every point which Hipparchus had touched; in some instances finding more correct values; in others, altering without amending. He was not an astronomer only, but wrote on geography, music, chronology, mechanics, and, unfortunately, on astrology.

With Ptolemy the originality of the Greek school ends. We must come to the Arabs before we find anything worth particular notice.

Sextus Empiricus, A.D. 173, described and wrote against the Chaldean astrology.

Censorinus, A.D. 238, wrote an astrological work on the day of nativity, containing historical information with regard to astronomy.

Julius Firmicus Maternus, A.D. 370, wrote on astronomy.

Pappus of Alexandria, A.D. 383. His commentary on Ptolemy is nearly all lost.

Theon of Alexandria, A.D. 385, the most celebrated commentator on Ptolemy. He was a good mathematician, but no great astronomer. He has however left some tables, and a method of constructing almanacs.

Hypatia (his daughter), murdered A.D. 415, the first female on record celebrated for her scientific talents. She wrote one book of her father's commentary, and constructed some tables.

Martianus Capella, A.D. 470, in his 'Satyricon,' has some astronomical notions, among which is the following: that Mercury and Venus move round the sun. Cicero and Macrobius give the same idea; but the passage of Martianus is remarkable as being reported to have turned the attention of Copernicus to the system which bears his name.

Thius of Athens, A.D. 500, has left six observations of lunar occultations and solstices: *the only observations recorded between Ptolemy and the Arabs.*

Simplicius, A.D. 546, has left a commentary on, and description of, the astronomical work of Aristotle, which we have mentioned as lost.

Proclus Diadochus (the commentator of Euclid), A.D. 550, wrote a commentary on the astrology of Aristotle, and a description of astronomical phenomena.

Isidore, archbishop of Hispalis (Seville), A.D. 636, wrote a theological work on astronomy.

Bede, A.D. 720, and *Barlaam* the monk, A.D. 1330, are attached to the preceding by Delambre. Both wrote astronomical works of little distinct merit. The last Greek writer on astronomy of the least note is *Michel Psellus*, A.D. 1050.

It is remarkable that, excepting his own commentators, few of the authors who flourished during the period immediately succeeding ever quote Ptolemy. Had it not been for the Arabs, the writings of the latter must have been lost.

The Alexandrian school was destroyed by the Saracens under Omar, A.D. 640; and the rise of astronomy among the eastern Saracens dates from the building of Bagdad by the Caliph Al Mansur, in the year 762. In the reign of this prince translations of the Greek writers were begun; and, with nearly the same instruments and the same theory as Ptolemy, a career of four centuries of observation commenced, during which many astronomical elements, and in particular the obliquity of the ecliptic, and the precession of the equinoxes, were more accurately determined.

In the reign of Al Mamoum, son of Harun al Rashid, himself a diligent observer, great encouragement was given to astronomy. A degree of the meridian was measured, but with what accuracy cannot be known, from our ignorance of the measure employed.

Albategnius, or *Al-Batani*, A.D. 880, discovered the motion of the solar apogee, corrected the value of the precession, the solar eccentricity, and the obliquity of the ecliptic, and published tables. He is the first who made use of sines (instead of chords) and versed sines. He found the length of the year more accurately. He is, beyond all doubt, the only distinguished observer of whom we know anything between Hipparchus and Tycho Brahé.

Alfraganus, or *Al-Fergadi*, and *Thabet ben Korrah*, both about A.D. 950. The first has left a work on astronomy; the second is principally remarkable by his having revived an old notion of the Greeks (not mentioned by Ptolemy, but by Theon) of a variation in the position of the ecliptic, which has been called a *trepidation*. (See 'Hist. Ast.,' Library of Useful Knowledge, p. 33.)

Ebn Yunis, and *Abul-Wefa*, about A.D. 1000. The former, an Egyptian, an observer and mathematician of great merit, has left a work containing tables and observations. He first noted the time of the beginning and end of an eclipse by taking the altitude of a star. His work shows an increasing knowledge of trigonometry. He was the first who employed subsidiary angles. Abul-Wefa first formally used tangents, cotangents, and secants, which Albategnius had overlooked. He gave tables of tangents and cotangents.

Alphetragius of Morocco, 1050, attempted a new explanation of the planetary motions, not worthy of further notice.

Arsachel, a Spanish Moor, 1080, has left some tables [TOLEDO, TABLES OF] of indifferent accuracy. His contemporary, *Alhazen*, wrote on refraction. *Geber*, also a Spaniard (about 1080?), made some improvements in spherical trigonometry. He introduced the use of the cosine.

Abul Hassan, about 1200, has left a catalogue of stars, and some improvements in dialling.

We have Persian tables (of the 11th century?) translated by George Chrysococca, a Greek physician, in the 14th century; but the best known are those of Nasiréddin, published in 1270, under the protection of Hulagu, grandson of Jenghis Khan, and conqueror of Persia. The Persians have a method of intercalating their solar years, which, though complicated, is of surprising accuracy, but when they first began to employ it is unknown. [CALENDAR.]

Ulug Beg, grandson of Timur, 1433. This prince made a large number of observations at Samarcand. His catalogue of stars of the date above-mentioned, was, in its day, the most correct ever published. He also gave tables of geographical latitudes and longitudes. The Emperor Akbar (sixth from Timur, died 1605) also encouraged astronomy, and caused many Hindoo works to be translated into Persian.

In China, *Cocheou-King* 1280, patronised by Kublai, brother of Hulagu, and fifth successor of Jenghis Khan, in the partial conquest which that prince made of China, made a great number of good observations. He introduced spherical trigonometry, and rejected the ancient chronology.

Since the 15th century, astronomy has declined throughout the East. The Chinese received many methods from the Jesuits, but to little purpose. Among the Hindoos, there are very few who can understand the ancient writings. The Turks and Persians have little besides astrology. We now proceed with the chain of European astronomy.

Astronomy was introduced again into Europe by means of the Greek writers, mostly through translations from the Arabic. The first translation of the 'Almagest' was made under the auspices of the Emperor Frederic II., about 1230.

Sacrobosco (an Englishman named *Holywood*), 1220, wrote a work on the sphere taken from Ptolemy, &c. It continued for a long time in great repute. He also wrote on the Calendar. About the same time, *Jordanus* wrote a curious work on the Planisphere.

Alonso X., king of Castile, 1252, with the assistance of Arabs and Jews, formed the first European tables. They differ little from those of Ptolemy. [ALONSINE TABLES.]

Roger Bacon, 1255, wrote on the phenomena of astronomy. (For writers of this period, not worth naming, see Delambre, 'Hist. Ast. Moy.' pp. 258, 444.)

The Cardinal *Cusa*, 1440, wrote on the correction of the Calendar. He is said to have maintained the motion of the earth.

George Purbach, 1460, extended trigonometrical tables, and published a theory of the planets based on that of Ptolemy.

John Müller, called *Regiomontanus* (died 1476), made an abridgment of the 'Almagest,' published more extensive trigonometrical tables, extended various parts of trigonometry, and was an observer, though not, in this respect, superior to some of the Arabs. His almanacs were the first which were worthy of the name, and were in great repute.

The two last-mentioned writers deserve some special notice, though it cannot be said that they made any direct advances either in theory or observation. Their writing, and the facilities afforded by their tables, undoubtedly did much to promote a taste for astronomy.

George of Trebizond, called *Trapezuntius*, who died 1486, first translated the '*Almagest*' *from the Greek* into Latin.

Bianchini, 1495, published tables similar to those of Alonso.

Waltherus (died 1504), a pupil of Regiomontanus, made numerous observations which were often reprinted.

The following names are inserted that the reader may know to what names to refer for the astronomy of the time immediately preceding the promulgation of the system of Copernicus. Except in this point of view, there is but little interest attached to their labours:—

Riccius, 1521, wrote a work on astronomy, containing much historical discussion.

Werner (died 1528), gave a more correct value of the precession.

Stöffler (died about 1531), published almanacs for fifty years; wrote on the astrolabe, &c.

Munster (died 1552), wrote on clocks and dials.

Fracastorius (died 1543), wrote on the heavenly motions.

In 1528, *Fernel*, who died in 1558, gave a very correct measure of a degree of the meridian, from such insufficient observations, that, as Delambre remarks, the correctness must have been accidental.

Phenomena observed to the close of the 15th century :—

1030. A total eclipse of the sun, observed in Norway.

1106. A great comet appeared. Its tail was compared to a beam of fire extending along the heavens.

1140. Occurrence of a total eclipse of the sun which was visible in London. This eclipse is mentioned in the Saxon Chronicle and in the writings of William of Malmesbury.

1264. Apparition of a great comet in the heavens, accompanied by a tail 100° in length.

1402. Two great comets appeared in the heavens in the course of this year.

1433. Occurrence of a total eclipse of the sun which was visible in Scotland.

1456. Apparition of a great comet which spread universal terror throughout Europe. This is known to have been one of the apparitions of Halley's comet.

1468. A great comet visible : observed in Europe and China.

1472. A great comet observed both in Europe and China. In one day it described an arc of 40°.

Copernicus, born 1473, died 1543. Applied himself to astronomy from 1500. In 1530, he had finished his tables of the planets, and his work 'On the Revolutions of the Heavenly Bodies,' containing an explanation of the COPERNICAN SYSTEM, which, it is almost unnecessary to say, was a revival of the opinions of the Pythagorean school on the motion of the earth. It was published in 1543, and its author died immediately afterwards. Copernicus improved the lunar tables, and gave, to a considerable extent, an explanation of celestial phenomena upon his own system. His book is a mixture of his own original and sagacious notions and of the old philosophy; and he was far from being able to answer the mechanical objections of his time. What might have struck so bold a thinker, had he lived to face opposition, cannot be told, but as the history stands, we shall come to the time of Galileo before we find all objections satisfactorily answered.

From this period, at which the preservation of printed works commences, our limits will not permit our giving more than the names of many astronomers. The following is the list of those who are worth mention between Copernicus and the death of Tycho Brahé. The history of this period has been elucidated chiefly by Professor De Morgan. The dates are generally those of death, but where that is not known, the date in brackets is that of the publication of some work.

Copernicus	1543	Vigenera	(1578)
Gassarus	1546	Stadt	1579
Apian	1552	Schreckenfuchsius	1579
Gauricus	(1552)	Bressius	1581
Rheinhold	1553	John of Padua	1582
Piccolomini	1553	Didacus à Stunica	1584
Orontius Fineus	1555	Urstisius	1588
Gemma Frisius	1555	Raimar	1588
Royas	(1555)	Benedict	1590
Dee	(1556)	Schöner	1590
Field	(1556)	Landgrave of Hesse Cassel	1592
Bassantin	1557	Mercator	1594
Recorde	1558	Thomas Digges	(1595)
Carelli	1558	Rothmann	1596
Vinet	1564	Patricius	1597
Leonard Digges	1571	Galucci	(1597)
Ramus	1572	Pini	1598
Maurolicus	1575	Jordanus Brunus	1600
Rheticus	1576	Tycho Brahé	1601
Nonius	1577		

Of these must be mentioned—

Rheinhold, the friend of Copernicus, who formed the PRUTENIC TABLES (which see).

Recorde, the first who wrote on astronomy and the doctrine of the sphere in English.

Rheticus, editor of the 'OPUS PALATINUM,' a large trigonometrical table (which see).

Maurolicus, author and editor of several works and tables. [MAUROLICO, in BIOG. DIV.]

Nonius, inventor of an ingenious method of division of the circle, which has often caused it to be supposed that he anticipated the invention of Vernier.

Mercator (Gerard), who gave the first idea of the projection known by his name.

Jordanus Brunus, who was burnt to death at Rome in consequence of his bold opinions on the system of the universe.

Up to this time, the means of observation had been undergoing gradual improvement, more by attention to the construction of the older instruments, than by the introduction of any new principle. The Copernican theory had its advocates, but was not yet adopted by many. Algebra had been introduced into most parts of Europe, but was not yet in a state to furnish much assistance in trigonometry. Logarithms were not yet invented, nor do we find the *instruments* fixed in the *meridian*, the *telescope*, or the *pendulum clock*. The first *observer*, who made any important additions to the phenomena of the heavens as received from the Arabs, was Tycho Brahé, to whom we now come.

Tycho Brahé, born 1546, began to study astronomy 1560; commenced his observations at Huena, an island, in the Baltic, near Copenhagen, 1582; was driven from thence, 1597; died 1601. He made a catalogue of the fixed stars, more accurate than any which preceded : gave the first table of refractions : discovered the *variation* and *annual equation* (which see) of the moon, the variation of the motion of her nodes, and of the inclination of her orbit. What was essentially as great a service as any of the preceding, he discarded the *trepidation* of the precession, already mentioned, which had more or less infected all tables up to his time; he also ascertained that comets (those of his day, of course) were further removed from the earth than the moon; in fact, that they had no parallax which his instruments could discover, thus refuting the notion that they were atmospheric bodies. He greatly improved and extended the instruments in use as well as all the methods of observation.

Tycho Brahé did not admit the Copernican theory; but substituted for it one of his own, usually known by the name of the *Tychonic system*. This consisted in supposing the sun to move round the earth, but all the other planets to move round the sun, being also carried with it round the earth. This system explains all the appearances as well as that of Copernicus; and we must say (though it is always usual to reproach Tycho for refusing to admit the simple system of Copernicus) that by this means the *then* unanswerable arguments against the Copernican system were avoided. In fact, there is nothing but the *aberration of light* (a comparatively recent discovery), which is demonstrably conclusive in favour of the annual motion of the earth. [ABERRATION; MOTION (APPARENT).] The system of Tycho is said to have been promulgated by some of the ancients, at least with regard to the inferior planets.

The reformation (as it was called) of the calendar took place in 1582, under Pope Gregory XIII. As the views of those who made the change were rather theological than astronomical, we shall only here mention the fact and the disputes it gave rise to; referring for further information to CALENDAR.

From the time of the death of Tycho Brahé, to that of Newton, which forms the next great epoch in the history of astronomy, we can only dwell generally on a few leading discoveries. To enable the reader to search further, we give a table of all the names between the deaths of Tycho Brahé and Newton, which Delambre has thought worthy of any mention, with some few additions. The names mentioned from 1581 to 1727, which are not in this list, will be found in the next. The year of death is given opposite to each name; or where that is not known, the year of some publication is given in brackets. The dates are principally from Weidler, and several from Delambre, compared with those in the first edition of Lalande's Astronomy.

Tycho Brahé	1601	Metius	1635
Bayer	(1603)	Schickhardt	1635
Vieta	1603	Peyresc	1637
Gilbert	1603	Reinerius	1639
Nunez	(1605)	Horrocks	1641
Scaliger, Jo.	1609	Galileo	1642
Clavius	1612	Gascoigne	1644
Pitiscus	1613	Herigonius	(1644)
Calvisius	1615	Langrenus	1644
J. B. Porta	1615	Bartoli	(1644)
Wright	1615	Rheita	(1645)
Fabricius	1616	Fontana	(1646)
Magini	1617	Cavalerius	1647
Napier	1617	Longomontanus	1647
Ursinus	(1619)	Torricelli	1647
Tarde	(1620)	Durret	(1649)
Marius	1624	Argoli	1650
Adr. Romanus	1625	Descartes	1650
Gunter	1626	Scheiner	1650
Snellius	1626	Wing	(1651)
Wendelinus	(1626)	Petavius	1652
Blaeu	(1628)	Crabtree	1652
Vlacq	(1628)	Pascal	1653
Briggs	1630	Gassendi	1655
Malapertius	1630	Licetus	1656
Vernier	(1631)	Morinus	1656
Mœstlinus	1631	Tacquet	1660
Kepler	1631	Street	(1661)
Lansberg	1632	Malvasia	(1662)
Stevinus	1633	Levera	(1663)
Bartschius	1633	Cunitia (Maria)	1664
Byrgius	1633	Deusingius	1666
Norwood	(1633)	Lubienietsky	(1667)
Habrecht	1634	Townley	(1670)

Riccioli	1671	Huyghens	1695
Mutus	(1673)	Richer	1696
Roberval	1675	Hooke	1703
De Billy	1679	Marquis de l'Hopital	1704
Borelli	1679	Duhamel	1706
Doerfel	(1680)	Gregory, Dav.	1708
Picard	1682	Roemer	1710
Lefevre	1683	Cassini, Dom.	1712
Picard	1684	Cotes	1716
Hevelius	1687	Leibnitz	1716
Pound	(1687)	Lahire, Phil.	1718
Greenwood	(1689)	Lahire, Gabriel P.	1719
Seth Ward	1689	Flamsteed	1719
Auzout	1693	Keill	1721
Bouillaud	1694	Wren	1723
Mercator, N.	1694	Wurzelbaur	(1725)
Mouton	1694	Newton	1727
Buot	1695		

As we approach an age in which discoveries proceed rapidly, it would disturb the order of time if we were to enumerate those of individuals together. We shall therefore give the dates in chronological order of the more remarkable phenomena which have appeared, and of the principal accessions to the science, keeping, according to our original plan, only enough to direct the attention of the reader to points worthy of further reference.

1560. Occurrence of a total eclipse of the sun which was observed at Coimbra by Clavius.

1567. Occurrence of an annular eclipse of the sun.

1572. Apparition of a new star in the constellation Cassiopeia. Hagecius determines the apparent positions of the new star of this year by measuring its altitude on the meridian and noting the time of observation.

1573. Thomas Digges proposes to determine the positions of the celestial bodies by the method of corresponding altitudes.

1577. Apparition of a comet, the observations of which enabled Tycho Brahé to demonstrate that cometary bodies revolve in the regions beyond the moon.

1581, or thereabouts, Galileo remarks the isochronism of the pendulum.

1590. An occultation of Mars by Venus witnessed by Mœstlin. (A doubtful observation.)

1596. Kepler's 'Mysterium Cosmographicum,' containing fanciful analogies between the orbits of the planets and the regular solids of geometry.

1598. Occurrence of a total eclipse of the sun which was observed in the north of Europe.

1601. Occurrence of an annular eclipse of the sun observed in Norway.

1603. Bayer's maps, in which the stars are first denoted by letters.

1604. Kepler approximates more nearly to the law of refraction. A new star appears in the constellation Serpentarius.

1607. An apparition of Halley's comet.

1608. Telescopes invented in Holland by Lipperhey, a spectacle maker.

1609. Galileo made a telescope from a general description of a magnifying instrument made by Lipperhey. He used a concave object glass, Lipperhey a convex. Kepler publishes his work on Mars, in which he establishes, from Tycho Brahé's observations, the elliptic form of the orbit, and the proportionality of the areas to the times. These are called *Kepler's first and second laws.*

1610. Galileo announces the discoveries of Jupiter's satellites—of spots on the moon—of nebulæ—of some new appearances in Saturn, afterwards found to proceed from the ring—phases of Venus. He also discovers the diurnal libration of the moon, and that in latitude. Harriot observes the spots on the sun. (This fact has only been known from examination of Harriot's papers in the present century. It appears he got telescopes from Holland.)

1611. Lyncean academy founded. Galileo observes the spots on the sun.

1614. Napier's invention of logarithms.

1616. Prohibition of the theory of Copernicus by the Roman court.

1617. Snellius measures an arc of the meridian at Leyden. This was the first done by *triangulation ;* but astronomical instruments were not yet sufficiently perfect to make this method much better than the old one.

1618. *Kepler* announces *his third law*, that the squares of the periodic times of the planets are in proportion to the cubes of their distances from the sun. Apparition of a great comet with a tail upwards of 100° in length.

1619. Snellius discovers the law of refraction from one medium into another.

1626. Wendelinus determines the diminution of the obliquity of the ecliptic. He also extended Kepler's law to Jupiter's satellites, and ascertained the sun's parallax.

1627. The 'Rudolphine Tables' published by Kepler, from the observations of Tycho Brahé.

1631. Gassendi first observed the transit of Mercury over the sun's disc; he also measured the diameter of the planet. Vernier publishes his invention of the instrument which bears his name.

1633. Norwood measured the meridian from York to London, and gave a more accurate value of the degree than his predecessors. Descartes produced his system of vortices. Galileo is obliged to recant his Copernican opinions by the Inquisition of Rome.

1637. Horrocks suspects the long inequality in the mean motions of Jupiter and Saturn.

1638. Horrocks ascribes the motion of the lunar apsides to the disturbing force of the sun, and adduces the oscillations of the conical pendulum as an illustration of the planetary movements.

1639. Horrocks and Crabtree first observed a transit of Venus over the sun's disc. The former ascertained the diameter of Venus. They were the only two who saw this particular transit.

1640. Gascoigne applied the telescope to the quadrant, and a micrometer to the telescope.

1646. Fontana observes Jupiter's belts.

1647. 'Selenographia' of Hevelius, in which the moon's libration in longitude is announced.

1650. Scheiner constructs a convex object-glass telescope.

1651. A transit of Mercury observed by Shackerley, at Surat in India.

1652. A great comet visible in the heavens.

1654. Huyghens completes the discovery of Saturn's ring.

1655. Huyghens discovers a satellite of Saturn (Titan).

1657. Academia del Cimento founded.

1658. Huyghens made the first pendulum clock.

1659. Huyghens, without being aware of what Gascoigne had done, devises the original form of the micrometer as used on the continent.

1660. Mouton applied the simple pendulum to observations of differences of right ascension, and measured the sun's diameter very correctly by it.

1661. A transit of Mercury observed at Dantzig by Hevelius.

1662. Royal Society of London incorporated. Cassini begins his researches on refraction. Malvasia's improvement of Huyghens' micrometer.

1663. Gregory makes his reflecting telescope.

1664. Hooke detects the rotation of Jupiter.

1665. Cassini determines the time of rotation of Jupiter, and publishes the first Tables of the Satellites. Hooke proposes to measure the distance of the moon from the stars in her vicinity, by means of *a rete or divided scale.*

1666. Cassini determines the rotation of Mars, and makes a first approximation to that of Venus. Academy of Sciences founded at Paris, and observatory first thought of and commenced in the following year. Auzout applied the micrometer to the telescope without any knowledge of Gascoigne. Newton first turned his attention to gravitation.

1667. Auzout and Picard applied the telescope to the mural quadrant, without knowing that Gascoigne had preceded them.

1668. Cassini's second Tables of Jupiter's Satellites. 'Cometographia' of Hevelius. A great comet visible in southern latitudes.

1669. Newton made his first reflecting telescope.

1670. Mouton's first use of interpolations.

1671. Picard and La Hire publish their degree of the meridian, obtained by measuring from Paris to Amiens. Richer, in a voyage to Cayenne, observes the shortening of the seconds' pendulum in approaching the equator. Flamsteed begins observing at Derby. Cassini begins the observations which led to his discovery of the inclination of the lunar equator, and the coincidence of its nodes with those of the orbit. Cassini discovers a satellite of Saturn (Japhet).

1672. Cassini discovers a satellite of Saturn (Rhea).

1673. Huyghens publishes his 'Horologium Oscillatorium,' in which are found the first theorems on central forces and centrifugal force. Flamsteed explains the equation of time. Picard, in the course of his labours at the Royal Observatory of Paris, introduces the practice of determining the positions of the stars by observing their altitude on the meridian and noting the corresponding time.

1674. Hooke revived the idea of attraction, but without assigning any law, or connecting it with any observed facts. Spring watches made under the direction of Huyghens, who was unacquainted with what Hooke had already done in the matter.

1675. Roemer announces his discovery of the velocity of light by means of Jupiter's satellites. Greenwich Observatory founded. D. Cassini discovers the division on Saturn's ring. Roemer recognises the advantages of the transit instrument for determining the right ascensions of the stars.

1676. Flamsteed commences his observations at the Royal Observatory, Greenwich.

1677. A transit of Mercury observed at St. Helena by Halley.

1679. Halley published his Catalogue of Southern Stars, observed at St. Helena. Appearance of the 'Connaissance des Tems.'

1680. Flamsteed gives the law of the annual equation of the moon, and corrects the tables accordingly. A great comet appeared in the heavens. This comet is remarkable for having, on its passage of the perihelion, approached nearer the sun than any other comet recorded in history, with the exception of the great comet of 1843. It is also memorable for having conducted Newton to the important discovery that comets revolve in conic sections around the sun, conformably to Kepler's laws. Clement, a London clockmaker, introduces the use of anchor pallets in clocks.

1681. Doerfel's work on comets.

1682. An apparition of Halley's comet. Newton, who had laid aside his theory of gravitation when he found it not capable of verification by taking the best measures of the earth in use, hears of Picard's more accurate measurement, tries it, and finds a remarkable degree of nearness to the result deduced from his celebrated law.

1683. Cassini and La Hire discontinue till 1700 the arc begun in 1680. A mural quadrant is erected in the plane of the meridian, at the Royal Observatory of Paris. Cassini's earliest researches on the zodiacal light.

1684. Cassini discovers two satellites of Saturn (Tethys and Dione).

1687. Newton publishes the 'Principia.'

1689. Roemer first used the transit instrument; that is, fixed a telescope in the meridian for the purpose of observing transits. Flamsteed commences his course of observations with the mural arc.

1690. Huyghens' theoretical determination of the ellipticity of the earth. Catalogue of Hevelius published.

1693. Cassini's third tables of Jupiter's satellites. Announcement of his discoveries on libration. Halley discovers the acceleration of the moon's mean motion.

1694. Commencement of Newton's correspondence with Flamsteed respecting observations for the improvement of the lunar theory and the establishment of the theory of refraction.

1699. Occurrence of a total eclipse of the sun, visible in the North of Europe.

1700. The Cassinis (D. and J.) extend the arc which the former had begun southward.

1702. La Hire's researches on the theory of refraction.

1704. Roemer commences observing the stars with a meridian circle.

1705. Halley first predicted the return of a comet, namely, that of 1759.

1706. Occurrence of a total eclipse of the sun, which was visible in the south of France.

1711. Berlin Observatory founded.

1714. J. Cassini discovers the inclination of the orbit of Saturn's fifth satellite.

1715. Occurrence of a total eclipse of the sun, which was visible in London. Taylor's researches on the theory of refraction.

1718. Bradley publishes his tables of Jupiter's satellites. J. Cassini and Maraldi complete at Dunkirk the arc begun by Cassini.

1719. Maraldi's (I.) researches on the rotation of Jupiter.

1721. Halley communicates to the Royal Society Newton's Table of Refractions.

1724. Occurrence of a total eclipse of the sun, which was visible in Paris.

1725. Flamsteed's 'Historia Cœlestis.' Petersburg Observatory founded. Harrison's compensation pendulum.

1726. Bianchini determines the rotation of Venus. Graham invents the mercurial pendulum.

1727. Bradley discovers aberration. Death of Newton.

We have now brought the history to a most remarkable epoch. The great comparative perfection of instruments, the invention of the telescope, of the micrometer, of the clock, of logarithms, the introduction of algebra, the invention of fluxions, and the establishment of the theory of gravitation, in England at least, were so many steps each of magnitude unequalled in former times. But the most meritorious labours of the preceding table are not those which make most show. It takes as much space to say that Cassini discovered a satellite of Saturn, as that Flamsteed published the 'Historia Cœlestis;' but the first might have been left to the present day without much loss, whereas the latter was a new era in sidereal astronomy. It would have done more for astronomy than the mathematical Syntaxis of Ptolemy, had it been similarly circumstanced: that is, the work of Ptolemy contained only a simple account of what had been done before, with no material improvements either in methods or instruments; whereas that of Flamsteed contained both, and gave a catalogue of stars such as had not been published before. [FLAMSTEED, in BIOG. DIV.]

The distinct part of Newton's great discovery, which is seldom well understood by any who have not studied it, is—*not* the notion of attraction, which had occurred to many among the ancients, and to Borelli, it is stated, and Hooke, among the moderns—*not the law*, which had been suggested by Bouillaud or Bullialdus—but the proof that the mechanical deductions from this law of attraction really do represent the celestial phenomena; a combination of improvements in mechanics and mathematics which none but the inventor of fluxions could have made, and a specimen of sagacity which it needed the author of the Optics to display. Still less is it true, as many believe, that the Newtonian theory is the Copernican, when they speak of Newton as the establisher of the latter. After what we have said, it is unnecessary to discuss this further than to observe, that it was Galileo who destroyed the mechanical objections to the notions of Copernicus, by the sound system of dynamics of which he was the inventor; and who re-enforced the notions of Copernicus, by arguments of the most forcible character drawn from probability. But it was Bradley who, by his discovery of ABERRATION (which see), furnished the direct and unanswerable proof of the earth's annual motion; and it is a coincidence worth remembering, that the year of the death of Newton was that of this remarkable accession as well to physics as to practical astronomy.

We shall now proceed to sketch the annals of astronomy from the death of Newton to the present time.

The interval between the death of Newton and the present time may be divided into two parts: the first reaching to the end of the century, abounding in magnificent discoveries both of analysis and observation; the remainder more distinguished by efforts to extend, correct, and methodise, the results of the first.

The following is the list of names from the death of Newton to the close of the 18th century, arranged in the same manner as the preceding:—

Leadbetter	(1728)	Wargentin	1783
Maraldi, J. P.	1729	Mayer, C.	1783
Blanchini	1729	Lexell	(1783)
Louville	1732	D'Alembert	1783
Manfredi	1739	Euler	1783
Sharp	1742	Cassini III. (De Thury)	1784
Halley	1742	Trebuchet	1784
Maclaurin	1746	Boscovich	1787
Bernoulli, J.	1748	Mason	1787
Châtelet (Mad. du)	1749	Fouchy	1788
Graham	1751	Maraldi II. (J. D.)	1788
Whiston	1755	Palitsch	1788
Marinoni	1755	Madame Lepaute	1789
Cassini II. (James)	1756	Taylor	1789
Fontenelle	1756	Favre	1790
Ximenes	(1757)	D'Agelet	1791
Bouguer	1758	Bertrand	1792
Maupertuis	1759	Legentil	1792
Godin	1760	Hell	1792
Simpson, T.	1760	Triesnecker	(1792)
Dollond	1761	Bailly	1793
Bradley	1762	Saron	1794
Lacaille	1762	Mudge	1794
Mayer, T.	1762	Emery	1794
Bliss	1764	Nieuwland	1794
Horrebow	1764	Du Sejour	1794
Clairaut	1765	Antonio Ulloa	1795
Bird	(1776)	Rittenhouse	1796
De L'Isle	1768	Pingré	1796
Beccaria	(1768)	Lorgna	1796
Frisi	(1768)	Toaldo	1797
Chappe	1769	Maraldi III. (J. P.)	1797
Long	1770	Callet	1798
Pemberton	1771	Borda	1799
Fontaine	1771	Lemonnier	1799
La Condamine	1774	Montucla	1799
Harrison	1776	Liesganig	1799
Ferguson	1776	Swanberg	(1800)
Pezenas	1776	Cassini IV. (Comte)	(1800)
Lambert	1777	Ramsden	1800
Zanotti	1782	Cousin	1800

1728. Observatory of Copenhagen destroyed by fire; the great mass of observations executed by Roemer and his successor, Horrebow, irrecoverably lost.

1729. A comet visible for six months, remarkable for its perihelion distance being greater than that of any other comet recorded in history. Bouguer's researches on astronomical refraction.

1731. Hadley's quadrant invented.

1732. Maraldi (II.) improves the theory of the satellites of Jupiter by observation. The introduction, by Maupertius, of the Newtonian theory into France. Wright's Lunar Tables.

1733. Occurrence of a total eclipse of the sun, which was visible in the northern countries of Europe.

1736. Maupertius, &c., measure an arc in Lapland, and Bouguer and La Condamine in Peru.

1737. Lacaille and Cassini de Thury re-measure the arc of D. Cassini. Clairaut improves the theory of the figure of the earth. An annular eclipse of the sun observed in Scotland.

1739. Dunthorn's Lunar Tables.

1740. J. Cassini's Astronomy published, containing many new tables from his own and his father's observations.

1744. Euler's 'Theoria Motuum,' &c., the first analytical work on the planetary motions. Apparition of a splendid comet which was visible in full daylight.

1745. Bradley discovers the phenomenon of nutation. Bird began to improve the graduation of mathematical instruments.

1746. Euler's Solar and Lunar Tables. Wargentin's Tables of Jupiter's satellites.

1747. Euler, Clairaut, and D'Alembert. Various researches in the planetary theory. Mayer's confirmation of Cassini's theory of libration, by observation.

1748. Bouguer proposes a micrometer with a divided object-glass.

Euler's prize essay on the motions of Jupiter and Saturn. An annular eclipse of the sun observed in Scotland.

1749. Euler's and D'Alembert's researches on precession, D'Alembert's on nutation, Clairaut's on the motion of the Lunar Apogee. Halley's Tables.

1750. Mayer first uses *equations of condition*. Boscovich measures an arc of the meridian at Rimini. Wright's 'Theory of the Universe.' In this work the author suggests the theory of the structure of the Milky Way, which is generally admitted in the present day.

1751. Lacaille goes to observe at the Cape of Good Hope.

1752. Lacaille measures an arc of the meridian at the Cape.

1753. Dollond makes his double object-glass micrometer. Mayer's first idea of the repeating circle. Occurrence of a transit of Mercury.

1754. Chappe publishes the solar and lunar tables of Halley. Clairaut's Lunar Tables.

1756. D'Alembert's researches on the figure of the earth; Euler's on the variation of the elements of elliptic orbits. Mayer's catalogue of zodiacal stars. Clairaut's researches on the perturbations of comets.

1757. Lacaille's 'Astronomiæ Fundamenta.'

1758. Lacaille's Solar Tables. Dollond's achromatic object-glass. Clairaut and Lalande's researches on Halley's comet.

1759. Lalande publishes Halley's Planetary Tables. Apparition of Halley's comet. Improved edition of Wargentin's Tables of Jupiter's satellites.

1760. Bird's Standard Scale.

1761. Transit of Venus. Maskelyne at St. Helena.

1762. Euler and Clairaut's researches on the perturbations of comets.

1763. Lacaille's catalogue of southern stars.

1764. Occurrence of an annular eclipse of the sun. Lalande confirms Mayer's observations of libration. Lagrange's prize essay on Libration, containing the first application of the principle of virtual velocities. Mason and Dixon begin the measurement of an arc in Pennsylvania.

1765. Harrison gains the parliamentary reward for his chronometer. Maraldi discovers the libratory motion of the nodes of Jupiter's second satellite.

1766. Occurrence of a total eclipse of the sun, which was visible in the Southern Ocean. Lagrange's theory of Jupiter's Satellites. Bailly's ditto.

1767. First 'Nautical Almanac.'

1768. Beccaria measures an arc in Piedmont, and Liesganig in Hungary.

1769. Transit of Venus. Apparition of a comet with a tail of immense length.

1770. Mayer's Solar and Lunar Tables. Discovery of Lexell's comet.

1771. Bailly's further researches on Jupiter's satellites.

1772. *Bode's law* of the distances of the planets.

1773. Lagrange's researches on the attraction of spheroids. Laplace on the secular inequalities of the solar system.

1774. Maskelyne's observations on local attraction at Schehallien.

1778. Occurrence of a total eclipse of the sun.

1780. Mason's Lunar Tables.

1781. Herschel discovers the new planet now called Uranus. Messier's catalogue of Nebulæ. Wargentin discovers that the inclination of Jupiter's fourth satellite is variable.

1782. Laplace finds the elements of the orbit of Uranus. Laplace's researches on the attraction of spheroids.

1783. Nouet's tables of Uranus. Pingré's 'Cometographie.'

1784. Laplace's researches on the stability of the solar system, on the relation between the longitudes of Jupiter's first three satellites, and on the great inequality of Jupiter and Saturn. General Roy measures a base on Hounslow Heath for the connection of the observatories of Paris and Greenwich. Herschel's catalogue of Nebulæ.

1786. Lagrange gives the differential equations for the variations of the elliptic elements.

1787. Laplace's theory of Saturn's ring, and explanation of the acceleration of the moon's mean motion. Herschel discovers two satellites of Uranus. Legendre and General Roy finish the connection of the observatories of Paris and Greenwich. Beginning of the trigonometrical survey in England. Herschel's first observations with his forty-foot telescope. Herschel discovers two satellites of Uranus (Oberon and Titania).

1788. Lagrange's 'Mécanique Analytique.' Herschel suspects that the movements of the satellites of Uranus are retrograde.

1789. Herschel measures the rotation of Saturn, and discovers two satellites of Saturn (Mimas and Enceladus). Delambre's tables of Jupiter and Saturn.

1790. Herschel determines the rotation of Saturn's ring, and suspects the existence of two more satellites of Uranus. Delambre's tables of Uranus. Maskelyne's catalogue. Brinkley appointed to Dublin Observatory.

1791. An annular eclipse of the sun observed in America.

1792. Beginning of the French survey. Taylor's Logarithms. Lalande's improved Planetary Tables. Zach's first Solar Tables, and Catalogue of Stars. A comet discovered by Miss Herschel.

1793. Laplace on the satellites of Jupiter and figure of the earth. Schroeter determines the rotation of Venus.

1795. Herschel's observations on variable stars, and separation of the milky way into stars.

1796. Establishment of the French Institute. Herschel gives strong presumptions that the rotations of Jupiter's satellites are of the same duration as their orbital revolutions. Oriani on the perturbations of Mercury.

1797. Delambre's observations on refraction. Laplace's theory of tides. Olbers publishes the method for determining the parabolic elements of a comet's orbit, which has since been generally used in Germany.

1798. Cavendish demonstrates and measures the mutual attraction of metal balls. Herschel announces his discovery of the retrograde motions of the satellites of Uranus.

1799. Commencement of the 'Mécanique Céleste.' Occurrence of a transit of Mercury. Kramp's researches on astronomical refraction.

The following list comes down to the present time (March, 1859):—

Bory	1801	Gambart	1836
Jeaurat	1803	Tiarks	1837
Méchain	1804	Colebrooke	1837
Lalande, J.	1807	Moll	1837
Cavendish	1810	Bowditch	1838
Maskelyne	1811	Rigaud	1839
Lagrange	1813	Olbers	1840
Wollaston, Fr.	1815	Poisson	1840
Messier	1817	Bouvard	1840
Burckhardt	1817	Littrow	1840
Mudge	1821	Cacciatore	1841
Herschel, W.	1822	Henderson	1844
Delambre	1822	Baily	1844
Lambton	1822	Bessel	1846
Hutton	1823	Damoiseau	1846
Bode	1826	De Vico	1848
Fraunhofer	1826	Taylor	1848
Piazzi	1826	Schumacher	1850
Laplace	1827	Cerquero	1850
Wollaston, W.	1828	Boguslawski	1851
Young	1829	Goldschmidt	1851
Fallows	1831	Colby	1852
Pons	1831	Arago	1853
Foster	1831	Walker	1853
Oriani	1832	Lindenau	1854
Zach	1832	Petersen	1854
Groombridge	1832	Mauvais	1854
Legendre	1833	Gauss	1855
Brioschi	1833	Sheepshanks	1855
Caturegli	1833	Busch	1855
Harding	1834	Colla	1857
Troughton	1835	Raper	1858
Kater	1835	Bond	1859
Brinkley	1835	Wichmann	1859
Pond	1836	Johnson	1859

1799-1804. Humboldt's voyage and observations in South America.

1800. Wollaston's circumpolar catalogue. Bode's maps and catalogue. Mudge begins his great arc of the meridian, from the Isle of Wight to Clifton in Yorkshire. Commencement of the 'Monatliche Correspondenz' (an astronomical periodical, which terminates in 1812).

1801. Lalande's catalogue. Piazzi discovers the planet Ceres. Swanberg begins the measurement of an arc in Lapland.

1802. Olbers discovers the planet Pallas. Lambton begins the measurement of an arc in India. Herschel's catalogue of Nebulæ.

1803. Cagnoli's catalogue. Herschel observes the changes in the position of double stars.

1804. Harding discovers the planet Juno. Piazzi gives the proper motion of 300 stars. Zach's solar tables.

1805. Legendre, method of least squares. Discussion on the parallax of the fixed stars, from this date to 1825.

1806. Completion of the French survey by Méchain and Delambre. Delambre's Solar Tables, and Tables of Refraction. Burg's Lunar Tables. Carlini's Tables of Refraction. Pond's catalogue of North Polar Distances (altitude and azimuth instrument). Herschel suspects the motion of the whole solar system towards the constellation Hercules. Occurrence of a total eclipse of the sun.

1807. Olbers discovers the planet Vesta. Extension of the French arc into Spain. Piazzi's catalogue of 120 stars.

1808. Lagrange and Laplace's Researches on the Planetary Theory.

1809. Troughton improves the division of graduated instruments. Ivory's Theorems on the Figure of the Earth. Publication of Gauss's 'Theoria Motus.'

1810. Groombridge's Tables of Refraction. Carlini's Solar Tables. Lindenau's Tables of Venus. Bessel's researches on the orbit of the great comet of 1807. Bessel appointed Director of the Königsberg Observatory.

1811. Lindenau's Tables of Mars. Apparition of a great comet, which continued visible to the naked eye for several months.

1812. Troughton's mural circle mounted at Greenwich. Zach's Tables of Aberration. Burckhardt's Tables of the Moon.

1813. Bessel's Refractions (from Bradley). Lindenau's Tables of Mercury. Pond's catalogue of North Polar Distances (circle).

1814. Piazzi's catalogue of 7646 stars, the best and largest extant.

Observatory of Königsberg founded. Commencement of the publication of the Königsberg Observations. Commencement of the 'Zeitschrift für Astronomie' (an astronomical periodical, which terminates in 1818).

1815. Brinkley's Tables of Refraction. Bessel's researches on Precession.

1816. Lindenau's Determination of the Nutation. Poisson's Researches on the Planetary Perturbations.

1817. Delambre's Tables of Jupiter's Satellites. Damoiseau's researches on Halley's comet.

1818. Bessel's 'Fundamenta Astronomiæ.' Pons discovers a comet of short period, now called by the name of Encke. Commencement of Von Zach's 'Correspondance Astronomique' (an astronomical periodical, which terminates in 1825).

1820. Astronomical Society of London founded. An annular eclipse of the sun observed in Holland. Reichenbach's meridian circle erected at Königsberg. Commencement of the publication of the 'Astronomische Nachrichten.'

1821. Observatory of the Cape of Good Hope founded. Bouvard's Tables of Jupiter, Saturn, and Uranus. The Greenwich Observatory first introduced circle observations by reflection. Poisson on the Precession of the Equinoxes.

1822. Paramatta Observatory founded. Harding's 'Atlas Cœlestis.' Argelander's researches on the orbit of the great comet of 1811.

1823. Beginning of the erection of Cambridge Observatory. Ivory's Researches on Refraction. Encke infers a resisting medium of very little density, from observations of the comet known by his name. Apparition of a comet with two tails, one extending in the direction of the sun, and the other in the opposite direction.

1824. Herschel, J., and South, Catalogue of Double Stars. Damoiseau's Lunar Tables. Encke determines the solar parallax from the transits of Venus in 1761 and 1769. Dorpat refractor erected.

1825. Commencement of *Berlin Zones*. Second mural circle (Jones) erected at Greenwich. Apparition of a conspicuous comet.

1826. Bessel's researches on the oscillations of a pendulum. Biela discovers the comet of short period known by his name.

1827. Astronomical Society's Catalogue. Struve's Catalogue of 3112 Double Stars. Commencement of the publication of the 'Monthly Notices' of the Royal Astronomical Society.

1828. Professor Airy discovers a long inequality in the motions of the Earth and Venus. Captain Kater's vertical collimator.

1829. Pond's Catalogue of 720 Stars. Poisson on the Attraction of Spheroids. Pontecoulant's researches on Halley's comet.

1830. Sir J. Herschel's Measures of 1236 Double Stars. Publication of the 'Tabulæ Regiomontanæ.'

1831. J. Herschel; micrometrical measures of 364 double stars. An annular eclipse of the sun observed in America. Plana's 'Theory of the Moon' (first volume).

1832. Occurrence of a transit of Mercury. Sir J. Herschel; investigation of the orbits of revolving double stars. Don Joaquin de Ferrer; determination of the solar parallax, from observations of the transit of Venus over the sun's disc in the year 1769. Sir John Herschel's catalogue of 2007 double stars.

1833. Herschel's catalogue of Nebulæ in the Northern Hemisphere. Airy obtains an important correction to the value of Jupiter's mass. Publication of the results of Lieutenant Foster's pendulum experiments for determining the ellipticity of the earth.

1834. Occurrence of a total eclipse of the sun, which was visible in North America. Sir John Herschel; Researches on the Satellites of Uranus; Dawes, micrometical measures of 121 double stars. Lubbock's theory of the moon.

1835. Brisbane's catalogue of 7385 stars. Encke's researches on planetary perturbation (continued in 1836). Encke obtains a correction of the value of the solar parallax as deducible from the transits of Venus in 1761 and 1769. Apparition of Halley's comet. Airy determines the time of rotation of Jupiter. Sir John Herschel's catalogue of 286 double stars. Johnson's catalogue of 606 southern stars. Airy appointed Astronomer-Royal. Rosenberger's researches on Halley's comet. Lehmann's researches on Halley's comet.

1836. Publication of Baily's 'Life of Flamsteed.' Biot's researches on astronomical refraction. Damoiseau's tables of Jupiter's satellites. Steinheil's experiments on the brightness of the fixed stars. An annular eclipse of the sun, visible in Scotland.

1837. Lamont's researches on the satellites of Uranus. Pontecoulant's researches on the lunar theory. Henderson determines the value of the moon's equatorial parallax. Publication of W. Struve's 'Mensuræ Micrometricæ,' containing the mean distances and angles of position of 3112 stars. Argelander's researches on the motion of the solar system in space. Wrottesley's catalogue of 1318 stars. Completion of the measurement of the great Indian arc of the meridian.

1838. Second part of Lubbock's researches on the lunar theory. Bessel determines the parallax of 61 Cygni. Hansen's new method of investigating the lunar theory. Robinson's determination of the constant of lunar nutation. Airy's catalogue of 726 stars. Lamont's determination of the mass of Uranus. Lacaille's catalogue of 9766 southern stars, published by the British Association. An annular eclipse of the sun observed in America.

1839. Le Verrier's researches on the secular variations of the planets. Henderson's determination of the parallax of α Centauri. The Imperial Observatory of Pulkowa founded. Johnson appointed Director of the Radcliffe Observatory, Oxford. Amici's double image micrometer.

1840. Observatory of Cambridge, U. S., founded. Santini; catalogue of 1677 stars. Airy's double image micrometer.

1841. Repsold's meridian circle erected at Königsberg. Hansen's researches on the lunar theory.

1842. National Observatory of Washington, U. S., founded. Peters determines the constant of nutation. Baily; determination of the mean density of the earth. A total eclipse of the sun occurs, which is visible in the southern countries of Europe. Pearson's catalogue of 520 stars. Greenwich catalogue of 1439 stars.

1843. Hansen's new method of investigating the effects of planetary perturbation, whatever be the eccentricity or inclination of the orbit. Detection of a periodicity in the recurrence of the solar spots, by Schwabe. Faye discovers the periodic comet known by his name. Apparition of one of the most splendid comets of modern times. W. Struve's determination of the constant of aberration.

1844. Sheepshanks commences his operations for the re-construction of the standard yard, which he continues to prosecute till his death in 1855. Argelander's zone observations in the Northern Hemisphere concluded. Taylor's catalogue of 11,015 stars. Transmission of local time by the electric telegraph commenced in America.

1845. Hencke discovers the planet Astræa, forming the fifth of the group of minor planets, or asteroids, revolving between Mars and Jupiter. British Association catalogue of 8377 stars. Le Verrier's researches on the theory of Mercury. Smyth's 'Cycle of Celestial Objects.'

1846. Weisse's reduction of Bessel's zone-stars comprised between +15° and −15° of declination. Airy; measurement of the arc of parallel comprised between Valentia and Greenwich. Discovery of the planet Neptune,—the result of the independent theoretical researches of Adams and Le Verrier. Publication of the results of the reduction of the planetary observations made at Greenwich between 1750 and 1830. Biela's comet, on the occasion of its return to the perihelion, is seen to separate into two parts. Brorsen discovers the periodic comet known by his name.

1847. Three new asteroids discovered during this year. Motion of the solar system in space. Erection of the Altazimuth at Greenwich. An annular eclipse of the sun observed in England. Catalogue of the mean places of 47,390 stars contained in the 'Histoire Celeste' of Lalande, published by the British Association. Hansen's discovery of two long inequalities in the mean motion of the Moon. Herschel's 'Results of Astronomical Observations made at the Cape of Good Hope.' Everest's account of the measurement of two sections of the meridional arc of India between lat. 18° and lat. 29½°. Galloway's researches on the motion of the solar system in space. W. Struve's 'Etudes d'Astronomie Stellaire.' Lassell's discovery of the satellite of Neptune.

1848. Challis; researches for determining the orbit of a planet or comet. Jacob; catalogue of double stars observed at Poonah. Lassell in England, and Bond in America, independently discover the eighth satellite of Saturn (Hyperion). Wichmann's researches on the physical libration of the moon. Publication of the Greenwich lunar reductions (1750—1830). Researches of Peters on the parallax of the fixed stars. Greenwich catalogue of 2156 stars. Discovery of a new asteroid.

1849. Discovery of a new asteroid. Shortrede's logarithms. Powell's researches on irradiation. Main proves from micrometrical measures, made during the disappearance of Saturn's ring in 1848, that the figure of the planet is strictly elliptical,—a result corroborative of the previous researches of Bessel.

1850. Lord Rosse's observations of Nebulæ. Discovery of three new asteroids. Main's catalogue of the proper motions of 875 stars. Occurrence of a total eclipse of the sun, which was observed in the Pacific Ocean.

1851. Discovery of two new asteroids. D'Arrest discovers a periodic comet. Lassell discovers two satellites of Uranus (Ariel and Umbriel). Peters's researches on the variability of the proper motion of Sirius. Occurrence of a total eclipse of the sun, visible in Norway, Sweden, and the other countries of Northern Europe. Foucault's pendulum experiments for demonstrating the rotation of the earth. Discovery of the innermost or dusky ring of Saturn. Transit Circle erected at Greenwich. Termination of the operations for measuring the great Russo-Scandinavian arc of the meridian. Gould's Astronomical Journal commences.

1851-2. Oeltzen's reduction of Argelander's zones, extending from 45° to 80° of north declination.

1852. Discovery of eight new asteroids. Publication of the American Lunar Tables. Commencement of zone observations at the Cambridge Observatory, U.S. Publication of W. Struve's 'Positiones Mediæ,' containing the mean positions of 2874 stars, of which 2682 are double. Villarceau's researches on the orbits of double stars. Rümker's catalogue of 12,000 stars. Secchi's researches on the temperature of the different parts of the sun's surface. Observations with the reflex zenith tube commenced at Greenwich. Argelander's zone observations from 15° to 31° of south declination.

1853. Apparition of a brilliant comet in the northern hemisphere. Cooper's Catalogue of 30,168 stars observed at Markree. The method of recording transits of the stars by means of electro-galvanism introduced at Greenwich. Airy's researches on ancient eclipses. Adam's researches on the secular inequality in the mean motion of the moon. Hansen's researches on the theory of the pendulum, taking into account the figure and motion of the earth. Publication of the American Lunar Tables. Encke gives a new solution of the problem of planetary perturbation. Apparition of a conspicuous comet. Discovery of four new asteroids. Hansen's Solar Tables.

1854. Occurrence of a total eclipse of the sun which was visible in Chili. Discovery of six new asteroids. Lubbock's Researches on Refraction. Captain Jacob's Catalogue of 1440 stars. Airy's Pendulum experiments in the Harton coal mine for determining the mean density of the earth. Determination of the difference of longitude of Greenwich and Paris by galvanic signals.

1855. Greenwich Catalogue of 1576 stars. Bond's Zone Observations of Small Stars near the equator (First Part). Main's Researches on Aberration and Nutation. Commencement of the publication of the 'Annales de l'Observatoire Impérial,' Paris. Main's Researches on the dimensions of the Rings of Saturn. Commencement of the American Nautical Almanac. Discovery of four new asteroids.

1856. Discovery of five new asteroids. Researches of Professor Challis on the problem of three bodies. Main's researches on the diameters of the planets.

1857. Discovery of eight new asteroids. Airy's researches on ancient eclipses. Main's researches on refraction. Carrington's catalogue of circumpolar stars. Hansen's Lunar Tables. The application of photography to astronomy makes sensible progress. De La Rue and Secchi execute photographs of the moon. Bond obtains photographs of double stars.

1858. Discovery of six new asteroids. De La Rue succeeds in executing a stereographic photograph of the moon. Le Verrier's Solar Tables. The first comet of the year found by Dr. Bruhns to be periodic, and to be identical with a comet which appeared in 1790. Dr. Winnecke discovers a comet, which he finds to be periodic, the time of revolution being somewhat more than five years. Professor Encke establishes beyond doubt the existence of a continued diminution in the time of revolution of the comet which bears his name, by means of researches prosecuted during a period of nearly thirty years. Occurrence of a total eclipse of the sun which was visible in Brazil. An annular eclipse of the sun observed in England. Completion of the calculations for determining the principal triangles of the Trigonometrical Survey of the British Isles, and deduction of the definitive results relative to the dimensions, ellipticity, and mean density of the earth. Maclear, having re-measured and extended Lacaille's arc of the meridian at the Cape of Good Hope, obtains a result which accords with the generally admitted value of the earth's figure. Apparition of a comet of unusual splendour (Donati's), which continued visible to the naked eye for several weeks.

1859. Airy's researches on the motion of the solar system in space.

The following list of public observatories now in action is taken from the 'Nautical Almanac' for 1862:—

Altona.	Leyden.
Ann-Arbor, U. S.	Liverpool.
Armagh.	Madras.
Athens.	Manheim.
Berlin.	Marburg.
Bilk.	Marseilles.
Bonn.	Milan.
Breslau.	Modena.
Brussels.	Moscow.
Buda.	Munich.
Cambridge.	Naples.
Cambridge, U. S.	Nicolaieff.
Cape of Good Hope.	Oxford.
Christiania.	Padua.
Copenhagen.	Palermo.
Cracow.	Paris.
Dorpat.	St. Petersburg.
Dublin.	Portsmouth.
Durham.	Prague.
Edinburgh.	Pulkowa.
Florence.	Rome.
Geneva.	San Fernando.
Georgetown College, U.S.	Stockholm.
Göttingen.	Turin.
Greenwich.	Upsala.
Hamburgh.	Venice.
Kazan.	Vienna.
Königsberg.	Warsaw.
Kremsmünster.	Washington.
Leipsic.	Wilna.

The enormous masses of observations which are now published every year are silently affording the means of increased accuracy in every department, and are rapidly seized and applied for the improvement of the theory.

The materials of modern astronomy are contained—1st, In the publications of scientific societies; 2nd, In the introductions to the volumes which emanate from public observatories; 3rd, In the appendices to the annual volumes of ephemerides; 4th, In journals devoted exclusively to astronomical subjects; and lastly, in the independent publications of individual authors. By far the greater part of the science is to be found recorded in the third and fourth of these distinct repositories.

The ephemerides, chiefly remarkable for the papers on astronomical subjects contained in them, are:—The 'Connaissance des Temps,' of Paris; the 'Berlin Jahrbuch,' and the 'Effemeridi di Milano.' During the course of the present century a great number of valuable papers by Lagrange, Laplace, Poisson, &c., have appeared in the 'Connaissance des Temps,' but recently the volumes have been falling off somewhat in this respect. The 'Berlin Jahrbuch,' of which Professor Encke is superintendent, maintains in the present day a decided pre-eminence among publications of this class, in so far as relates to the papers appended to each volume. The volumes of the 'Effemeridi di Milano,' for the years corresponding to the close of the last century and the beginning of the present, contain many valuable papers by Oriani, Carlini, &c. A very small number of papers only have been published in the form of supplements to the 'Nautical Almanac.'

The greater part of the astronomy of the present day is to be found in the periodicals devoted exclusively to astronomical subjects. These are:—The 'Astronomische Nachrichten,' published at Altona; the 'Monthly Notices,' of the Royal Astronomical Society; and Gould's 'Astronomical Journal,' published at Cambridge, U. S.

Works on the History of Astronomy.—Sherburn's edition of Manilius, London, 1675, contains a list and short account of a very large number of astronomers, and has been much used by succeeding authors. A somewhat similar account is given by De Chales in tome i. (pp. 74-108) of his 'Cursus seu Mundus Mathematicus,' Lugdini, 1690. Weidler, 'Historia Astronomiæ,' Vittemb., 1741, contains a valuable collection of facts and dates. Heathcote, 'Historia Astronomiæ,' Cantab., 1747. Esteve, 'Histoire Générale et Particulière de l'Astronomie,' Paris, 1755. Costard, 'History of Astronomy,' London, 1767. Bailly, 'Histoire de l'Astronomie Ancienne,' 4to, Paris, 1775; 'Traité de l'Astronomie Indienne et Orientale,' 4to, Paris, 1787; 'Histoire de l'Astronomie Moderne,' 3 vols., 4to, Paris, 1779-82. Pingré's 'Cometographie,' 2 vols., Paris, 1783. Lalande's 'Astronomie,' Paris, 1792, contains a considerable number of historical facts. 'Bibliographie Astronomique, avec l'Histoire de l'Astronomie, depuis 1781 jusqu' à 1802:' this work gives a list of every known astronomical publication, and also an enormous alphabetical list of astronomers. The historians of mathematics—Vossius, Montucla, Kästner, Bossut, and Delambre, 'Rapport Historique,' &c., Paris, 1810—treat astronomy as a part of their subject. Hutton's 'Mathematical Dictionary,' and Martin's 'Biographia Philosophica,' contain information on English astronomers which is not to be found in foreign works; and there is a good deal in the histories of the Royal Society, written respectively by Sprat, Birch, and Thomson. Small's 'Account of the Discoveries of Kepler,' 1804, contains valuable information on the earlier systems of astronomy. Laplace's 'Précis sur l'Histoire de l'Astronomie,' Paris, 1821, which is also appended to his 'Exposition du Système du Monde,' is delightfully written; and there is also much information in the historical chapters of the fifth volume of the 'Mécanique Celeste.' Voiron, 'Histoire de l'Astronomie, depuis 1781 jusqu' à 1811,' Paris, 1811, is a continuation of Bailly's 'Histoire de l'Astronomie Moderne.' Delambre, 'Histoire de l'Astronomie Ancienne,' 2 vols., 4to, Paris, 1817; 'Histoire de l'Astronomie du Moyen Age,' 4to, 1819; 'Histoire de l'Astronomie Moderne,' 2 vols., 4to, 1821; 'Histoire de l'Astronomie au dixhuitième siècle,' 4to, 1827 (a posthumous work): these various works of Delambre contain a vast amount of critical research; they are indispensable to the student of astronomical history. Airy's 'Report on the Progress of Astronomy, published in the 'British Association Report' for 1832, contains a great mass of valuable facts relative to the history of astronomy in the present century. Narrien's 'Account of the Origin and Progress of Astronomy,' 8vo, London, 1835, contains an excellent account of the progress of astronomy, especially down to Kepler's time. Whewell's 'History of the Inductive Sciences,' 1847, and the 'Supplement,' 1857, may also be consulted with advantage. Professor De Morgan, in a series of papers which have been published from time to time in the 'Companion to the British Almanac,' has thrown much valuable light on the history of astronomy in modern Europe. We give the titles of the following:—'Old Arguments against the Motion of the Earth' (Comp. 1836); 'Notices of English Mathematical and Astronomical Writers between the Norman Conquest and the year 1600' (Comp. 1837); 'References for the History of the Mathematical Sciences' (Comp. 1843); 'On the Difficulty of Correct Description of Books' (Comp. 1853); 'The Progress of the Doctrine of the Earth's Motion between the times of Copernicus and Galileo' (Comp. 1855). Jahn's 'Geschichte der Astronomie,' 2 vols., 1844. Grant's 'History of Physical Astronomy, from the Earliest Ages to the Middle of the Nineteenth Century,' 8vo, London, 1852, comprises a detailed account of the progress of the theory of gravitation; besides a history, more or less extensive, of the various other branches of astronomical science. Much historical information will be found in the Annual Reports of the Council of the Royal Astronomical Society. For the general reader, it may be well to mention the 'History of Astronomy,' and the 'Lives of Galileo and Kepler,' in the Library of Useful Knowledge; and the 'History of Natural Philosophy,' in Lardner's Cabinet Cyclopædia.

ASTY'LAR, one of the numerous compound architectural terms from the Greek *stylos* (στῦλος), column; which, having the Greek privative a prefixed to it, signifies without columns. It is a term of recent introduction, but very convenient and expressive, inasmuch as it explains at once that the building described by it is without any order of columns or pilasters, however ornate it may be in all other respects. Thus, we speak of Astylar Italian in contradistinction from the columnar class of buildings in that style, or such as are decorated with the orders. Astylar composition is not only susceptible of a very high degree of embellishment, but of a species of grandeur not attainable (that is, on the same scale) in the Palladian style, or that where an order is raised upon a basement, or even more than a single order is employed for a façade, because in the former the cornice is proportioned to the entire elevation; sometimes of greatly increased proportions, and then distinguished by the name of *cornicione*. In this country we had no examples of such *astylar* class of design, until it was introduced by Mr. Barry, in the Travellers' and Reform Clubhouses.

ASY'LUM, the Latin and English form of the Greek Ἄσυλον, which is generally supposed to be made up of *a privative* and the root of the verb συλάω, 'to plunder,' and therefore to signify, properly a place free from robbery or violence. Some, however, have derived the Greek word from the Hebrew אשל, 'a grove;' the earliest asylums, it is said, having been usually groves sacred to certain divinities. It is a pretty, rather than perhaps a very convincing illustration of this etymology, which is afforded by Virgil's expression as to the asylum opened by Romulus,—

> "Hinc lucum ingentem, quem Romulus acer asylum
> Retulit."—Æn. VIII. v. 343.

The tradition was, that Romulus made an asylum of the Palatine Hill preparatory to the building of Rome. Plutarch tells us that he dedicated the place to the god Asylæus. (Plut. 'Romul.' 9.)

Probably all that is meant by these stories is, that in those ages whoever joined a new community received shelter and protection; and even if he had committed any crime, was neither punished by those whose associate he had become, nor surrendered to the vengeance of the laws or customs he had violated. Such an asylum was not an appointed place of refuge established by general consent; it was merely a congregation of outlaws bidding defiance to the institutions of the country in which they had settled, and proclaiming their willingness to receive all who chose to come to them.

But both in the Grecian states, and in Rome, the temples, or at least some of them, were endowed with the privilege of affording protection to all who fled to them, even although they had committed the worst crimes. The practice seems to have been, that they could not be dragged from these sanctuaries; but that, nevertheless, they might be forced to come out, not only by being prevented from receiving food while they remained, but even by such compulsory measures as the application of fire to the building. (See 'Thucyd.' i. 126, 134; 'Herodot.' vi. 80.) Anything appears to have been permitted except the actual dragging forth of the criminal. Eventually, these places of refuge became great nuisances, being, especially among the Greek cities, established in such numbers as sometimes almost to put an end to the administration of justice. After Greece had become a part of the Roman empire, an attempt was made to repress this evil by an order of the senate, directed to all the pretended asylums, to produce legal proofs of the privilege which they claimed. (Tacit. 'Annal.' iii. 60, &c.) Many were put down in consequence of not being able to satisfy this demand. At last, all the asylums throughout the empire were abolished by an edict of the Emperor Tiberius. (Sueton. in 'Vitâ Tiberii.' cap. 37.)

The term Ἄσυλος was given as an epithet to certain divinities; as, for example, to the Ephesian Diana. It is also found on medals as an epithet of certain cities; in which application it probably denoted that the city or district was under the protection of both of two otherwise belligerent powers, and enjoyed accordingly the privileges of neutral ground.

After the decline and fall of Paganism, the privilege of serving as asylums for malefactors was obtained by the Christian temples. The credit of conferring this honour upon churches in general is attributed to Pope Boniface V., in the beginning of the 7th century; but more than two hundred years before, certain sacred buildings of the new religion are said to have been declared asylums by the Emperor Honorius. The asylums thus established eventually grew throughout all Christendom to be a still more intolerable abuse than those of the ancient world had been. In most countries, not only churches and convents, with their precincts, but even the houses of the bishops, came to be at length endowed with the privilege of sanctuary. In all these places the most atrocious malefactors might be found bidding defiance to the civil power. At the same time, there can be no doubt, that while in this way criminals were frequently rescued from justice, protection was also sometimes afforded to the innocent, who would not otherwise have been enabled to escape the oppression or private enmity which pursued them under the perverted forms of law. The institution was one of the many which then existed, having the effect of throwing the regulating power of society into the hands of the clergy, who certainly were, upon the whole, the class in whose hands such a discretion was by far least likely to be abused. When communities, however, assumed a more settled state, and the law became strong with the progress of civilisation, the rights which had at one time armed the church as a useful champion against tyranny, became not only unnecessary but mischievous. The church maintained a long and hard struggle in defence of its old supremacy; and in the face of the stand thus made, and in opposition to ancient habits, and the popular superstition by which they were guarded, it was only very cautiously that attempts could be made to mitigate the evil. For a long time the legal extent of the privilege of sanctuary appears to have been matter of violent dispute between the church and the civil power. In this country, it was not till the year 1487, in the reign of Henry VII., that by a bull of Pope Innocent VIII. it was declared, that if thieves, robbers, and murderers, having taken refuge in sanctuaries, should sally out and commit fresh offences, and then return to their place of shelter, they might be taken out by the king's officers. It was only by an Act of Parliament passed in 1534, after the Reformation, that persons accused of treason were debarred of the privilege of sanctuary. After the complete establishment of the Reformation, however, in the reign of Elizabeth, neither the churches nor sanctuaries of any other description were allowed to become places of refuge for either murderers or other criminals. But various buildings and precincts in and near London, continued for a long time after this to afford shelter to debtors. At length, in 1697, all such sanctuaries, or pretended sanctuaries, were finally suppressed by the Act 8 & 9 Will. III. chap. 26.

In Scotland, the precincts of the palace of Holyrood in Edinburgh still remain a sanctuary for debtors. The boundaries of this privileged place are somewhat extensive, comprehending the whole of what is called "the King's Park," in which is the remarkable hill called "Arthur's Seat." The debtors find lodgings in a short street, the privileged part of which is divided from the remainder by a kennel running across it. Holyrood retains its privilege of sanctuary as being a royal palace; but it is singular as being now the only palace in this country any part of the precincts of which is the property, or at least in the occupation, of private individuals, and therefore open to the public generally.

In England, a legal asylum, or privileged place, is called a sanctuary; and this use of the word sanctuary appears to be peculiar to the English language. Both in this country and in America, the name of asylum is commonly given to benevolent institutions intended to afford shelter neither to criminals nor to debtors, but to some particular description of the merely unfortunate or destitute.

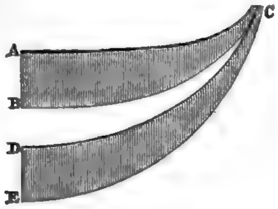
The Jewish Cities of Refuge, established by Moses and Joshua, may be quoted as the most remarkable instance on record of a system of asylum founded and protected by the state itself for the shelter of persons who had violated the law. These cities, as we are informed in the twentieth chapter of the Book of Joshua, were six in number, three on each side of the Jordan. They only, however, protected the person who had killed another unawares. This institution may be regarded as an ingenious device for protecting, on the one hand, the guiltless author of the homicide from the popular resentment, which his unfortunate act would have been likely to draw upon him: and cherishing, on the other, in the public mind, that natural horror at the shedding of human blood, which, in such a state of society, it would have been so dangerous to suffer to be weakened. We see the same principle in the deodand formerly awarded by our law in the case of the accidental destruction of life by any inanimate object.

One of the most curious instances of the privilege of sanctuary, is that long enjoyed in Scotland by the descendants of the celebrated Macduff, Thane of Fife, the dethroner of the usurper Macbeth. It is said to have been granted at the request of the thane by Malcolm III. (Canmore), on his recovery of the crown of his ancestors soon after the middle of the 11th century. By this grant it was declared that any person, being related to the chief of the clan Macduff within the ninth degree, who should have committed homicide without premeditation, should have his punishment remitted for a fine, on flying to Macduff's Cross, which stood near Lindores, in Fifeshire. Although this, however, is the account of the old Scottish historians, it is probable that the privilege only conferred upon the offender a right of being exempted from all other courts of jurisdiction, except that of the Earl of Fife. Sir Walter Scott ('Minstrelsy of the Scottish Border,') has printed a Latin document of A.D. 1291, in which the privilege to this latter extent is pleaded. The original deed still exists. Of Macduff's Cross, only the pedestal now remains, the cross itself having been destroyed at the Reformation. It bore a metrical inscription, in a strange half Latin jargon, the varying copies of which, still preserved, have given much occupation to the antiquaries.

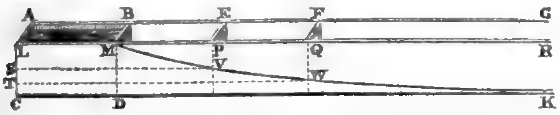
(Sibbald's *History of Fife*, second ed., 8vo, Cupar-Fife, 1802; Cunninghame's *Essay upon Macduff's Cross;* Camden's *Britannia*, by Gough).

A'SYMPTOTE (ἀσύμπτωτος), a compound Greek word signifying *which does not fall with:* if taken literally with respect to two lines, it would mean that they do not meet one another. But it is used only in speaking of two lines (one of which at least must be curved) which continually approach each other, but never meet; so that the distance between them diminishes without limit, or they may be brought to any degree of nearness, without ever actually meeting.

This appears a paradox to beginners in geometry, who are generally unable to imagine it possible that two lines should continue to approach one another for ever, without absolute contact. But this arises from their confounding the thing called a straight line in practice (which is not a straight line, but a thin stroke of black lead or ink, as the case may be) with the straight line of geometry, which has neither breadth nor thickness, but only length. And they also imagine that if two lines might be asymptotic, the fact might be made visible, which is impossible, unless the eye could be made to distin-

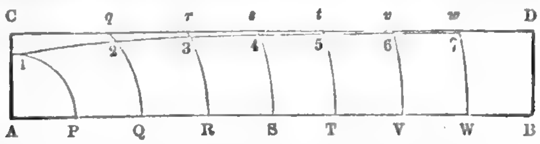


guish any distance, however small. But if the unassisted eye cannot detect a white space between two black lines, unless that space be a thousandth of an inch in breadth, which is about the truth, it is evident that two geometrical surfaces with asymptotic boundaries, such as A B C, D E C, would appear to coincide from the point where the distance between them is about the thousandth part of an inch. The idea of a geometrical asymptote is therefore an effort of pure reason, and the possibility of it must be made manifest to the mind, not to the senses. A L M B C D is a vessel of water, of which the sides and



bottom are extended indefinitely towards G and R; the end A L is fixed, but the end B M is moveable parallel to its first position, so as always to form a water-tight obstacle; by which means the length of the vessel may be increased to any extent, while its breadth and height remain the same. Let the water be a perfect fluid, without any adhesion to the sides of the vessel (which is mathematically possible, though not physically), and let the bottom of the vessel be geometrically horizontal. Then, as the end M B changes its position and moves towards G R, it is manifest that the vessel will grow larger, and the level of the water will fall. Suppose the side L K to be of glass. Thus, when the vessel ends at E P, the water may stand at S V; when the end is at F Q, the water may stand at T W, and so on. But the level of the water never can fall absolutely to the bottom C K; for so long as the preceding mathematical suppositions hold good, and there is some water in the vessel, it must stand at some determinate height above the bottom. As the end B M moves to the right, let the curve M V W, &c., mark out the positions of the level upon the edge of the moving end, as is done in the diagram. Then for the reason above given, this curve never can meet the line C K, though obviously in a state of continual approach towards it. Hence the curve M V W and the line C K are asymptotes.

As another illustration, let there be two parallel lines A B, C D, the perpendicular distance of which is A C; and from A, with different



radii, describe arcs of circles P 1, Q *q*, R *r*, S *s*, &c. From A B on all these circles measure *arcs* equal in length to the *straight line* A C; that is, let P 1, Q 2, R 3, ... W 7, &c., be all equal to A C. Now it is plain that the arcs Q *q*, R *r*, &c., are all greater than A C, and will continue so, however great the radius may be; for A C is the shortest distance which can be drawn from one parallel to the other. But as the radius is extended, the arcs T *t*, V *v*, &c., become *more upright*, as a person unused to geometrical phraseology would say, that is, more and more nearly coincident with a perpendicular drawn from A B; they also become more and more nearly equal to A C. Hence the points 5, 6, 7, &c., come nearer and nearer to C D, with which they would actually coincide, if it were possible that one of the arcs could become equal to A C. Hence the curve, 1, 2, 3, &c., is an asymptote to C D.

The mathematical theory of asymptotes will be found in all works on the theory of curves, and in most on the differential calculus. The following are the most general notions which it will be within our limits to give, and will be understood by a moderately well-informed mathematician. If the equation of a curve be $y=\phi(x)$, and if the function $\phi(x)$ can be separated into two others, say $\psi(x)$ and $\chi(x)$, of which $\chi(x)$ diminishes without limit when x is increased without limit; then the curve whose equation is $y=\psi(x)$ is an asymptote to the curve whose equation is $y=\phi(x)$ or $\psi(x)+\chi(x)$. For the difference of the ordinates of the two curves (to a common value of x) is $\chi(x)$, which diminishes without limit. For instance, let the first curve have the equation

$$y=\frac{b\,x}{x-a}$$

since $\frac{b\,x}{x-a}$ is $b+\frac{ab}{x-a}$, of which $\frac{ab}{x-a}$ decreases without limit when x is increased without limit, it follows that the straight line having the equation $y=b$ is an asymptote to the curve. If the preceding equation be reversed and put under the form

$$x=\frac{ay}{y-b}$$

similar reasoning will show that the straight line whose equation is $x=a$ is also an asymptote. If the first expression be developed in inverse powers of x, giving

$$y=b+\frac{b\,a}{x}+\frac{b\,a^2}{x^2}+\frac{b\,a^3}{x^3}+\&c.$$

the equations of curves which are asymptotes to the preceding may be found by taking any of the preceding terms for y, provided b be always one. Such are

$$y=b+\frac{b\,a}{x}$$

$$y=b+\frac{b\,a^2}{x^2}+\frac{b\,a^3}{x^3}$$

or generally, any curve whose equation is

$$y=b+\chi(x)$$

where $\chi(x)$ diminishes without limit, when x is increased without limit, is an asymptote to the preceding. Observe that a curve may first cut another, then recede from it, and afterwards become an asymptote to it.

The following is a mere sketch of the most general method of finding asymptotes to *algebraical* curves. The first part of the method detects the number and direction of the *rectilinear* asymptotes, those only excepted which are parallel to either axis of co-ordinates, which will easily admit of a separate determination.

Clear the equation of all radicals. Suppose it then of the second degree, though the same reasoning applies to all degrees. Its form will then be (putting all the highest terms on one side)

$$a\,y^2+b\,xy+c\,x^2=dy+e\,x+f.$$

The following theorem can then be demonstrated. If the equation

$$a\,y^2+b\,xy+c\,x^2=0 \qquad \text{(A)}$$

be possible, then it is the collective equation of two lines passing through the origin of co-ordinates, which two lines are parallel to two asymptotes of the curve and the curve can have no others. It is a well-known theorem that any *algebraical* equation between x and y, which is homogeneous with respect to these letters, is not the equation of a curve, but of a collection of straight lines passing through the origin. Thus the asymptotes of the curve of the third degree will be determined by the solution of an equation of the form

$$a\,x^3+b\,x^2y+c\,xy^2+dy^3=0$$

which may belong either to one or three straight lines.

If $y=k\,x+l$ be the equation of an asymptote, the value of k may be any one of the values of $\frac{y}{x}$ determined from the equation (A). To find l, remember that any homogeneous algebraical expression of the mth degree, containing x and y, may be expressed by the form

$$x^m\,\phi\left(\frac{y}{x}\right)$$

and let the equation of the curve, when its various sets of homogeneous terms have been collected, be

$$x^m\,\phi\left(\frac{y}{x}\right)+x^{m-1}\,f\left(\frac{y}{x}\right)+\&c.=0.$$

Then if $\phi'(k)$ represent the differential coefficient of $\phi(k)$, the equation of the asymptote is

$$y=k\,x-\frac{f\,(k)}{\phi'\,(k)}$$

when the highest dimension in the equation exceeds the next highest by more than one, all the asymptotes must pass through the origin of co-ordinates.

The term asymptote is first found in the Conic Sections of Apollonius; and the properties of the hyperbolic asymptote are found in the second book of his Conic Sections.

A'TABEKS are the rulers of several of the small principalities into which the empire of the Seljuk Turks, soon after its establishment, became divided, during the eleventh, twelfth, and thirteenth centuries.

it may be well to mention the 'History of Astronomy,' and the 'Lives of Galileo and Kepler,' in the Library of Useful Knowledge; and the 'History of Natural Philosophy,' in Lardner's' Cabinet Cyclopædia.

ASTY'LAR, one of the numerous compound architectural terms from the Greek *stylos* (στῦλος), column; which, having the Greek privative *a* prefixed to it, signifies without columns. It is a term of recent introduction, but very convenient and expressive, inasmuch as it explains at once that the building described by it is without any order of columns or pilasters, however ornate it may be in all other respects. Thus, we speak of Astylar Italian in contradistinction from the columnar class of buildings in that style, or such as are decorated with the orders. Astylar composition is not only susceptible of a very high degree of embellishment, but of a species of grandeur not attainable (that is, on the same scale) in the Palladian style, or that where an order is raised upon a basement, or even more than a single order is employed for a façade, because in the former the cornice is proportioned to the entire elevation; sometimes of greatly increased proportions, and then distinguished by the name of *cornicione*. In this country we had no examples of such *astylar* class of design, until it was introduced by Mr. Barry, in the Travellers' and Reform Club-houses.

ASY'LUM, the Latin and English form of the Greek Ἄσυλον, which is generally supposed to be made up of *a privative* and the root of the verb συλάω, 'to plunder,' and therefore to signify, properly a place free from robbery or violence. Some, however, have derived the Greek word from the Hebrew אשל, 'a grove;' the earliest asylums, it is said, having been usually groves sacred to certain divinities. It is a pretty, rather than perhaps a very convincing illustration of this etymology, which is afforded by Virgil's expression as to the asylum opened by Romulus,—

> "Hinc lucum ingentem, quem Romulus acer asylum
> Retulit."—Æn. VIII. v. 343.

The tradition was, that Romulus made an asylum of the Palatine Hill preparatory to the building of Rome. Plutarch tells us that he dedicated the place to the god Asylæus. (Plut. 'Romul.' 9.)

Probably all that is meant by these stories is, that in those ages whoever joined a new community received shelter and protection; and even if he had committed any crime, was neither punished by those whose associate he had become, nor surrendered to the vengeance of the laws or customs he had violated. Such an asylum was not an appointed place of refuge established by general consent; it was merely a congregation of outlaws bidding defiance to the institutions of the country in which they had settled, and proclaiming their willingness to receive all who chose to come to them.

But both in the Grecian states, and in Rome, the temples, or at least some of them, were endowed with the privilege of affording protection to all who fled to them, even although they had committed the worst crimes. The practice seems to have been, that they could not be dragged from these sanctuaries; but that, nevertheless, they might be forced to come out, not only by being prevented from receiving food while they remained, but even by such compulsory measures as the application of fire to the building. (See 'Thucyd.' i. 126, 134; 'Herodot.' vi. 80.) Anything appears to have been permitted except the actual dragging forth of the criminal. Eventually, these places of refuge became great nuisances, being, especially among the Greek cities, established in such numbers as sometimes almost to put an end to the administration of justice. After Greece had become a part of the Roman empire, an attempt was made to repress this evil by an order of the senate, directed to all the pretended asylums, to produce legal proofs of the privilege which they claimed. (Tacit. 'Annal.' iii. 60, &c.) Many were put down in consequence of not being able to satisfy this demand. At last, all the asylums throughout the empire were abolished by an edict of the Emperor Tiberius. (Sueton. in 'Vitâ Tiberii.' cap. 37.)

The term Ἄσυλος was given as an epithet to certain divinities; as, for example, to the Ephesian Diana. It is also found on medals as an epithet of certain cities; in which application it probably denoted that the city or district was under the protection of both of two otherwise belligerent powers, and enjoyed accordingly the privileges of neutral ground.

After the decline and fall of Paganism, the privilege of serving as asylums for malefactors was obtained by the Christian temples. The credit of conferring this honour upon churches in general is attributed to Pope Boniface V., in the beginning of the 7th century; but more than two hundred years before, certain sacred buildings of the new religion are said to have been declared asylums by the Emperor Honorius. The asylums thus established eventually grew throughout all Christendom to be a still more intolerable abuse than those of the ancient world had been. In most countries, not only churches and convents, with their precincts, but even the houses of the bishops, came to be at length endowed with the privilege of sanctuary. In all these places the most atrocious malefactors might be found bidding defiance to the civil power. At the same time, there can be no doubt, that while in this way criminals were frequently rescued from justice, protection was also sometimes afforded to the innocent, who would not otherwise have been enabled to escape the oppression or private enmity which pursued them under the perverted forms of law. The institution was one of the many which then existed, having the effect of throwing the regulating power of society into the hands of the clergy, who certainly were, upon the whole, the class in whose hands such a discretion was by far least likely to be abused. When communities, however, assumed a more settled state, and the law became strong with the progress of civilisation, the rights which had at one time armed the church as a useful champion against tyranny, became not only unnecessary but mischievous. The church maintained a long and hard struggle in defence of its old supremacy; and in the face of the stand thus made, and in opposition to ancient habits, and the popular superstition by which they were guarded, it was only very cautiously that attempts could be made to mitigate the evil. For a long time the legal extent of the privilege of sanctuary appears to have been matter of violent dispute between the church and the civil power. In this country, it was not till the year 1487, in the reign of Henry VII., that by a bull of Pope Innocent VIII. it was declared, that if thieves, robbers, and murderers, having taken refuge in sanctuaries, should sally out and commit fresh offences, and then return to their place of shelter, they might be taken out by the king's officers. It was only by an Act of Parliament passed in 1534, after the Reformation, that persons accused of treason were debarred of the privilege of sanctuary. After the complete establishment of the Reformation, however, in the reign of Elizabeth, neither the churches nor sanctuaries of any other description were allowed to become places of refuge for either murderers or other criminals. But various buildings and precincts in and near London, continued for a long time after this to afford shelter to debtors. At length, in 1697, all such sanctuaries, or pretended sanctuaries, were finally suppressed by the Act 8 & 9 Will. III. chap. 26.

In Scotland, the precincts of the palace of Holyrood in Edinburgh still remain a sanctuary for debtors. The boundaries of this privileged place are somewhat extensive, comprehending the whole of what is called "the King's Park," in which is the remarkable hill called "Arthur's Seat." The debtors find lodgings in a short street, the privileged part of which is divided from the remainder by a kennel running across it. Holyrood retains its privilege of sanctuary as being a royal palace; but it is singular as being now the only palace in this country any part of the precincts of which is the property, or at least in the occupation, of private individuals, and therefore open to the public generally.

In England, a legal asylum, or privileged place, is called a sanctuary; and this use of the word sanctuary appears to be peculiar to the English language. Both in this country and in America, the name of asylum is commonly given to benevolent institutions intended to afford shelter neither to criminals nor to debtors, but to some particular description of the merely unfortunate or destitute.

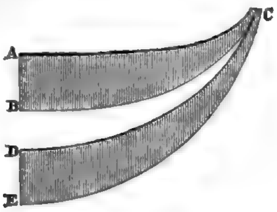
The Jewish Cities of Refuge, established by Moses and Joshua, may be quoted as the most remarkable instance on record of a system of asylum founded and protected by the state itself for the shelter of persons who had violated the law. These cities, as we are informed in the twentieth chapter of the Book of Joshua, were six in number, three on each side of the Jordan. They only, however, protected the person who had killed another unawares. This institution may be regarded as an ingenious device for protecting, on the one hand, the guiltless author of the homicide from the popular resentment, which his unfortunate act would have been likely to draw upon him: and cherishing, on the other, in the public mind, that natural horror at the shedding of human blood, which, in such a state of society, it would have been so dangerous to suffer to be weakened. We see the same principle in the deodand formerly awarded by our law in the case of the accidental destruction of life by any inanimate object.

One of the most curious instances of the privilege of sanctuary, is that long enjoyed in Scotland by the descendants of the celebrated Macduff, Thane of Fife, the dethroner of the usurper Macbeth. It is said to have been granted at the request of the thane by Malcolm III. (Canmore), on his recovery of the crown of his ancestors soon after the middle of the 11th century. By this grant it was declared that any person, being related to the chief of the clan Macduff within the ninth degree, who should have committed homicide without premeditation, should have his punishment remitted for a fine, on flying to Macduff's Cross, which stood near Lindores, in Fifeshire. Although this, however, is the account of the old Scottish historians, it is probable that the privilege only conferred upon the offender a right of being exempted from all other courts of jurisdiction, except that of the Earl of Fife. Sir Walter Scott ('Minstrelsy of the Scottish Border,') has printed a Latin document of A.D. 1291, in which the privilege to this latter extent is pleaded. The original deed still exists. Of Macduff's Cross, only the pedestal now remains, the cross itself having been destroyed at the Reformation. It bore a metrical inscription, in a strange half Latin jargon, the varying copies of which, still preserved, have given much occupation to the antiquaries.

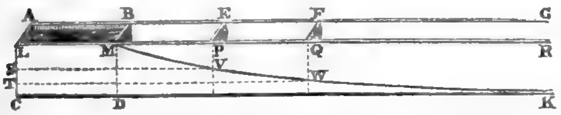
(Sibbald's *History of Fife*, second ed., 8vo, Cupar-Fife, 1802; Cunninghame's *Essay upon Macduff's Cross;* Camden's *Britannia*, by Gough).

A'SYMPTOTE (ἀσύμπτωτος), a compound Greek word signifying *which does not fall with:* if taken literally with respect to two lines, it would mean that they do not meet one another. But it is used only in speaking of two lines (one of which at least must be curved) which continually approach each other, but never meet; so that the distance between them diminishes without limit, or they may be brought to any degree of nearness, without ever actually meeting.

And they also imagine that if two lines might be asymptotic, the fact might be made visible, which is impossible, unless the eye could be made to distin-

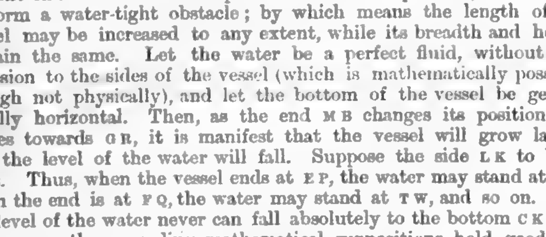


guish any distance, however small. But if the unassisted eye cannot detect a white space between two black lines, unless that space be a thousandth of an inch in breadth, which is about the truth, it is evident that two geometrical surfaces with asymptotic boundaries, such as A B C, D E C, would appear to coincide from the point where the distance between them is about the thousandth part of an inch. The idea of a geometrical asymptote is therefore an effort of pure reason, and the possibility of it must be made manifest to the mind, not to the senses. A L M B C D is a vessel of water, of which the sides and



bottom are extended indefinitely towards G and R; the end A L is fixed, but the end B M is moveable parallel to its first position, so as always to form a water-tight obstacle; by which means the length of the vessel may be increased to any extent, while its breadth and height remain the same. Let the water be a perfect fluid, without any adhesion to the sides of the vessel (which is mathematically possible, though not physically), and let the bottom of the vessel be geometrically horizontal. Then, as the end M B changes its position and moves towards G R, it is manifest that the vessel will grow larger, and the level of the water will fall. Suppose the side L K to be of glass. Thus, when the vessel ends at E P, the water may stand at S V; when the end is at F Q, the water may stand at T W, and so on. But the level of the water never can fall absolutely to the bottom C K; for so long as the preceding mathematical suppositions hold good, and there is some water in the vessel, it must stand at some determinate height above the bottom. As the end B M moves to the right, let the curve M V W, &c., mark out the positions of the level upon the edge of the moving end, as is done in the diagram. Then for the reason above given, this curve never can meet the line C K, though obviously in a state of continual approach towards it. Hence the curve M V W and the line C K are asymptotes.

As another illustration, let there be two parallel lines A B, C D, the perpendicular distance of which is A C; and from A, with different



radii, describe arcs of circles P 1, Q q, R r, S s, &c. From A B on all these circles measure *arcs* equal in length to the *straight line* A C; that is, let P 1, Q 2, R 3, ... W 7, &c., be all equal to A C. Now it is plain that the arcs Q q, R r, &c., are all greater than A C, and will continue so, however great the radius may be; for A C is the shortest distance which can be drawn from one parallel to the other. But as the radius is extended, the arcs T t, V v, &c., become *more upright*, as a person unused to geometrical phraseology would say, that is, more and more nearly coincident with a perpendicular drawn from A B; they also become more and more nearly equal to A C. Hence the points 5, 6, 7, &c., come nearer and nearer to C D, with which they would actually coincide, if it were possible that one of the arcs could become equal to A C. Hence the curve, 1, 2, 3, &c., is an asymptote to C D.

The mathematical theory of asymptotes will be found in all works on the theory of curves, and in most on the differential calculus. The following are the most general notions which it will be within our limits to give, and will be understood by a moderately well-informed mathematician. If the equation of a curve be $y=\phi\,(x)$, and if the function $\phi\,(x)$ can be separated into two others, say $\psi\,(x)$ and $\chi\,(x)$, of which $\chi\,(x)$ diminishes without limit when x is increased without limit; then the curve whose equation is $y=\psi\,(x)$ is an asymptote to the curve whose equation is $y=\phi\,(x)$ or $\psi\,(x)+\chi\,(x)$. For the difference of the ordinates of the two curves (to a common value of x) is $\chi\,(x)$, which diminishes without limit. For instance, let the first curve have the equation

$$y=\frac{b\,x}{x-a}$$

since $\dfrac{b\,x}{x-a}$ is $b+\dfrac{ab}{x-a}$, of which $\dfrac{ab}{x-a}$ decreases without limit when x is increased without limit, it follows that the straight line having the equation $y=b$ is an asymptote to the curve. If the preceding equation be reversed and put under the form

$$x=\frac{ay}{y-b}$$

similar reasoning will show that the straight line whose equation is $x=a$ is also an asymptote. If the first expression be developed in inverse powers of x, giving

$$y=b+\frac{b\,a}{x}+\frac{b\,a^2}{x^2}+\frac{b\,a^3}{x^3}+\&c.$$

the equations of curves which are asymptotes to the preceding may be found by taking any of the preceding terms for y, provided b be always one. Such are

$$y=b+\frac{b\,a}{x}$$

$$y=b+\frac{b\,a^2}{x^2}+\frac{b\,a^3}{x^3}$$

or generally, any curve whose equation is

$$y=b+\chi\,(x)$$

where $\chi\,(x)$ diminishes without limit, when x is increased without limit, is an asymptote to the preceding. Observe that a curve may first cut another, then recede from it, and afterwards become an asymptote to it.

The following is a mere sketch of the most general method of finding asymptotes to *algebraical* curves. The first part of the method detects the number and direction of the *rectilinear* asymptotes, those only excepted which are parallel to either axis of co-ordinates, which will easily admit of a separate determination.

Clear the equation of all radicals. Suppose it then of the second degree, though the same reasoning applies to all degrees. Its form will then be (putting all the highest terms on one side)

$$a\,y^2+b\,xy+c\,x^2=dy+e\,x+f.$$

The following theorem can then be demonstrated. If the equation

$$a\,y^2+b\,xy+c\,x^2=0 \qquad \text{(A)}$$

be possible, then it is the collective equation of two lines passing through the origin of co-ordinates, which two lines are parallel to two asymptotes of the curve and the curve can have no others. It is a well-known theorem that any *algebraical* equation between x and y, which is homogeneous with respect to these letters, is not the equation of a curve, but of a collection of straight lines passing through the origin. Thus the asymptotes of the curve of the third degree will be determined by the solution of an equation of the form

$$a\,x^3+b\,x^2y+c\,xy^2+dy^3=0$$

which may belong either to one or three straight lines.

If $y=k\,x+l$ be the equation of an asymptote, the value of k may be any one of the values of $\frac{y}{x}$ determined from the equation (A). To find l, remember that any homogeneous algebraical expression of the mth degree, containing x and y, may be expressed by the form

$$x^m\,\phi\left(\frac{y}{x}\right)$$

and let the equation of the curve, when its various sets of homogeneous terms have been collected, be

$$x^m\,\phi\left(\frac{y}{x}\right)+x^{m-1}\,f\left(\frac{y}{x}\right)+\&c.=0.$$

Then if $\phi'\,(k)$ represent the differential coefficient of $\phi\,(k)$, the equation of the asymptote is

$$y=k\,x-\frac{f\,(k)}{\phi'\,(k)}$$

when the highest dimension in the equation exceeds the next highest by more than one, all the asymptotes must pass through the origin of co-ordinates.

The term asymptote is first found in the Conic Sections of Apollonius; and the properties of the hyperbolic asymptote are found in the second book of his Conic Sections.

A'TABEKS are the rulers of several of the small principalities into which the empire of the Seljuk Turks, soon after its establishment, became divided, during the eleventh, twelfth, and thirteenth centuries.

The word Atabek is of Turkish origin, and properly signifies 'The Father of the Prince,' or, as Abulfeda explains it ('Ann. Mosl.' t. iii. p. 226, ed. Reiske), 'a faithful Parent.' Four dynasties of Atabeks are particularly noticed in eastern history; those of Syria (and Irak), those of Azerbijan, those of Persia, and those of Laristan: but none of them acquired any historical importance.

ATELLA'NÆ FA'BULÆ, a species of comedy which was common among the people of Campania, and was thence introduced at Rome, where it met with much favour. The name of Atellanæ, or Atellanicæ, was derived from Atella, an ancient town of Campania, now ruined, the site of which is about two miles S.E. of the modern town of Aversa, and near the village of Sant Elpidio. The Atellanæ were also known by the name of 'Ludi Osci,' on account of the name of the people among whom they originated. The Roman writers have transmitted to us a few brief detached traits of the nature of these plays, of which no specimen has reached us. The Atellanæ seem to have somewhat resembled the Greek Satyric drama, with this difference, that, instead of satyrs and other fantastic characters, they had real Oscan characters, or actors, speaking their own dialect, and who were the representatives of some peculiar class or description of people of that country, much in the same manner as the Brighella, Arlecchino, Polecinella, &c., of the modern Italian stage, who are meant as caricatures of the peculiarities of certain classes in their respective provinces, and who speak each his own dialect in all its native humour. Indeed these modern *maschere*, as the Italians call them, may be considered as the descendants of the old Oscan characters in the Atellanæ. One of these Oscan characters was Macchus, a sort of clown or fool. There were others called Buccones, that is, babblers, empty talkers. (Diomedes 'de Grammatica,' lib. i. and iii.) The Atellanæ differed from the *comœdia prætextata*, which represented high characters, as well as from the *tabernaria*, which exhibited vulgar ones; the Atellanæ were a mixture of high and low, pathetic and burlesque, without however degenerating into trivialities or buffoonery. They seem to have been a union of high comedy and its parody. They were also distinct from the performances of the *mimi*, who indulged in scurrilities and in obscene jokes and gestures. (Cicero, 'Epistola ad Papirium.') Macrobius ('Saturn. III.') draws the distinction between the Atellanæ and the mimi; "the latter made use of the Roman language, and not of the Oscan, like the Atellanæ; the performances of the mimi consisted of one act, while the Atellanæ and other comedies had five, with *exodia* (interludes consisting of songs) between the acts; lastly, the mimi had not the accompaniment of the tibicina, nor of vocal music like the others." Valerius Maximus (lib. ii. ch. 4), speaking of the Atellanæ, says, that their jests were tempered by Italian strictness of taste; and Donatus extols their antique natural elegance. Even in their satirical allusions their object was to provoke joyous laughter, rather than excite feelings of hatred or contempt. It would appear that their humour dealt chiefly in ingenious allusions and equivocations clothed in decent words, the meaning of which could only be caught by the better-educated and more refined classes. In their plots they did not aim at any intricate development, or embody an intrigue, but seem rather to have depended on farcical situations, which gave a freer scope to the jointless and satirical dialogue. The Atellanæ were performed by Roman citizens, who were not thereby disgraced, like the common *histriones*, or actors; their names were not erased from the roll of their tribes, and they were not obliged to take off their masks at the will of the audience. In course of time, however, and in the general corruption of morals under the empire, the Atellanæ degenerated; common mercenary players appeared in them, and they became as loose in their language as the performances of the mimi. This may explain the different judgments given of the Atellanæ by different writers. The exodia, or interludes played between the acts of the Atellanæ, are mentioned by Juvenal ('Sat. VI.'), and Suetonius quotes from one of them a line in which Tiberius was alluded to as an old goat; the pun resting on the word *capris*, which means goats as well as the island (Capreæ) noted as the scene of Tiberius's depravity. When Galba entered Rome, an actor in one of the Atellanæ began singing the first line of a familiar tune: 'Venit io Simius a villa,' that is, *the baboon is come to town*, which the audience immediately took up, and continued the song in chorus, repeating the first line as a burthen.

The Atellanæ were written in verse, chiefly iambic, with a frequent recurrence of tribrachs and other trisyllabic feet. Lucius Sylla, the famous dictator, is said to have written Atellanæ. Quintus Novius, who flourished soon after Sylla's abdication, wrote about fifty plays of this kind; the titles of some of them have come down to us; as 'Macchus Exul,' that is, Macchus in Exile; 'Vindemiatores,' or the Vintagers; 'Gallinaria,' or the Poulterer; 'Surdus,' the Deaf Man, &c. Lucius Pomponius of Bononia, who lived about the same time, wrote 'Macchus Miles,' that is, Macchus Soldier, the 'Pseudo Agamemnon,' &c. The Atellanæ afterwards fell into neglect, but were revived by a certain Mummius, mentioned by Macrobius, who however does not state the epoch of the revival. They were, as we have seen, in full vigour under the emperors. (Munk, 'De Fabulis Atellanis,' Lips. 1840.)

A TEMPO, in music, signifies that after any change in motion, by retardation or acceleration, the original movement is to be restored.

ATHAMANTIN ($C_{24}H_{15}O_7$), is a crystalline, fatty body, obtained from the root of *Athamanta oreoselinum*. It contains valerianic acid united to a base called *Oreoselone* ($C_{14}H_5O_3$). Athamantin combines with hydrochloric acid, and the compound, when boiled, deposits crystals of oreoselone combined with water ($C_{14}H_6O_4$), a compound that is isomeric with benzoic acid.

$$\underbrace{C_{24}H_{15}O_7}_{\text{Athamantin.}} = \underbrace{C_{10}H_{10}O_4}_{\text{Valerianic acid.}} + \underbrace{C_{14}H_5O_3.}_{\text{Oreoselone.}}$$

ATHANASIAN CREED, or *Symbolum Athanasianum*, which is also called from the words of its beginning the *Symbolum Quicunque*, is not extant in the works of Athanasius (which contain, vol. i. part i. p. 98, *seq.* another creed, stating the same doctrine, but differently expressed), and is not quoted by contemporary writers; it seems to refer to the later Nestorian and Eutychian controversies—has a Latinised character, or it sounds in Greek like a translation from a Latin original, and appears to contain phrases taken from the writings of Augustine, the bishop of Hippo. Hence we conclude that it was composed about the middle of the 5th century. Some have supposed that Vincentius Lerinensis; others, that Venantius Fortunatus; others again, that Hilarius Arelatensis wrote what is now called the Athanasian creed. According to Paschasius Quesnel, Virgilius of Tapsus, who has been considered to have interpolated the passage, 1 John v. 7, was also the author of the Athanasian creed.

From the 7th century we find that the Athanasian creed has been considered in the western churches to be the most genuine document of the ecclesiastical trinity. It is remarkable that the Athanasian creed was not introduced by the authority of ecclesiastical councils, nor by any external compulsion, but was generally received by the free conviction of the churches that it contained a correct exposition of Christian doctrine, and that it was necessary to give some ecclesiastical definitions of the statements of the New Testament. This important document may illustrate the difference between the solution of an historical question concerning authenticity, and one involving the internal truth of doctrinal contents. (See Cave, 'Historia Litter.,' vol. i. p. 189; Oudin, 'de Scriptor Eccles.,' vol. i. p. 312; Fabricius, 'Biblioth. Gr.,' vol. v. p. 297; Montfauçon, 'Præf. ad Op. Athanasii;' and Schröckh, 'Kirchengesch.' vol. xii. pp. 93–252.) Sherlock has also written on the Athanasian creed. Dr. Waterland supposed it, without much foundation, to have been made by Hilary, bishop of Arles. Hooker ('Eccles. Polity,' B. xlii. c. 11–13) at considerable length defends its use by the Church of England; on the other hand, Archbishop Tillotson said, "The church were well rid of it;" (see Clarke's 'Succession of Sacred Literature,' London, 1830, p. 274.) A defence of the Athanasian creed on physiological principles, by Thomas William Chevalier, Esq., was printed in the 'Morning-Watch,' and published separately, London, 1830. In this dissertation a surgeon refutes the attack of some clergymen.

Before the close of the 6th century, the Athanasian creed had become so well known, that comments were written upon it; it was not, however, then styled the Athanasian Creed, but simply the Catholic Faith. Before the expiration of another century, it had obtained the appellation which it has since preserved. It is supposed to have received the epithet 'Athanasian,' on account of its reference to the subjects of the controversy between the orthodox and the Arians. But Athanasius himself confined his exertions to the establishment of the doctrine of incarnation, and seems not to have insisted much upon the doctrines relative to the Spirit.

This creed was used in France about the year 850; was received in Spain about a hundred years later, and in Germany about the same time. It was both said and sung in England in the 10th century; was commonly used in Italy at the expiration of that century, and at Rome a little later. In the English church it is ordered to be read only on certain feast days.

Many learned men, especially Cardinal Bona, Petavius, Bellarmine, and Rivet, are of opinion that the creed which bears the name of Athanasius was really the production of that bishop. Baronius maintains this opinion, and suggests that it was composed by Athanasius when at Rome, and offered to Julius as a confession of his faith. Bishop Pearson, Dr. Cave, and others, believe that it was not known in the Christian church before the 5th century, and that it was composed by Vigilius, the African bishop. Bingham says, "Whoever was the author, there never was any question made of its orthodoxy, except by the Samosatenians and Arians, in these latter ages of the church." The damnatory clauses have been objected to, but in the Articles of the English church, it is said of the three creeds (the Nicene, Athanasian, and that commonly called the Apostles'), that they "ought thoroughly to be received and believed," adding, however, no anathema; and Jeremy Taylor says, "I am most heartily persuaded of the truth of them, and yet I dare not say all that are not so are irrevocably damned;" an opinion in which other divines of unquestionable orthodoxy coincide.

The controversy on the Athanasian creed has produced in England a great number of works; the most learned and impartial work on this subject is, 'A Critical History of the Athanasian Creed,' by Daniel Waterland, D.D.; the second edition, corrected and improved, Cambridge, 1728.

ATHEISM. [MATERIALISM.]

ATHELING, or ÆTHELING. The indications, in the Saxon period of our history, of anything like the hereditary nobility of the times after the conquest are exceedingly few: certainly, the system which gives to particular families particular names of distinction and particular social privileges, which are to descend in the families as long as the families endure, we owe entirely to the Normans. The Saxons had among them earls, but that word was used to designate, not as in these times only a rank of nobility, to which certain privileges are attached, but a substantial office bringing with it important duties; the superintendent indeed, under the king, of one of the counties or shires, the sheriff, gerefa, in Latin vice-comes, being his inferior, his delegate or deputy. These earls, who were nominated by the sovereign, held their offices as it seems for life, and were usually selected from the most opulent families. Even the sovereignty among the successors of Egbert seems not to have descended uniformly according to our modern principles of hereditary succession.

Yet there were persons in the Saxon times who are spoken of as Æþel-boꞃen, Athel, or Ethel-boren, persons nobly born. The term is used in Luke (xix. 12), in the Anglo-Saxon version of the New Testament, where, in the modern translation, we have the words 'a certain nobleman.' Æthel, Athel, or Ethel, is frequently used by Saxon writers in senses correspondent to those annexed to the Latin word *nobilis*, the English word *noble*, and the German *adel* or *edel*. In the earlier Saxon times there is little doubt the word denoted the free possessor of lands (a member of the Mark or manorial division), in opposition to the noble by service under the king, who were to that extent no longer freemen; "even the Comes," says Mr. Kemble, in his excellent work, 'The Saxons in England,' 1849, "may indeed have become the possessor of land, even of very large tracts, by gift from his prince, but he could not be the possessor of a free hide, and consequently bound to service in the general *fyrd*, or to suit in the folcmot. He might have wealth, and rank, and honour, be powerful and splendid, dignified and influential, but he could not be free; and if the free man so far forgot the inherent dignity of his station as to carry himself (for his *ethel* I think he could not carry) into the service of a prince . . . . can it be doubted that the remunerative service of the chief would outweigh the barren possession of the farmer? . . . . Even if the markmen razed him from their roll, and committed his ethel to a worthier holder, what should he care whom the liberality of his conquering leader could endow with fifty times its worth." As the king's retainers, however, gradually acquired a supremacy over the land-holding freemen, it is probable that the title of nobility which Atheling implied was transferred by degrees from the one to the other.

Polydore Vergil, an Italian, who in the middle of the 16th century wrote a History of England in elegant Latin, falls into the error of mistaking Atheling for a surname, for which he is rebuked by Selden, the author of the admirable work on the various titles of honour which have been in use in the countries of modern Europe. He shows that Edgar Atheling is the same as Edgar the Atheling, or the noble, and that while some of our earlier chroniclers, as Henry of Huntingdon and Matthew Paris, so designate him, others, as Hoveden and Florence, call him Edgarus Clyto. *Clyto* is the Greek term answering to *eminent*, *illustrious*. It is rather a remarkable fact concerning the Saxon kings of England and their families, that they affected titles and denominations of Greek origin, as Clyto, Basileus (king), and Adelphe (sister); the last appears on the seal of the royal abbess of Wilton.

There is no sufficient information to show when the word Atheling first began to be used in the Saxon dynasty, but it has been supposed that it was used from the earliest times by those who could boast of being of the blood of Woden, who was regarded as the common ancestor of all the races of Saxon sovereigns. Some have represented the term as confined to the eldest son of a reigning monarch, or at least to one who was the heir-presumptive to the throne. Sir Francis Palgrave ('Rise and Progress of the English Commonwealth—Anglo-Saxon Period') considers that the heir of the throne received the title of Atheling, but adds, that the heir might be nominated by the reigning king. The Atheling of the Saxons has been by some regarded as equivalent to the term Dauphin in the line of the French monarchy, and Prince of Wales in our own. But this restriction of it seems not to be sanctioned by the passages in Saxon and other early writers in whom it occurs. Cyneheard, an Atheling of Wessex, who had pretensions to the crown, slew king Cynewulf in 786 (Kemble's 'Saxons in England,' 1849).

Nothing is known of any peculiar privileges belonging to the Athelings, as sons of the kings, or members of the royal family. But those who in modern times have had occasion to speak of the term and the circumstances under which it was used, such as Lingard and Turner in their histories of the Saxon period, speak of lands being usually given to the Atheling while still in his minority, probably bestowed to give the ethel dignity. And hence it is that this word Atheling has descended to our times in the local nomenclature of England.

As we have numerous Kingstons, so have we Adlingtons; and both King and Atheling, with slight variations, have descended in union with other local terminations. We have Kingsbury, Kingsley, and Kingswood; Conington, Coniston, Conysthorpe, and Cony-Weston; as we have also Bere-Regis, as it is now called, but by the Saxons, Conybere. So also have we Adling-flete, Edlingham; and no doubt such names of places as Addingham, Addington, and Edington, are of the same etymology. In one instance we have an Edlington at a very short distance from the walls of a castle called Coningsborough—the one the seat of a Saxon Rex or Regulus—the other, no doubt, one of the portions of land which were settled on one of the Athelings.

ATHE'NE, or PALLAS ATHENE, or ATHENA, the Goddess of Wisdom, of Arts, and of Sciences, among the Greeks; known to the Romans as Minerva. The Greeks seem to have included under this name several divinities of a perfectly distinct origin—a goddess of Libya, the daughter of Neptune and of the nymph Tritonis (Herodot. iv. 180), or of Terra, brought forth on the banks of the river Triton in Libya (Diodor. iii. 69); but the one best known to us is the divinity worshipped by the Athenians, and as it would appear, brought from Egypt, at least if we may judge from some of the symbols with which her statue was adorned: she had a sphinx on her helmet and at her feet. Plato ('Timæus,' Opera, vol. iii. p. 21) tells us that she was called Neith by the Egyptians; and Eratosthenes, in his 'Catalogue of the Kings of Thebes' (Euseb. 'Chron.' p. 21), says, that 'Nitocris' may be translated into Greek by 'Athene Nikephoros.'

According to Homer she was the daughter of Zeus; but there is no allusion in either the Iliad or Odyssey to the fable of her having sprung forth completely armed from the brain of that god: it appears, however, in the 'Hymn to Athene,' usually ascribed to Homer. A scholiast on Apollonius ('Argon.' iv. 1310) remarks, that this fable first made its appearance in Stesichorus (who died B.C. 553), and the 'Hymn' therefore must be of a comparatively recent date. In the legend of Hesiod ('Theogon.' 885-889), Jupiter is made to devour his wife Metis, and in process of time Athene is the result of this strange union. She seems to have participated in many of the attributes of her father: she had the power of hurling the thunderbolts of Jupiter, of prolonging the life of man, and of conferring the gift of prophecy. She was a virgin exalted above all feminine weakness. She might be regarded as the opposite in most respects of Aphrodite. In the battle with the giants, she overwhelmed Enceladus with Sicily; she assisted at the building of the ship Argo, and a wooden figure of Athene graced the prow of the vessel; she assisted Hercules; gave the art of prophecy to Tiresias, and immortality to Tydeus, though she afterwards deprived him of it. She was one of the three goddesses who submitted their beauty to the decision of Paris, and she disputed with Neptune the honour of giving name to the new city of Cecrops. The contest was decided in her favour by the production of an olive tree, and the city was hence called Athenæ. (Apollodor. 'Biblioth.' iii. 14.) According to Diodorus (i. 12), the Egyptians gave this name to the goddess of the air, and she was thought to be the daughter of Zeus, because the air is not naturally subject to corruption; and was made to spring from his brain, because air occupies the highest parts of the world. She was called Glaucopis (blue-eyed), because the air is of a bluish colour. The serpent, the owl, and the cock, were sacred to her; and, among plants, the olive. She was worshipped in all parts of Greece, but the most celebrated temple was the Parthenon at Athens, in which there was a chryselephantine statue of colossal size by Phidias.

The statues of the goddess, called Palladia, exhibited her in very ancient times with upraised shield and poised spear, ready to engage

Archaic Head of Athene from the British Museum.

in battle; sometimes, as symbols of her peaceful character, she had in her left hand the spindle and distaff. A stiffly folded peplum was thrown over her chiton (tunic), and she was armed with an immense ægis, which sometimes served as a shield, and sometimes was so contrived as to cover both the breast and back. The outline of the body exhibits none of the fulness of woman in the hips and breasts, while the form of the bones, arms, and back, resembles that of man. Her countenance, at least in the earlier periods of Greek art, was always marked by a serious, almost earnest expression. As far as possible the Greek artist endeavoured to impart sublimity of character to the statues of Athene. But the age of Phidias changed considerably the ancient characteristic marks of the different gods, and from that time Athene was distinguished by her unclouded forehead, her long and well-formed nose, by the somewhat firm compression of the mouth and cheeks, the strongly marked and almost angular chin, the half-closed eyes, and by the hair streaming carelessly over her neck. There are many representations of the goddess in sculpture, on coins, &c., still extant, no public collection of any importance probably being without some. The British Museum contains many fragments of statues of Athene, and numerous representations on Greek vases, coins, and gems. We give an engraving of a very early colossal head of the goddess, now in the first Græco-Roman Saloon, where are also two other busts of Athene: the sockets of the eyes of that here engraved were filled with some different material, locks of hair of some metal were probably also fixed under the helmet, and there were pendants in the ears. A fragment, supposed to belong to the statue of Athene, which was in one of the pediments of the Parthenon, is in the Elgin collection of the British Museum. Numerous examples of all the kinds of statues of Athene are pointed out by Müller in his 'Archäologie der Kunst,' where the subject will be found fully treated.

Minerva, or *Menerva*, was the ancient Italian divinity, known to the Greeks as Pallas Athene. Her attributes corresponded in most respects to those of the Grecian goddess. She was the patroness of arts and industry, such as spinning, weaving, &c., and was the goddess of all the mental powers. Her statue was usually placed in schools; and the pupils were accustomed every year to present their masters with a present called *Minerval*. (Varro, 'De Re Rust.,' iii. 2; compare Tertull., 'De Idol.,' c. 10.) Minerva also presided over olive grounds (Varro, 'De Re Rust.,' i. 1); and goats were not sacrificed to her, according to Varro, because that animal was considered to do peculiar injury to the olive ('De Re Rust.,' i. 2).

There was an annual festival of Minerva celebrated in Rome in the month of March, which was called *Quinquatrus*, because it lasted five days. (Varro, 'De Ling. Lat.,' v. 3; Ovid, 'Fast.,' iii. 809; Gell., ii. 21.) On the first day sacrifices were offered to the goddess, and on the other four there were gladiatorial combats, &c. There was also another festival of Minerva celebrated in June, which was called *Quinquatrus Minores*. (Ovid, 'Fast.,' vi. 651.) There were several temples in Rome sacred to Minerva. Ovid mentions one on the Cælian Hill, in which she was worshipped under the name of Minerva Capta, but the origin of the name is unknown. ('Fast.,' iii. 835-839.) It also appears from several inscriptions, in which she is called Minerva Medica, that this goddess was thought to preside over the healing art.

The etymology of the name of Minerva is doubtful. The first part probably contains the same root min, men, or man, that we have in the Latin me-min-i, men-s, &c., the Greek *μέν-ος*, *μι-μνή-σκω*, &c., and the Sanskrit man-as. Cicero ('De Nat. Deor.,' iii. 24) gives a very curious etymology, "Minerva, quia minuit aut quia minatur;" but some of the ancient grammarians appear to have been nearer the truth in considering it a shortened form of *Meminerva*, since she was the goddess of memory. Festus connects it with the verb *monere*. Müller ('Etr.,' ii. p. 48) supposes that the word is of Etrurian or Sabine origin.

ATHLETÆ (ἀθληταί), were men who contended for the prizes (ἀθλα) given to the victors at the public games of the Greeks and Romans. These games were divided into the light (κουφα), which included running, leaping, and throwing the disc; and the heavy or severe (βαρεα), which consisted of boxing and wrestling, either separately or in combination. In the early periods of Greek history there was little distinction between the agonistæ, or those who practised gymnastic exercises for the sake of improving their health, or for pleasure, and the athletæ, since the public games were open to all. But in course of time the value of the prizes induced men to prepare themselves for the contests by a severe course of training, and it was found that those who did not in fact devote themselves entirely to the practice stood little chance of becoming victors. In the later periods of Greek history the athletæ became, therefore, a distinct class, and private individuals ceased to contend.

The public games formed an important feature in Greek civic polity. Prizes of great value were awarded to the victors, and the victorious athletæ were treated with great honour. A victor at the Olympian, Isthmian, Nemean, and Pythian games, the four great festivals of the Greeks, was honoured by the state to which he belonged with a public triumph. A breach was made in the city walls, through which he entered in a chariot drawn by four white horses, and he was conducted to the temple of the guardian deity, where hymns of victory were chanted. At the public spectacles a seat of honour was assigned to him; he was relieved from the payment of taxes; occasionally his statue was erected in a public place, and in battle he occupied a privileged station.

The training of the athletæ became in course of time a matter of great care, and was conducted with exceeding strictness. Their exercises were conducted by a public officer (the gymnasiarch), in a gymnasium appropriated to the purpose, and known as the *palæstra*; and their diet, to which great importance was attached, was directed by *aliptæ*. Their exercise was prolonged, severe, and continued from day to day; their food, though strictly regulated, was enormous in quantity; and they slept for a long time. In the earlier times the athletæ wore a girdle round the loins ('Iliad,' b. xiii.; Thucyd. i. 6); but later they contended naked. Before the contest they were anointed with oil by the aliptæ; in wrestling they were covered with sand, to allow the combatants to hold each other firmly. Boxing and wrestling were the games which required most strength, and were most admired for the display of manly beauty in the various positions induced during the contest. Wrestling and boxing in combination were known as the *pancratium* (παγκράτιον), the combatants being called pancratistæ. The lighter games were known as the *pentathlon* (πένταθλον, quinquertium among the Romans), and consisted of the five games of running, leaping, throwing the disc, throwing the spear, and wrestling. These were generally played on the same occasion, but sometimes only three of the games were played: the prize of the pentathlon seems to have been adjudged to the victor in the larger number of the games.

Athletæ were very favourite subjects with Greek artists; indeed, there can be little doubt that it was owing to the facilities afforded by the performances of the athletæ for studying the well-developed human form in every variety of position, and exerting itself in energetic action, that the wonderful mastery of the ancient Greek sculptors is largely due. As Müller observes, the statues of athletæ, and the representations of them on rilievi, vases, and gems, enable us to form a tolerably clear idea of the ancient corporeal exercises. From these statues and representations we see that the athletæ were, as a class, remarkable for their well-shaped, robust forms, immense muscular development, powerful limbs, and small heads with crisp curling hair. They are represented in action, in repose, anointing themselves, and indeed in almost every variety of way in which they could be shown in accordance with the conventions of the several branches of art.

Among the Romans, public games were regarded with no less favour than among the Greeks. Athletæ are, however, said to have been first introduced into Rome by M. Fulvius, at the termination of the Ætolian war, B.C. 186. The passion for athletic performances rapidly increased under the emperors, and in the time of Nero large numbers of Greek athletæ were living in Rome. As in Greece, the athletæ enjoyed many privileges, though in Rome they were hirelings. They formed an entirely separate body; were allowed to deliberate on matters connected with their calling; were presided over by one of their own number; lived together, and possessed a common hall. The Roman athletæ must not be confounded with the gladiators, who fought with swords, and whose performances were altogether of a less refined character. There were no gladiators in Greece. [GLADIATORS.]

(Krause, *Gymnastik und Agonistik der Hellenen*; Müller, *Dorians*, iii. § 3, and *Archäologie der Kunst*, § 423; Philipp, *De Pentathlo sive Quinquertio Commentatio*, Berlin, 1827.)

ATLANTES (Ατλαντες), so called by the Greeks, probably, from the well-known fable of Atlas supporting the heavens. This is a term applied to figures or half figures of men used in the place of columns or pilasters, to sustain an entablature; they are called also Telamones, a word of doubtful derivation. Female figures used for the same purpose are called Caryatides. [CARYATIDES.] Though the Egyptians did

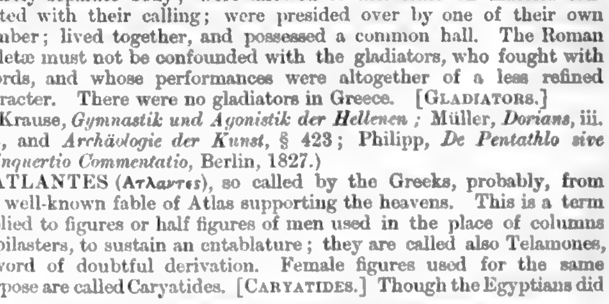


Fig. 1.—From the Temple of Jupiter at Agrigentum.

not use human figures in the place of columns, they used Caryatidic figures attached to the pillars in front of some of their temples, as at Medinet Abou, where the figures are each 24 feet high. Similar figure-pillars occur at Hadjah-Selseleh, and elsewhere. At Denderah, cylindrical columns are surmounted with square capitals, on each side of which is an Isis' head (*Fig.* 2).

There can be little doubt that the Greeks derived the idea of Atlantes and Caryatides from Egypt, but they always used them sparingly. In the temple of Jupiter Olympius, at Agrigentum, restored by Mr. Cockerell, and described in the fourth volume of Stuart's 'Athens,' Atlantes are represented standing upon a plinth placed on the entablature above the pilasters of the cella of the temple, and supporting with their heads and arms the entablature on which the beams of the roof were to have been placed. The Atlantes of this temple were 25 feet high, built in courses of stone, corresponding with the walls of the cella, and partly attached to it. The annexed cut (Fig. 1), showing the front elevation of the figures, with a profile of one of them, has been engraved with the permission of the publishers of Stuart's 'Athens.' (For a

Fig. 2.—Caryatid Pilaster at Medinet Abou.

more detailed account of these figures, see vol. iv. cap. i. of Stuart's 'Athens.')

In the Tepidarium of the baths at Pompeii, Atlantes of baked clay, in high relief, and incrusted with the finest marble stucco, painted to represent life, are ranged at equal distances round the room, to support

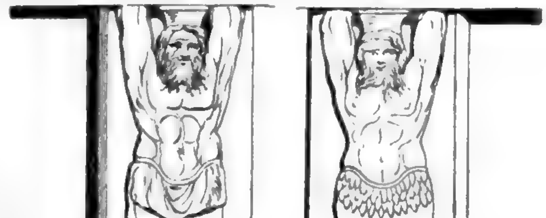

Fig. 3.—From Pompeii.

an entablature from which the arched ceiling springs; in the intervals between the figures, niches are formed for the dress of the bathers. The figures are about two feet high, and stand, like those at Agrigentum, on a plinth; they are represented in Fig. 3.

In the architecture of the modern Italians, the Atlantes are often found supporting the entablature over an entrance to a palace or a garden. At Milan, there is a colossal example of the former; and the rustic gate to the Farnese Gardens at Rome, the design of Vignola, may be adduced as an example of the latter.

The propriety of employing representations of human figures as supporting the entablature or roof of a building, is at least very questionable.

ATLAS, a collection of maps; so called probably in allusion to the mythological figure of Atlas represented as bearing the world upon his shoulders, symbolical of Mount Atlas.

Boucher in his 'Glossary,' says, the word seems to be derived from the German, in which language *atlass* means satin; because a collection of maps was usually made of a smooth satin paper. The word is also now frequently used, and probably for the same reason, for a collection of plates illustrative of a work which is printed on a size much larger than the work itself. It is generally, however, in such cases, distinguished as an Atlas of plates.

ATMOSPHERE (from the Greek ἀτμὸς, and σφαῖρα, *sphere of vapour*), is the whole body of air or other mixture of gases which envelopes a planet. We shall here devote ourselves exclusively to that which surrounds the earth, merely observing, that we have more or less reason to suppose that atmospheres, in density comparable to that of the earth, envelope the Sun, Venus, Mars, Jupiter, and Saturn, but not the Moon.

The subject of the atmosphere, treated in all its extent, would lead us much too far; we shall therefore confine ourselves to the description of its average state. We have already discussed the properties of its constituent materials in the article AIR, and we must further refer as follows, both for subjects which we cannot here enter upon, as well as for extensions of various points which must be incidentally mentioned.

For the general subject of the atmosphere, as connected with the weather, see METEOROLOGY, HYGROMETRY, TEMPERATURE, and articles on particular subjects, such as EVAPORATION, DEW, RAIN, WIND, AURORA BOREALIS, HEAT, ELECTRICITY (ATMOSPHERIC), &c. &c.

For the atmosphere as a medium of communication (taking this word in its widest sense), see ACOUSTICS, AERODYNAMICS, BALLOON, WINDMILL, SAIL. For its effects upon animal and vegetable life, see RESPIRATION, VEGETATION, ANTISEPTICS, DECOMPOSITION. For the effects of the imponderable substances upon it, and *vice versâ*, see HEAT, ELECTRICITY, REFRACTION. For instruments used to measure its state, see BAROMETER, THERMOMETER, MANOMETER, EUDIOMETER, HYGROMETER; and for its uses in the investigation of the elevations of different parts of the earth, see BAROMETER, HEIGHTS (MEASUREMENT OF).

The atmosphere, in its average state, must be considered as a body of air revolving with the earth. This gives its several strata an increasing velocity, as we recede from the earth's axis: and hence, the convex surface of the atmosphere is probably *spheroidal*, and not spherical, since, in the first place, its height would be greater over the equator by reason of its greater centrifugal force, and secondly, by reason of the expansion of the same parts by the greater temperature. Again, at the equator, the air (if any) which is twice as distant from the centre of the earth as the surface, must revolve with twice the actual velocity of the air at the surface. This consideration shows positively that the atmosphere which really accompanies and revolves with the earth cannot certainly extend in the smallest quantity above 26,000 miles from the surface. For at that height the tendency to recede from the centre, known by the name of centrifugal force, would counterbalance the weight, or tendency of particles towards the earth, and at higher distances would overcome it entirely.

But we are not therefore to conclude that there must be air, more or less, *revolving with the earth* up to so great a height. Forty or fifty miles is supposed to be the limit which it attains. Previously, however, to entering upon this question, it is material to know whether we are to consider air as infinitely divisible or not. By which we mean, is it possible for air to be rarefied to any extent whatever, and still preserve its great characteristic, namely, mutual repulsion among its several parts? We might mention various arguments drawn from the ATOMIC THEORY, but Dr. Wollaston ('Phil. Trans.' 1822) has discussed this subject in a form which, while it adds some force to the atomic theory itself, for reasons unconnected with our subject, furnishes a very strong presumption for the finite extent of the atmosphere. The following is a synopsis of his argument:—

If there be air throughout the universe, we are obliged to suppose that every planet would collect an atmosphere around itself, proportionate to its attracting power. In this case, we know that Jupiter, at whose surface the force of gravity must be much greater than at that of our earth, would collect a powerful atmosphere around him. The effect of the refraction of light through this atmosphere would become visible in the approach of the satellites to the planet, when they disappear behind his disc, and would cause a sensible retardation in their rate of approach. No such retardation can be observed in the smallest sensible degree; and, consequently, Jupiter has no such atmosphere, nor the means of collecting it: consequently, air, such as we have at the earth, is not diffused in any degree of rarefaction through the whole solar system. Dr. Wollaston argues that this finite character of the atmosphere is more conformable to the atomic theory than to that of the infinite divisibility of matter, since, in the first case, a boundary is possible, and will exist at the point where the weight of a single atom is as great as the repulsive force of the medium, which has been calculated to be 26,000 miles distant from the earth's equatorial surface; while in the latter case it is difficult to see the possibility of any boundary.

It has been observed, that Encke's comet appears, in successive revolutions, to show in a slight degree the effect of some medium resisting its motion; and the same thing has been said of that of Biela. It might therefore appear that the preceding argument is weakened in force by this circumstance, or *vice versâ*, since the large planets might collect sensible atmospheres of the resisting fluid, whatever it be. But on this we must observe, that supposing the fact of the resisting medium to be established (and several astronomers are of that opinion), it by no means follows that it is common air, or anything approaching to it in the proportion of its density to its elastic power. On the contrary, the facts observed with regard to the motion of the planets (which show no signs whatever of a resisting medium), and the extreme tenuity of the comets themselves (through which very faint stars may be seen), justify us in supposing that the resisting medium may be of a very high degree of elasticity as compared with air; and it is by no means improbable that the planets actually may have atmospheres of this same medium, not sensible to our instruments, on account of the very small increase of density which is sufficient to counterbalance the action of a planet. To elucidate this subject, see Elasticity, Fluid (Elastic).

The preceding arguments go to show, that even supposing the temperature of the atmosphere to be uniform throughout, there is no inconsistency in the supposition of a finite atmosphere. But a very strong presumption in favour of such an hypothesis is derived from the rapid decrease of temperature which takes place as we recede from the surface of the earth. This decrease is conspicuous from the fact that the tops of high mountains are perpetually covered with snow. But the law of decrement is not known with much certainty. According to the latest observations, it would appear that for every 100 yards of ascent, there is an average decrement of 1° F. A slower rate of decrease is evidently given by observations taken during balloon ascents, since it is determined by the barometer, so that they contain the very element in question. Thus, the celebrated ascent of Gay-Lussac at the commencement of this century, gave a decrement of 1° for 316 feet, while Mr. Green and others have made it 485 feet; so that the general average from balloon ascents would seem to be 400 feet, instead of 300. The causes of this decrement are, 1. That, in receding from the earth's surface, we are leaving a heated body, and interposing a badly-conducting medium. Indeed, Fourrier and Pouillet give—226° F. as the temperature of the interplanetary spaces. 2. The heat conducted from the earth is nearly all absorbed by the lower strata of the atmosphere; and 3, Leslie has shown that when air is dragged upwards by masses of rising vapour, it expands, and consequently absorbs caloric; while that which descends contracts, and gives out caloric.

If we take the general law of decrement given above as a basis of calculation (and it is probably nearly correct for heights not exceeding 20,000 feet), we get the following remarkable connection between x, the height in yards, and ϖ, the barometric pressures compared at the higher and lower levels:

$$\varpi = \left(\frac{X}{a}\right)^{5\cdot581}.$$

where $a = 180$ yards $(273 + T)$, T being the centigrade reading at the lower station, and $X = a - x =$ the *depression* of the upper station *below* the height a. "This formula," says Sir John Herschel, in the article Meteorology, in the 'Encyclopædia Britannica,' "makes it very apparent how completely the law of equable decrease is subversive of the received notion of a diminution of pressure in *geometric* progression upwards from the sea-level."

The old theories on the subject of the decrement of temperature as we ascend in the atmosphere may probably be considered as mere hypotheses, and unfounded. Such is that of M. Biot, which assigns a decrement in geometric progression for heights in arithmetic progression, setting out from the assumption that the whole heat of the air at any point is due to the extinction of heat radiated or conducted from the earth to that point.

The argument in favour of the finite extent of the atmosphere, derived from the preceding, is as follows. If we suppose an elevation of 200 yards to produce a fall of 1° of Fahrenheit's thermometer (which, as we have seen, is likely to be below the truth, that is, to give the higher regions of the atmosphere a higher temperature than they really have), it follows, that at a height of forty miles above the level of the sea, the temperature of the air must be 350° of Fahrenheit below that of the sea, or certainly more than 300° below the freezing point. There is the strongest reason to suppose that no gas that we are acquainted with would preserve its gaseous state at this low temperature, but would become liquid: and though no gas has yet been rendered liquid by reduction of temperature alone, yet several have been reduced to that state by cold and pressure united.

If, then, we suppose the atmosphere to be of finite extent, its form (as mentioned above) must be nearly that of an oblate spheroid, the lesser axis passing through the poles of the earth; at the same time the action of the sun and moon must produce certain small *atmospheric tides;* and the tides of the sea, which are constantly disturbing the base on which the atmosphere rests, must produce periodical alterations of form in the latter also. If any such exist, sensibly, they may be detected by the barometer; for, *cæteris paribus*, any increase in the height of the superincumbent column of air must be accompanied by a small increase in the height of the counterbalancing column of mercury. Laplace was the first who examined this curious branch of the subject. He showed by analysis that the attraction of the sun and moon could produce no permanent effect upon the currents of the atmosphere; for instance, such as the trade winds. He also showed that the diurnal oscillations caused by the above-mentioned attractions would only produce a very small effect upon the barometer—in fact, less than one millimetre, or 1·25th of an inch. The reduction of a large number of observations gave, at first, ·055 of a millimetre for the quantity in question; those of another set gave ·018; from which Laplace concluded, taking into account the smallness of the quantities, and the degree of probability which could be attached to results so different, that the *sensible* existence of the atmospheric tide was doubtful. In the meanwhile, however, the diurnal variation of the barometer has been completely established by observations made in several different places. But the law and quantity of this oscillation appears to vary so much with latitude, climate, and other circumstances, that no positive conclusion can yet be drawn, either to the exclusion of atmospheric *tides*, properly so called, or the adoption of any other cause in conjunction with it.

The average pressure of the atmosphere is found to be the same, or very nearly so, at any one place from year to year, notwithstanding the various temporary alterations arising from meteorological causes. But it is not yet accurately determined in a sufficient number of places to settle the question, whether it is the same at the level of the sea throughout the globe or not. Indeed, it is obvious that it must always be difficult to decide whether an observed difference in the mean height of the barometer at two places on land arises from difference of level, or from the atmosphere itself. The mean height of the barometer in London is stated at 29·88 inches; at Paris, where it has been determined with great accuracy, it is 0·760 metres = 29·922 inches. [Barometer.]

As we advance higher in the atmosphere, the barometer falls; and the quantity of the fall is used to ascertain the height ascended. The method of doing this will be explained in the article Heights (Measurement of); we notice it here in order to mention a circumstance which shows that our knowledge of the general conditions of the atmosphere has not been overstated. In order to construct the formula, it is necessary to take into account the diminution of the weight of the air, not only from its rarefaction, but also from its increasing distance from the earth,—the variation of elastic force, as well from rarefaction as from change of temperature,—the alteration of density in the mercury itself, arising from the alteration of temperature,—and to use the formula in different latitudes, the variation of the force of gravity on the earth's surface. In our ignorance of the variation of the temperature, it is usual to allow to the whole column of air contained between the points of observation, the average temperature of its upper and lower extremities. This is the most doubtful part of the process; and as a verification, recourse is had to the comparison of heights measured by the barometer, and also by the processes of trigonometry. It is thus found that a co-efficient which, when deduced from theory alone, is 18337·46, appears from a number of heights measured trigonometrically to be 18336, differing from the former only by about its 18,000th part. This shows the effect of temperature to be sufficiently well taken into account, for such heights as we can measure, by the preceding supposition.

In the article Air some reasons were shown for supposing that its component parts were not united chemically, but only mixed. Now a law is found to prevail in the mixture of gases and vapours, as universal as the one described in the article Air, relative to the expansion arising from temperature—namely, that two gases in a state of mixture exercise no influence one upon the other, except communication of temperature, but that each is disposed in exactly the same manner as it would be if the other were not present. Thus it is found that no pressure of dry air upon water exerts the least influence in preventing the formation of steam, which goes on exactly as if the space above were a vacuum, and continues until further evaporation is stopped by the pressure of the *steam already formed*. It is found that no pressure of one gas can confine another in water; but that supposing a bottle partly full of water, the gas confined in the water will escape to the surface and distribute itself in precisely the same way as if the other gas were not present. By this it is not meant that the action commonly called mechanical cannot take place, or that a stream of hydrogen would not trouble the air; but only that the permanent settlement of one gas is not affected in any way by the presence of another, so long as no *chemical* action is excited. From this principle, Mr. Dalton ('Phil. Trans.' 1826), taking into consideration the presumptions which exist against the *chemical* union of the ingredients of the atmosphere, infers that the atmosphere does not consist altogether of the compound called air, but that the *nitrogen atmosphere* is higher than the *oxygen*

atmosphere. In fact, if there be no chemical union, the above law of the mixture of gases requires us to allow that each is an atmosphere independent of the other, and that the two are most probably of unequal heights. From some considerations, into which we cannot here enter, Mr. Dalton thinks that the actual pressures exerted by the oxygen and nitrogen are in the proportions of the *volumes* occupied by them [AIR], that is as 1 to 4; and concludes that the *oxygen atmosphere* extends to 38 miles in height, that of nitrogen to 54 miles, that of carbonic acid to 10 miles, and that of aqueous vapour to 50 miles. It must however be observed, that the state of the carbonic acid of the atmosphere is very variable; that there is not the same quantity by night as by day, in moist weather as in dry; and that the higher strata of the atmosphere contain more of it than the lower, which may arise from rapid absorption by the earth. This was observed by M. Saussure in his ascent of Mont Blanc, who mentions the large quantity of carbonic acid at that height, which, with the rarity of the air, produced in him hæmoptysis from the lungs.

Against the hypothesis just described, it might be asserted that the air which Gay-Lussac brought down from a height of more than four miles was not found to differ from that of the earth's surface in the proportion of its oxygen to its nitrogen, which would be the case if the oxygen atmosphere diminished in density more than in proportion to the diminution of that of the nitrogen, or *vice versâ.* We do not know whether the experiment of M. Gay-Lussac was made, or even intended to be made, with that degree of accuracy which would justify its being considered a test of Mr. Dalton's theory; but in any case it is an experiment which it was very desirable to repeat. Accordingly, in the balloon ascents undertaken by Mr. Welsh and Mr. Green, under the direction of the Kew Committee of the British Association, specimens of air were collected at different elevations. A portion of air collected in August, 1852, at an elevation of 18,000 feet, was analysed by Professor Miller of King's College, and found to contain 20·88 per cent. of oxygen by volume, while air collected at the same time at the surface of the earth contained 20·92, a difference too slight to be of any importance. Indeed, the results obtained by Regnault, Brunner, Verver, and others, on air collected at different points of the earth's surface, and subjected to different methods of analysis, do not vary more than $\frac{1}{500}$th from the quantity of oxygen given by Dumas and Boussingault as the result of numerous careful analyses, namely, 20·81 per cent. of oxygen per measure, and 79·19 of nitrogen, or by weight, 23·01 of oxygen and 76·99 of nitrogen.

The weight of the whole atmosphere is calculated thus:—The weight of a column of it having a base = 1 sq. inch, is 14·7304 lbs.; hence, taking the diameter of the earth = 7926 miles, we easily find the weight of the atmosphere = 11·67085 trillions of pounds, which is about $\frac{1}{1550000000}$th part of the mass of the earth itself.

The specific gravity of dry air is to that of mercury as 1 : 10513½, and a cubic foot of it weighs 1·29 ounces; hence, were the air of uniform density throughout its mass, in order to exert the same pressure, it must be 26214 feet, or about 5 miles in height. This is what is called the *height of a homogeneous atmosphere.*

We mentioned, under article AIR, that the average pressure on the human body is nearly 15 tons. Now, since at one time, the barometer in this country stands at about 31 inches, at another time at only 28 inches, it will be seen on calculation, that this will cause a difference in pressure on the body of as much as 1½ tons at different times. The reason why we do not feel this change of pressure is, that when, in very fine weather, the barometer stands at 31°, the tone of the system is strengthened, and we are more lively and active; while in damp muggy weather, on the other hand, we become sensible of listlessness and inactivity. All the while too, the external and internal pressure become very soon equalised, and the animal juices which in the one case are secreted with increased energy, in the other are but moderately produced.

For the colour of the atmosphere, see AIR and SKY. For the quantity of moisture contained in it, see HYGROMETRY.

For the history of atmospherical researches, see the following names in BIOG. DIV., HERO, CTESIBIUS, GALILEO, TORRICELLI, PASCAL, BOYLE, MARIOTTE, PRIESTLEY, SCHEELE, BLACK, LAVOISIER, CAVENDISH, &c.

The actual constitution of the atmosphere, whether composed of molecules exerting a repulsive force upon each other or not, must remain unsettled until some mathematical hypothesis can be found which shall satisfy all observed phenomena. That probabilities are at present all on the side of the molecular or atomic hypothesis, is pretty generally admitted; and the repulsion of the several parts of air is a fact of every-day experience. Newton entered upon this question, and showed ('Principia,' book ii. prop. 23) that if the constitution of the atmosphere be atomic, and if the force exerted by each particle extend only to those nearest to it, and be either nothing or inconsiderable as to all others, that then the observed proportionality of the elastic force to the density is consistent with no hypothesis except that of a repulsive force inversely proportional to the distances of the particles from each other; that is, which becomes double when the distance is halved, and so on. But in the scholium to the same proposition, he takes notice of the imperfection of the hypothesis, and describes his theory as a mathematical 'handle' to induce philosophers to consider the subject further. The molecular theory, on the supposition that every particle repels all the rest, or, which is as likely to be the case, has alternate spheres of attraction and repulsion, is beyond the reach of the present state of mathematical analysis.

ATMOSPHERIC AIR, a distinction which has been preserved after the necessity for it has ceased. In the time of Priestley all gases were called *airs,* and common air was called *atmospheric* to distinguish it from other gases. It is sufficient simply to refer to the word AIR.

ATMOSPHERIC INFLUENCE. In the following remarks it is proposed to confine attention exclusively to the action of the atmosphere upon the materials usually employed in the arts of construction. All organic bodies are no doubt affected, in a greater or less degree, by the same influences which affect building materials; but the mysterious power of life so distinctly modifies the action of the laws of mere inorganic matter, that a sufficiently broad line of demarcation may be observed between the chemistry of organic and inorganic bodies, to justify the exclusive investigation of the action of the atmosphere on inorganic matter in this place. Moreover, the striking circumstances under which many of our recently erected public buildings have decayed, and many valuable works of art have been lost, has of late years attracted so much attention as to require more than a passing notice.

The atmosphere affects the materials used in the arts chemically and mechanically; and at the same time it acts as the medium through which moisture, heat, electricity, and other natural powers are able to attack the elements of which those materials are composed.

The chemical decompositions determined by the influence of atmospheric agents, depend of course, upon the composition of the atmosphere itself; and this is known to vary in an extraordinary manner in different localities. The normal composition of air is considered to be of 208 parts of oxygen to 792 of nitrogen, but there are also numerous other gases present in it, such as carbonic acid, ammoniacal, hydrochloric, nitric, sulphuric, and sulphuretted hydrogen, the proportions of all which are affected by local causes in every imaginable manner. Thus the quantity of carbonic acid gas has been ascertained to vary within the range of from 3 to 6 parts (in volume) in 10,000; the amount of ammonia taken up by rain water in falling through the atmosphere, is said to vary notably with the position in which the observations are made, within a range of from 1 to 5·45, even according to M. Boussingault. The atmosphere of the large towns of England especially, contains large quantities of sulphuric acid arising from the combustion of coal, and according to Dr. Angus Smith, its amount may occasionally attain to as much as ·0042 per cent. in weight of the atmosphere. In Paris, the acetate and hydrosulphate of ammonia replace the sulphuric acid of English cities; and on the sea shores hydrochloric acid may be very distinctly traced, in consequence of the evaporation from the sea water.

The meteorological conditions of the atmosphere also are subject to periodical variations; but these are, generally speaking, of great regularity. Thus the electrical state of the atmosphere attains, in clear weather, two maxima and minima, in the course of the day; the first maximum occurring between 7 and 9 A.M.; and the second, between 7 and 9 P.M.; but of course, the hygrometric state of the air must interfere with this phenomenon. The intensity of the sun's light, and, as a necessary consequence, its actinic power, attains its maximum rather before midday; and its minima, a few minutes before, and after the termination or commencement of twilight. Upon the average of the year, the maximum of the daily temperature occurs about 2 P.M.; whilst the minimum appears to exist when the sun occupies a position of about 14° 47′ below the horizon in the morning. The atmosphere is driest about midday, and it contains the greatest amount of moisture by night: but the deposition of dew takes place with the greatest copiousness between midnight and sunrise, on account of the cold then prevailing. In our latitudes the horary differences in the barometric pressure are hardly perceptible; but it would appear that there is a normal tendency to produce a rise of the barometer in the morning, and that the mercury falls about midday, to rise again about sunset, and to fall again at midnight. These facts lead to the inference that the meteorological fluctuations of every day are affected by the relative positions of the sun and earth; and that they correspond, more or less closely, with the cardinal positions of the former at its rising and setting, at midday and midnight.

The rate of evaporation, and the amount of humidity in the atmosphere are amongst the most important conditions of its action; and it is to be observed, that the intensity of their respective actions is the greatest at directly opposite seasons of the year; for evaporation takes place to the greatest extent during the summer months, and is the least apparent in winter, whilst the amount of humidity in the atmosphere is greatest in winter and least in summer. It thus happens that the greatest amount of moisture is in suspension in the atmosphere, in a state to be absorbed by porous materials, precisely at the season of diminished temperature and exposure to the attacks of frost; and again, evaporation takes place at the period when the conditions of temperature are such as are most favourable to the production and development of the salts generated by the previously absorbed moisture acting upon the earthy bases.

The various external agents above noticed produce their destructive effects upon materials used in the arts, either by the new combinations they superinduce between the earthy bases, the metals, and the metalloids; or by the solution and removal of the combinations previously existing. Under some conditions, however, the very same agents which are occasionally so injurious, may produce advantageous results; and as they thus act to consolidate as well as to destroy, the study of their mode of action becomes one of great interest and importance to the architect and builder especially. Strange to say, nothing of any scientific value is known upon the subject; and there is upon record nothing beyond a few empirical observations, to guide the student in his inquiries. The following brief remarks will, it is believed, be found to contain all that is known with respect to the changes produced by the atmosphere upon the various descriptions of materials enumerated. The choice of those materials has been made distinctly on account of their frequent use in the arts of construction.

Granites, which are usually considered to be amongst the most durable of building materials, present nevertheless many varieties differing greatly in their composition, and the mechanical arrangement of their elements; and consequently also in their durability. Thus the granites from Devonshire and Cornwall often contain a large proportion of schorl, and they are frequently pervaded by masses of felspar, of such dimensions and so distinctly crystallised as to cause the mass to assume a porphyritic character. According to Sir H. de la Beche, the granites of Ireland are of the same character, but the schorl occurs in smaller proportions; whilst the granites of Aberdeen are more decidedly micaceous, and schorl is rarely found in them. The Aberdeen granites also differ from those of the west of England and Ireland in their mechanical structure, as they have their component parts more equal in volume and more evenly distributed. In some cases hornblende takes the place of mica; and in others, the quartz and felspar are so much affected in colour, by the presence doubtlessly of the hydrous oxide of iron, as to assume a general rosy hue, as in the case of the Peterhead granites, and the red Egyptian porphyries. The granites of Guernsey, Jersey, and of the French coast, as well as those of the north-western parts of Spain are very similar in their composition to those of Cornwall; and the decomposition of the excess of felspar they contain, gives rise to the large deposits of kaolin clay to be found in some of those respective localities.

Sir H. Davy ('Agr. Chem.,' p. 189) explains the mode of decomposition of granites as follows: "The quartz in them is almost pure silicious earth in a crystalline form. The felspar and mica are very compounded substances; both contain silica, alumina, and oxide of iron. In the felspar there is usually lime and potassa; in the mica, lime and magnesia. When a granitic rock of this kind has been long exposed to the influence of air and water, the lime and the potassa contained in its constituent parts, are acted upon by water and carbonic acid; and the oxide of iron, which is almost always in its least oxidised state, or in that of the protoxide, tends to combine with more oxygen: the consequence is, that the felspar decomposes, and likewise the mica, but the first the more rapidly." There does not appear to be any reason to question the correctness of this explanation, and indeed it is still received as being the true mode of accounting for the decay of granite; but there appear to be different conditions in the combinations of the bases of felspar, which give rise to some apparent anomalies. Thus, the Egyptian porphyries, which contain a notable excess of rose-coloured felspar, resist the influence of the atmosphere in an extraordinary manner. Possibly this may be accounted for by the closeness of the grain (so to speak), which would to a certain extent prevent atmospheric moisture from communicating with anything beyond the immediate surface; or the more simple character of some of these porphyritic rocks may be favourable to their preservation; whereas the different rates of expansion of the ingredients must have a material mechanical influence in disintegrating rocks when they exist in considerable numbers. The difference between the rapid rate of decomposition of the porphyritic granites of Spain, Brittany, and Cornwall, and that of the Egyptian specimens, appears to justify the inference that the cause last suggested has great influence upon their durability. The former are, in fact, composed of a greater number of ingredients than the latter, in which both mica and hornblende are wanting. Practically it is found that the uniform character of the Aberdeen granites resists atmospheric influences in our latitude better than the more easily worked stones of Devonshire and Cornwall.

Whinstones, or basalts, become disintegrated unequally under the effects of exposure to the atmosphere, in consequence of the variable proportions of felspar they contain, and perhaps also of the particular combinations of alumina, lime, and magnesia, which, in connection with silica, constitute their base. If any potassa be present in combination with the silica in the shape of felspar, the action is more rapid than under ordinary circumstances, the humidity of the atmosphere decomposing the felspar into two substances, one of which is soluble, and easily removed by succeeding rains. Serpentines, and the diallage rocks, which are silicates of magnesia combined with hydrates of that base, yield easily to the attacks of acids when the silicates are in certain proportions and alumina is present. The most beautiful varieties of these materials employed in the arts are obtained from the environs of Genoa, and from Zœblitz in Saxony; but it is much to be feared that the atmosphere of large towns, especially when containing sulphuric acid gas from the combustion of coal, renders the employment of even the best of these decorative materials very hazardous. It appears also that in parting with their water of crystallisation upon exposure to the air, an unequal construction takes place in the constituent parts of the serpentine obtained in certain localities, which in consequence breaks in an irregular manner.

The next description of building materials to be considered, in following the ascending order of the geological series, are the slate rocks. Those worked for the supply of the London market are principally situated in North Wales, Cumberland and Westmoreland, the former being a tolerably homogeneous clay slate, the latter being much more chloritic. Exposed freely to the action of the atmosphere, both varieties appear to be tolerably durable, but Westmoreland slates decay very rapidly in damp positions, when the air around them is not frequently renewed. They decay, in fact, in the covered parts, probably from the decomposition of the silicate of iron to which they owe their peculiar colour. The combination of silica and alumina in the Welsh slates appears to be more stable than that which prevails in any other material of the same nature; for their powers of resistance to atmospheric influence are greater than those of any slates employed in Western Europe or North America. As a general rule, the denser the slate the more durable it will be; and the most important condition to be observed in its use is, that water should not be allowed to percolate between the edges of the strata. Practically, it is found that the smoother the surfaces of the slates, and the closer they lie, the greater is the pitch requisite to be given to the roof; because, under such circumstances, capillary action takes effect to a greater extent than when the slates present irregular and perceptibly large intervals.

The various sandstones, millstone grits, and conglomerates are affected by the atmosphere, either through the decomposition of the material cementing their particles together, or by the mechanical effects of moisture. These last may consist either in the removal of the cementing material, or in the destruction of the cohesion of the particles by the expansion of the water in freezing. Many of the sandstones occur in regular layers, separated by thin films of a species of clay, as in the common Yorkshire flagstones; and when these films are sufficiently thick to offer an efficient resistance to the passage of water, to retain it in fact under the upper shale, the expansion during frost will almost inevitably detroy the stone. If the water should change its form from other causes, such as heat, the same effect will be produced; and it is therefore found that the Yorkshire stones of a very porous, and at the same time of a very fissile character, are unable to resist the extremes either of cold or heat.

The best materials of this description are those of an homogeneous nature, such as the Park Spring, the Idle, and the Darley Dale stones, in all of which the minute subdivisions appear, and the mass may be described as consisting of an assemblage of distinct molecules of similar nature, united by mechanical juxtaposition. The sandstones, in which the silicious molecules are united by a calcareous cement, are however far more susceptible of decomposition than those united by a silicious cement; for it appears that in the former cases the chemical combination is rarely effected between the lime and the silica, as the latter is not in the state known as free silica, nor such as can easily form combinations with other materials. In the case of some of the millstone grits, however, the cementing substance, which is silicious, forms so energetic a combination with the molecules it envelopes, that both resist the action of external causes in an equal manner, and the durability of the Bramley Fall stone may fairly be compared even to that of granite itself. These remarks may be extended to the conglomerates, in all essential respects at least; because in fact, generally speaking, they differ from the millstone grits only in the size of their elements.

The crystalline marbles vary in such a very marked manner, both in the nature and the proportion of some of their constituents, and they have been so modified by the accidental circumstances of their geological position, that it is more than usually difficult to trace the laws of their decomposition under the action of atmospheric causes. In many instances they are traversed by veins filled in with more perfectly defined crystals of the base of the rock, or the fissures caused by these veins are filled in with extraneous matters, such as clay, and sometimes even with minerals. Again, however regular the structure of the mass may seem, there is always a tendency in the more crystalline rocks to assume a distinct cleavage, which is often different from the direction of the planes of stratification. Under such circumstances, the moisture furnished by the atmosphere either furnishes the elements necessary for the decomposition of the materials introduced into the veins, or by the mechanical effects it produces in consequence of the changes of temperature, disintegrates the mass. The former class of phenomena may be most distinctly observed in the Breccias, or such marbles as the Brocatello and the Oriental Jasper; the white marbles very frequently exhibit the cleavage above alluded to, and are the most exposed to the injuries produced by the infiltration of water between the planes of division. It is to be observed, that the species of false stratification indicated by the cleavage is most apparent in the rocks which, like the slate rocks, have been affected by proximity to igneous formations, and that the more crystalline the marble the more exposed it is to this inconvenience. At the same time, it must be observed, that the more perfectly crystallised carbonates of lime, under which denomination in fact nearly all the finer marbles may be included, resist the chemical influences of the atmosphere more successfully than similar substances where the forms are not so distinctly marked. It would appear as though the process of crystallisation were accompanied by the development of some chemical affinity between the ultimate particles, similar to that which is noticed with respect to the various forms of silica, and which enables them afterwards to resist more energetically external causes of decay. In some marbles the joints assume different directions from either the lines of stratigraphical deposition, or from the planes of cleavage; but in the practical operations of building the consideration of this peculiarity may be neglected, because they are usually so distinctly marked as to place in reality the natural limits to the sizes of the blocks raised.

M. Durocher communicated to the Académie des Sciences a memoir "sur l'absorption de l'eau atmospherique par les substances minérales," which throws some light on the subject of the decomposition of silicated materials, or those containing metallic oxides. From his experiments it appears that all substances of this description actually absorb water from the atmosphere, and undergo a commencement of hydration, which must necessarily facilitate the decomposition of mixed minerals, such as the silicates, and is apparently the commencement of that action. Messrs. Jamin and Bertrand have also shown that in porous bodies gases are condensed with remarkable facility, so that it is possible that the conditions of molecular aggregation influence the durability of mineral substances in the direct proportion of the facilities which are offered to the passage of air to the interior. From this we may infer that the existence of a crystalline structure is in itself a protection to the materials in which it may occur, because under such circumstances the porosity is usually less; or at any rate, the intervals between the ultimate molecules are proportionately smaller than in the case of materials held together simply by aggregation without crystallisation. Sir H. de la Beche notices the universality of this law ('Geol. Observer,' ed. 1851, p. 8), but he does not attempt to account for it.

The magnesian, the oolitic, and the ordinary secondary and tertiary limestones are liable to decay under the influence of the atmosphere with very various degrees of rapidity; and it is moreover to be noted, that the same formations yield materials varying singularly in their powers of resistance according to the position they occupied in the quarries, and the exposure of the building in which they are employed. The results obtained by the use of the Anston magnesian limestone, and the marked differences to be observed in the Bath, Caen, and Portland oolites, as well as in the several members of the tertiary series of the Paris basin, appear to show that no *à priori* laws can be laid down with respect to their durability when exposed to the air. All these classes of materials are supposed to have been deposited by waters containing their elements in solution; and if they were once in that state (that is, of solution), it must be evident that they are always susceptible of passing into it again if the necessary conditions are presented, unless the deposition should have been effected by the introduction of some additional element, or such element should have been supplied at a later period. There is another chemical agent at work in many cases to hasten the decomposition of the sedimentary rocks unaffected by Plutonic action, namely, the animal matter which they so often contain; and as the distribution of this matter is not subject to any definite law, it necessarily produces irregular effects. Occasionally, also, the body of the stones is traversed by numerous fissures, which have been subsequently filled in by more crystalline materials of greater powers of resistance; and again, the chemical nature of these stones often varies, owing to the presence of more or less silica in combination with the ordinary bases. Every possible variety in the mode of disintegration may therefore be observed in these stones.

Experience has shown that the magnesian limestones are not more capable of resisting the effects of our London atmosphere than the carbonates of lime formerly used, when proper care has been exercised in the selection of the latter. Mr. Rogers indeed remarks ('Brit. Assoc.' 1849), that rain water slightly carbonated takes up the carbonate of magnesia more rapidly than it does the carbonate of lime, and that the magnesian silicates are easily soluble even in pure water. Forchhammer also observes, that water which contains carbonate of soda acts easily upon magnesian rocks. Now, it is very probable that the rain water falling through the atmosphere of London may become charged at any rate with carbonic acid gas, and thus be rendered extremely prejudicial to this class of materials; and it is possible that the rain may give rise to a catalytic action between the lime and magnesia contained in this class of stones, which would facilitate their decomposition. Every stone, as may be gathered from what has been said above, is exposed to decay in the precise ratio of its porosity, but in addition to this cause of disintegration, which acts principally by allowing water to exercise its natural mechanical powers, all the ordinary building stones are exposed to the peculiar process known by the name of nitrification, which, in consequence of the formation of the crystals of nitre, combined with a base, tends to disintegration of the surface. The magnesian limestones allow the development of this process as freely as the carbonates of lime, even if they do not offer extraordinary facilities for its action. The generally received opinion is, that the azote, furnished by the decomposition of the animal matters diffused through the rocks, combines with the oxygen of the atmosphere to form nitrogen, which latter gas in its turn combines with the soda, existing in small quantities in all sedimentary deposits, to form the nitrate of soda. Dumas says that azote and oxygen combine most readily under the influence of electricity, but that the energetic bases, lime and magnesia, may suffice, especially when moisture is present, to replace that intermediate agent. At any rate, this chemical operation takes place in nearly all building stones of a porous nature, and it may confirm the common opinion that of stones of the same description geologically, the densest are the most likely to resist the action of the atmosphere.

Of late years attempts have been made to cast doubts upon the correctness of the generally received opinion, that it is essential to place stones on the same bed as they occupied in the quarry. With some few stones when in place, it may be true that the position of the layers is a matter of indifference; for the roche de St. Cloud, and the Villebois stone of the neighbourhood of Lyon, amongst the secondary and tertiary limestones, have been employed without reference to the planes of bed for many centuries without inconvenience. But these cases are decidedly exceptional, and even in them the powers of the stone to resist a crushing weight are less when it is applied in a direction parallel to the beds, than when it is applied transversely. In almost every other case it will be found that when stones are used the wrong way of the bed, to employ a workman's phrase, they disintegrate in parallel plates. Great care requires to be exercised to ascertain the precise direction of the natural beds, because many stones present the appearance of inclined planes of deposition, which cut the beds and joints under every modification of angle. When from the stones having been worked in the quarry it is difficult to ascertain the precise bed, it is possible that the mason may be misled by the greater facility with which they work in one direction, and may mistake this cleavage for the real bed. The only remedy appears to be to cause the stones exposed to this danger to be marked in the quarry, but fortunately the examples of its occurrence are rare.

The principal danger of exfoliation arises from the expansion of the moisture contained in the stone under the influence of frost, and a very elegant process was invented by M. Brard, for the purpose of ascertaining the probable extent due to this cause. M. Brard in his experiments upon the resistance of stones, caused them to be boiled for half an hour in a saturated solution of the sulphate of soda. They were then withdrawn and allowed to stand in a flat vessel, at the bottom of which was a small quantity of the same solution, the first efflorescences were washed off, and the degradation of the stones during the next five or six days, under the effects of the continued efflorescence, was taken as an indication of the probable extent to which they would be affected by frost. In the first volume of Rondelet's 'Art de Bâtir,' p. 307 (ed. 1842, Paris), M. Brard's process is described in detail; but some very curious experiments recorded in vol. vii. première série des 'Annales des Ponts et Chaussées,' by M. Minard, together with an article by M. Vicat, inserted in the same volume, throw very considerable doubts upon the exact amount of dependence to be placed on its indications. M. Vicat, indeed, very properly observes, that it still remains to be proved that the expansive action of water in freezing is identical with that of crystallisation, which can only produce energetic effect at temperatures between 68° and 86° Fahr. According to this very accurate observer, stones which are exposed to a southerly aspect on the north of the equator, are more affected by frost than those exposed to the north; and the most efficient protection to materials of this description of a porous nature is a coating of oil paint, or any other fatty pigment which prevents moisture from being driven or absorbed into the stone. M. Minard recommends that stone should be quarried in the spring, and not employed in a building until it has been exposed to the effects of one winter at least.

In many varieties of the oolites, the fossil shells are to be observed left in high relief upon the surface by the decomposition of the materials in which they were embedded, and in Bath stone the veins of calcareous spar frequently become detached. It appears that the cause is the same in both cases, and that the shells and the veins protrude in consequence of the resisting powers of the more perfectly crystallised carbonate of lime, of which they are composed, exceeding those of the amorphous mass in which they are embedded. When nodules of flint or chert occur in the numerous varieties of carbonate of lime, the stone around them is usually more durable than the general mass of the rock, doubtless because it contains a portion of the silica in combination with the lime. It is known, indeed, that the application of a soluble solution of silica will at all times add much to the durability of the purer carbonates of lime; but it is very desirable that the conditions under which such a solution should be employed, should be made the subject of close and careful experiments. The application of Kuhlman and Ransome's processes for the preservation of stone, may hereafter throw light upon this obscure branch of practical chemistry.

With respect to the gypseous formations, it appears that where they occur in sufficient abundance to be used as ordinary building materials, they absorb moisture from the atmosphere with extraordinary facility; while they decompose with such rapidity that the municipal authorities of Paris have forbidden their being used for the walls of houses. Occasionally, however, rubble plaster stone is used for inclosure walls, but it rarely lasts more than from twenty to thirty years, when exposed to the weather near Paris. The cause of this rapid decay, according to Gmelin, is to be found in the fact that the sulphates with an earthy base (gypsum being a sulphate of lime), are soluble in water. It is also to be observed that many of the gypseous deposits, especially those found near Paris, are impregnated with an extraordinary proportion of organic matter; this decomposes on exposure to the air in warm and damp positions, and gives rise to the formation of nitrous salts to such an extent, that the saltpetre used by the French powder manufacturers, during the last war, was almost entirely obtained from cellars constructed of rubble masonry, set in plaster in the style usually adopted in France. It is possible that the gases which are present in rain water, or in the atmosphere, may give rise to a species of decomposition by relative affinity, in combination with the sulphuric acid of the gypsum.

Atmospheric influence upon bricks, tiles, and other building materials obtained by the burning of plastic clays, depends very much on the chemical composition of the clays and on the degree of burning. Thus any distinct portions of limestone present in them would be converted into quick lime in the kiln, and when the bricks were thoroughly wetted, would expand in such a manner as to disintegrate the mass. If the clay used be too poor, that is to say, if it contain an excess of sand, the bricks will not become sufficiently fused, and upon exposure to the weather their constituent parts will separate. It is to be observed that in bricks, as in stones, decomposition does not take place with the greatest rapidity where constant moisture exists, but rather where, from the influence of capillarity, variable according to the moisture furnished by the atmosphere either directly or indirectly, a series of alternations of dryness and humidity prevail. The foundation walls of buildings do not in fact suffer so much in the parts immediately upon the ground, as they do in those at a height of from one to three feet, according to the permeability of the materials employed. When bricks made of clay containing free silica are laid in mortar, and moisture can pass freely from either one or the other, it may be observed that the edges in contact become harder than the body of the bricks. No doubt this arises from the formation of a silicate of lime and alumina, the lime being furnished by the passage of the water through the bed of mortar.

Upon limes and cements the effects of the atmosphere are very marked, although at present they are considered to be of far less importance than formerly. All the materials of this class, whether the hydraulic or the rich limes, the cements or the plasters properly so called, have a remarkable avidity for water, and abstracting it from the surrounding atmosphere assume the form of hydrates. If these occur in the conditions requisite to enable them to pass into the carbonates or sulphates, a species of confused crystallisation, or aggregation, takes place. But it must be evident, from what was said in the commencement of this notice, that the quantity of carbonic acid gas the atmosphere is capable of furnishing within a moderate period is exceedingly small, and the theory that limes or cements harden originally by the absorption of that gas, and the consequent conversion of the lime into carbonate of lime, must be abandoned. There can be no doubt but that the conversion of the lime into the carbonate must increase its cohesion, but the rapid setting, to use a workman's phrase, cannot be accounted for in this manner. It appears, so far as we are able to judge in the actual state of applied chemistry, that mortars harden in consequence of the formation of an insoluble silicate of lime and alumina, the silica being either furnished by the limestone itself, or by the sand, pozzolano, or other ingredient mixed with the slaked lime. When the setting has been once effected, the absorption of carbonic acid gas from the atmosphere may tend to harden a thin external film; but the very perceptible character of this film militates against the supposition that the cause producing it can act upon the interior of the mass.

Nevertheless, the numerous classes of limes, cements, and plasters exhibit very marked differences in their manner of resisting the action of the atmosphere. The purer carbonates of lime, when used for the preparation of mortar, are excessively soluble in water; and if the mortar obtained from them be much exposed to the weather or to the action of running water, it will be rapidly removed. The argillaceous limestones, on the contrary, furnish the elements necessary to form an insoluble double salt of lime with the silica and alumina; and if the mortars made from them be protected from running water during the period required for their setting, the action of either weather or running water subsequently, will rather tend to increase their powers of resistance. The practical lesson to be drawn from these facts would appear to be, that none but the limes obtained from argillaceous limestones should be employed in damp situations. With respect to the use of plaster, the observations before made upon the gypseous stones will apply here perhaps with even greater force. Indeed, the marked difference between the external aspects of the applied plaster and the natural stone, would show that in the process of calcination some element we are unable to ascertain must be driven off. It may be that the burnt plaster yields more readily on account of the absence of this very element; but certain it is that plaster of Paris very rapidly decays when exposed to the influence of the atmosphere.

Temperature appears to act in a distinct manner upon limes and cements; for if they are used in summer, without the adoption of any precautions to defend them from the sun, they invariably crack; and of course, if their water of crystallisation becomes frozen in winter, the whole mass will disintegrate. The more rapidly limes or cements solidify, the more they appear to be exposed to the danger and inconvenience of cracking in warm weather, and it would appear that the most favourable condition for their resistance is when a certain degree of uniform moderate dampness prevails. It must also be observed, that sea air has a marked influence upon the durability of some limes, because the minute particles of sea-water it contains hold in solution many salts with which free lime has more affinity than with silica.

The decay of wood superinduced by atmospheric action, is affected by a different class of phenomena from those which tend to destroy stones and metals, namely, those connected with organic chemistry; although at the same time the changes produced by inorganic elements are as powerful in the one case as in the other. From the day when wood is felled to the day it is used, it requires care and attention, and when it is in place, precautions should still be taken to insure its durability. Currents of air which are either renewed with too great rapidity or are too dry, a temperature too elevated, constant moisture at high temperatures, alternations of dryness and humidity, absence of ventilation producing wet rot, the accidental transport by the atmosphere of the seeds of certain cryptogamous plants producing a species of dry rot, and the attacks of insects, together with the fermentation of the sap of the trees, may be cited amongst the numerous sources of danger from which it is necessary to secure wood, either when in store or when employed.

When wood is exposed to frequent currents of air, especially at high temperatures, the moisture it contains evaporates too rapidly, and gives rise to cracks and fissures which either destroy the resistance of the material, or open a passage for the water contained at other times in the atmosphere, to penetrate to the interior of the mass. If the temperature to which wood is exposed, whilst any sap remains in it, is too elevated, the vegetable fluids ferment, the tenacity is diminished, and when the action is carried to its full extent, the wood quickly becomes affected by the dry rot. Exposure to the atmosphere in positions where rain can lodge in quantity, contact with the ground, and application in damp situations deprived of air, will render wood liable to the wet rot; and however well seasoned it may have been previously to being brought within the influence of any of these causes, it will infallibly suffer. It is therefore of the highest importance, that whether in the merchants' stores, or subsequently when placed in a building, wood should be preserved from contact with the ground, and that air should have free access to it in every direction. The germs of destruction are often communicated whilst the wood is in store, from neglect of these simple precautions; if they be once implanted, the progress of decay can never be subsequently arrested. It has been supposed that keeping wood in water tends to prevent the commencement of dry rot, because in that position the sap is washed out of the pores. If this theory is correct, it must be evident that the oftener the water is changed, the greater will be the probability of its producing the desired effect; because if it be allowed to stagnate it must become saturated with the sap in course of time, and unable to take up any additional quantity which may be present. Duhamel observed, that if wood were immersed immediately after it was felled, it would be less liable to decay than if put in water at a subsequent period; he also found that immersion tended to preserve the wood from the attacks of insects, and even to arrest the progress of some kinds of decay, but that a notable portion of the strength was thus lost. The drying and seasoning take place with greater rapidity after immersion, probably because the water displaces the sap, which does not evaporate so rapidly as the thinner fluid. Duhamel asserts that the process of charring the ends of posts, &c., built into the ground, is very inefficient, and that it is only of use to the extent of interposing an extraneous substance between the wood and the earth; in his opinion it would be better to inclose the lower ends in sand, stone, cinders, or other materials which would easily carry off the water supplied by the surrounding media.

When wood is converted and placed in a building, its durability may be greatly increased by covering it with a coating of paint or other substance which will prevent the moisture of the atmosphere from obtaining access to it. But it is essential that the wood so covered should be free from sap or internal moisture, or the very perfection of the coating will be found to accelerate its decay. Care must be taken to prevent water from finding its way into the joints, and if the wood be exposed directly to the action of the sun, it should be painted of a colour able to reflect, rather than to absorb, heat. It is desirable that it should be planed before being painted, in order that the paint may be applied in an equal manner over the surface. It is important also to observe, that the moisture in the atmosphere not only affects the volume of the wood, but frequently alters the position of the fibres, by producing a torsion analogous to that which may be observed in hygrometric cords.

Of late years the processes of Kyanising, creosoting, and immersing timber in solutions of mineral salts, have been applied with various success for preserving it from rot and the attacks of worms or ants. Of these, Kyanising, which employs a solution of deutochloride of mercury, appears to be most satisfactory; and among some striking illustrations of its results may be cited the fence of the Regent's Park, the posts of which were inserted in the ground, without being painted, at least twenty-three years since, and remain at the present day in very tolerable condition. For railways and harbour works, English engineers appear to prefer the system of creosoting, or immersing the timbers in the rough oil of tar, until it has absorbed at least 7 or

8 lb. per cubic foot. The difficulty of injecting so large a quantity of oil is overcome by exhausting the sap and moisture from the wood *in vacuo*, and then forcing in the oil under great pressure; a species of artificial drying is, however, frequently necessary, and indeed the success of this process appears to depend entirely upon the extent to which the original moisture is withdrawn. Both corrosive sublimate and oil of tar are capable of resisting the causes of decay communicated by the atmosphere, and the latter is said to be an effectual preservative against the attacks of boring animals; but it is to be feared that the ordinary manner of applying them does not insure their penetration to a sufficient depth to attain the objects desired. The use of the sulphate of copper and of the other metallic salts has hitherto been unsuccessful.

In the bent timber bridges which have been constructed on some of the modern lines of railway, although every ordinary precaution was taken in selecting the timber, immersing it in solutions of the metallic salts, and in painting it when in place, the wet rot has exhibited itself in so many instances as to render it almost necessary to abandon a system which appeared to have many recommendations. It is, however, to be observed, that these bridges decayed solely because their elasticity caused them to yield upon the passage of every train. The play thus produced caused the joints to open, and moisture, furnished by rain or the condensation of vapour, found its way into the interior of the beams. The failure of the bent timber ribs in such situations does not, therefore, in any manner affect the propriety of using that construction on more suitable occasions. A valuable lesson is, however, to be learnt from the above fact, namely, that it is difficult, if not impossible, to protect complicated systems of carpentry from the effects of the atmosphere, when exposed to the occasional action of heavy loads able to produce a disturbance of their main parts.

The action of the atmosphere upon metals is even more complicated than that which takes place upon stones, because the electro-chemical changes are more decided, and the metallic bases are susceptible of combining with a greater number of gases than are the earthy bases or the metalloids. In building operations the metals commonly used are iron, lead, copper, tin, zinc, with the mixed metals, brass or bronze, and to them we will confine our attention.

Iron, whether cast or wrought, becomes rusted on exposure to the air or water under certain conditions; that is to say, the outer portions of the metal are converted into a hydrous oxide, and can be detached in scales or flakes. Many systems have been proposed to obviate the danger, and many substances applied to correct the evil, arising from this cause, full information concerning which is contained in Mr. Robert Mallet's papers in the Transactions of the British Association for the Advancement of Science. His experiments appear to show that gas tar applied hot is the most efficacious protection for iron work exposed to cold water, and that a coating of caoutchouc varnish resists the longest in hot water; but that neither of them can be considered a durable defence. Cases cited by M. Vicat are within the knowledge of every architect who has examined this class of phenomena, which prove that in some waters, as in some positions in the open air, iron work, totally unprotected, will last an indefinite period. These exceptions are, nevertheless, so rare and the destruction of iron unprotected is generally so rapid both in air and in water, that constant care and attention are required to guard against the destructive tendencies of those agents. If iron work be exposed to the air in positions which render the renewal of the air difficult, and at the same time retain it in a marked degree of dryness, the iron will become covered with a coat of rust, through which the atmosphere cannot penetrate to attack the metal beneath. If the water in which iron is immersed contains a very small portion of some of the earthy salts, the decomposition will take place slowly. But it is necessary to observe that these remarks only apply to iron of considerable dimensions: small wires decay rapidly on exposure to either of these causes of disintegration.

Should iron, however, be exposed to confined air in damp positions, the decay attains its maximum. Carbonic acid gas contributes much to this destruction; for under its influence iron passes (to use the words of Vicat) into the state of the carbonate of protoxide, which, absorbing fresh doses of oxygen, transforms itself into a hydrated peroxide. It is indeed generally considered that oxidation cannot take place to a dangerous extent unless carbonic acid be present; and it is precisely for this reason that iron bedded in fresh masonry or concrete resists the action of the air, because either the mortar absorbs the carbonic gas, which has a greater affinity for lime than it has for iron, or the masonry is sufficiently dense to protect the iron from contact with the atmosphere. The investigations of the Commission in 1850, respecting the fall of the bridge over the Maine, at Angers (recorded in 'Les Annales des Ponts et Chaussées,' vol. xxix. seconde série, page 394), appear to prove that the preservative action of the lime depends upon its being in immediate contact with the iron, and that if a space, however small, be left between the two substances moisture will insinuate itself, and in course of time produce active oxidation. M. Vicat, in a note inserted in the 'Annales des Ponts et Chaussées' for May and June 1853, appears to doubt the correctness of this conclusion, but even he admits that the preservative action of the lime depends upon its absorption of carbonic acid gas, and that directly its hardening ceases, it loses its power of resisting the action of the atmosphere on the iron.

M. Payen found that the addition of very small quantities of the sub-carbonate of potassa, or of sodium, to pure water, was sufficient to render it innocuous either to cast or wrought iron, and the same property existed in nearly all alkaline solutions; whilst, on the contrary, the addition of a small quantity of the chloride of sodium rendered the process of oxidation much more rapid than it usually is in pure water. It appears that gray cast-iron is more susceptible of destruction by oxidation than either wrought iron or white cast-iron; and that wrought iron resists the action of sea water more effectually than cast. It is a peculiar fact connected with this subject, that iron, exposed to frequent displacements, shocks, or vibrations, is less affected by oxidation than when it remains constantly in one place, without disturbance. Thus, anchors in constant use are less exposed to rust than those preserved in the magazine; the rails of the main lines of railroads are less corroded than those in the sidings; iron steamers rust less when in active service than when in dock. But the positions in which iron decomposes with the greatest rapidity are those where it is fixed, and alternately exposed to the air and immersed in sea-water. Ammoniacal and sulphuric acid gas exercise very serious effects upon the durability of cast and wrought iron. It is important, therefore, to prevent their use, either in urinals, roofs over gasworks, or the engine sheds of railway stations. There appears also to be some danger in using iron in contact with sulphate of lime, or in fact under any circumstances where it is likely to take up sulphuric acid gas, for which it has great affinity.

The galvanisation of iron, which, as generally practised, consists in forming a superficial coating upon the metal by immersing it in melted zinc, appears to constitute an efficient protection, so long as the iron is covered. The contact with the zinc brings the iron into an electro-negative state, and it is known that so long as the latter prevails there is little tendency on the part of the iron to combine with oxygen. From a series of experiments made at Brest between the years 1842 and 1851 (see note by M. Dehargne, 'Annales des Ponts et Chaussées,' 1851), it appears that the zincing process does not, in any sensible degree, affect the tenacity or the ductility of the iron; but it is important to secure the protected metal from any shocks or friction likely to remove the surface.

Zinc, when exposed to the atmosphere in its ordinary state, becomes rapidly covered by a whitish efflorescence, which adheres to the metal, and forms, as it were, a species of varnish, capable of arresting any further decay. This efflorescence is considered to be a carbonate of zinc; but if the atmosphere should contain any sulphuric or hydrochloric acid (as in London and in the immediate neighbourhood of the sea), compounds are formed of a nature to compromise the solidity of the metal. In the purer atmosphere of Paris, and other Continental towns, where wood is the ordinary fuel, and to which the sea air does not reach, zinc is employed successfully for roofing purposes; in London, and on the sea shore, its durability is very limited; and at all times its fusibility, and even its combustibility must be a serious objection to its use externally, especially for roofs.

Copper resists the action of the atmosphere very successfully, and the presence of some of the gases mentioned above does not seem to affect it in any material degree. A film of oxide, or carbonate, of copper is rapidly formed over the surface, and secures the metal from further decay. It is found, however, that a mixed metal or bronze, made of copper and zinc, resists the influence of the atmosphere and sea water more successfully than pure copper alone.

Lead undergoes little change upon exposure either to air or water, especially when the latter contains small proportions of the salts of lime. According to Brande, when lead is kept in distilled water to which air has access, small crystalline scales of oxide of lead are formed, a portion of which dissolves in the water, and is again slowly precipitated in the form of a carbonate. Soft water also, or that without the salts of lime, appears to be more likely to attack lead than that containing lime. The use of lead for cisterns must, therefore, be regulated by the nature of the water to be preserved in them; for all roofing or analogous purposes there do not appear to exist any philosophical reasons to object to the use of this metal, or to limit its application to any particular districts.

A very important remark with respect to the use of metals must be made, namely, that when two of them are used in contact, in positions where moisture in any form has access to them, a species of galvanic action is established, which causes them to decay with great rapidity. Illustrations of this may be observed in iron railings, when the bars are secured to the stone curb with lead, and the decay is most evident when the iron is of the best and most malleable description. A similar phenomenon may also be observed when copper or bronze is in contact with iron in sea water; though the iron decays rapidly, it appears to exercise a protective influence upon the copper.

The laws of electricity developed by the contact of two metals with a liquid containing a solution of an alkaline salt, are treated at some length in vol. 1, Gmelin's 'Handbook of Chemistry,' p. 364. From this authority it appears that zinc, tin, and iron, protect copper in sea water. Zinc protects iron and tin plate, but it is not so effective for the defence of iron in sea water if air be present, and it is itself rapidly corroded when used with iron in the sea. In that element tinned iron decays unequally, the iron oxidating whilst the tin remains intact; and appears that the decay, superinduced by the contact with tin, is greater than that resulting from the contact with copper. The corrosion of copper may be considerably retarded by fastening to it at several points, pieces of cast or wrought iron, or of zinc, when sulphuretted hydrogen is likely to be present. Water containing bicarbonate of lime will deposit the lime if placed in contact with zinc and copper, the deposit taking place upon the copper: and when water of this description flows through leaden pipes, the carbonate of lime is deposited at the solder joints (composed of an alloy of tin and lead), on the brass cocks, and on any piece of iron or silver which may be introduced. The inconvenience arising from the stoppage thus produced may be obviated by the use of a lateral pipe fitted to the main at intervals, and furnished with plugs of a metal likely to deposit the calcareous matter, which can thus be withdrawn from the main.

Glass under certain circumstances is affected by the action of the atmosphere; for the potash and soda employed in its manufacture are susceptible of being decomposed and removed by the moisture, or the gases contained in it; and according to Gmelin the decomposition takes place with greater ease in proportion as the glass is richer in the above-named alkalies, and the temperature of the moisture or water is higher. Glass in which there is a deficiency of silica is exposed to this description of decay, which may often be distinctly perceived in window glass, the alkali from which is gradually attracted (Knapp's 'Applied Chemistry,' vol. ii. p. 8) by atmospheric moisture and washed away, whilst a thin layer of silica or of silicate of lime remains upon the surface and exhibits a play of prismatic colours. An analogous decomposition takes place in the glass used in stables, in consequence of the ammoniacal gases; and, according to Knapp, glass containing oxide of lead is liable to blacken on exposure to air impregnated with sulphuretted hydrogen.

The chemical changes produced in oleaginous and metallic pigments by the gases contained in the atmosphere are subjects of the highest importance to the decorative artist; but as the examination of them would extend this notice beyond the usual limits, the reader is referred to the researches of M. Chevreul in the 'Mémoires de l'Académie des Sciences,' 1850 (vol. xxii.). It may here, however, suffice to say that M. Chevreul attributes the solidification of paints to the oils they contain absorbing oxygen from the atmosphere, and states that the driers act by facilitating the power of absorption. The various substances introduced to communicate colour appear to affect the rate of absorption; and the surfaces upon which the paints are applied, have an influence independent of their mere capacity of taking up moisture. The varieties in the rates of drying upon the several woods and metals experimented upon by M. Chevreul, indicate some peculiar differences in this respect, which have not hitherto been sufficiently examined.

[The greater part of this article was read by our contributor, Mr. Geo. R. Burnell, at the ordinary general meeting of the Royal Institute of British Architects, June 5, 1854; and as the notice embraces a great variety of substances used in construction, Mr. Burnell reprints it for general information in preference to any abridgment.]

ATMOSPHERIC RAILWAY. The history of failures constitutes an important part of the history of science and practical art; and, on this ground, the atmospheric railway may suitably receive a little notice here. The idea of producing motion by atmospheric pressure was conceived by Papin, the well-known French engineer, nearly two centuries since. After slumbering for more than a century, the subject was successively taken up by Lewis, Medhurst, Vallance, and Pinkus, and lastly by Clegg, in connection with Jacob Samuda. Medhurst not only cherished the idea of locomotion by atmospheric pressure, but devised many plans for its accomplishment. One of these plans related to the construction of an air-tight tunnel of sufficient magnitude to admit the passage of carriages within it, running upon iron rails, and propelled by air forced in behind them by pumping machinery; the carriages being made so nearly to fit the tunnel that the air thus forced in could not pass them, but must act upon them as upon a piston. Another invented the use of a vacuum in front of the piston, instead of compressed air behind it. A third related to the arrangement of carriages *outside* the tube, connected by mechanism with the air-driven piston inside. In a fourth plan there was to be a smaller tube between the two rails of an iron tramway. Vallance's plan, made public in 1825, related to the conveyance of passengers along a railway laid within an air-tight tunnel, which he proposed to construct either of cast-iron or of vitrified clay, resembling common brickwork, but less permeable to air; but, knowing that experiments had proved a very great loss of power to result from the attempt to impel air through a long pipe, he proposed to set the piston-carriage in motion solely by exhausting the tunnel in advance of it, and suffering the full pressure of the atmosphere to act upon its rear. This plan, which was patented in 1823, was brought into experimental operation at Brighton upon a sufficiently large scale to prove the possibility of so singular a mode of transport; but, had there been no other difficulties, the objections of the travelling public to transmission in a dark close tunnel would have proved sufficient to prevent its general adoption. About the year 1835 the subject was revived in consequence of a patent being taken out by Mr. Henry Pinkus, an American gentleman residing in England, for an apparatus which he called the Pneumatic Railway. This, as originally proposed, was to consist of a cast-iron tube from 36 to 40 inches internal diameter, of an average thickness of three-quarters of an inch, and having a

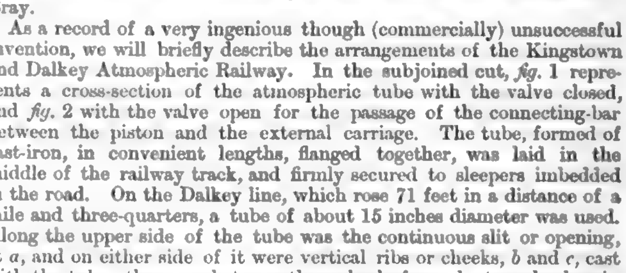
longitudinal slit or opening from one to two inches wide along what was, when laid in its proper position upon the railway, intended to be its upper side; this slit furnished an opening through which the mechanism of the piston inside the tube could be connected with that of the carriages on the outside. Some time afterwards, Mr. Pinkus made trial, on a piece of experimental railway laid down near the Kensington Canal, of a tube much smaller in diameter, and differently arranged; but the experiment led to no immediate results.

In 1840, Messrs. Clegg and Samuda arranged with the West London Railway Company for the temporary use of a portion of their line near Wormwood Scrubs, upon which they laid down about half a mile of railway, with a rising gradient of about 1 in 120; and notwithstanding the defective arrangements, the results of the first trials showed a maximum speed of 30 miles per hour with a load of 5 tons 9 cwt. in one carriage, and of 22½ miles per hour with a load of 11 tons 10 cwt. in two carriages. This experiment was deemed so satisfactory, that the directors of the Dublin and Kingstown Railway determined to adopt the atmospheric mode of working upon a projected extension of their line from Kingstown to Dalkey, the gradients and curves of which rendered it unsuitable for working by locomotive engines. This line was so far completed as to be ready for working in August, 1843. In 1844, the London and Croydon Railway Company obtained parliamentary sanction to a plan for laying down a line of atmospheric railway alongside of their locomotive line from London to Croydon, and making an extension of the same from Croydon to Epsom. About the same time, and within a year or two afterwards, many other atmospheric railway schemes were brought before the notice of Parliament, some of which were sanctioned by Acts.

The result of these schemes has not borne out the expectations of the projectors. The atmospheric system was tried on portions of the Croydon and the South Devon Railways; and after lengthened trials, the costliness and the inconvenience of the system led to the removal of the atmospheric apparatus from those railways. The only line which was worked during a lengthened period was that of the Kingstown and Dalkey Railway; but even that was ultimately abandoned in favour of locomotive engines, when the line was extended to Bray.

As a record of a very ingenious though (commercially) unsuccessful invention, we will briefly describe the arrangements of the Kingstown and Dalkey Atmospheric Railway. In the subjoined cut, *fig.* 1 represents a cross-section of the atmospheric tube with the valve closed, and *fig.* 2 with the valve open for the passage of the connecting-bar between the piston and the external carriage. The tube, formed of cast-iron, in convenient lengths, flanged together, was laid in the middle of the railway track, and firmly secured to sleepers imbedded in the road. On the Dalkey line, which rose 71 feet in a distance of a mile and three-quarters, a tube of about 15 inches diameter was used. Along the upper side of the tube was the continuous slit or opening, at *a*, and on either side of it were vertical ribs or cheeks, *b* and *c*, cast with the tube; the space between these cheeks formed a trough wherein the valve lay secure from injury. The valve itself consisted of a piece of strong leather, firmly enclosed between two pieces of iron. The leather was on the side marked *b*, considerably wider than the upper plate, and its projecting edge was attached to the flat floor of the valve-trough, at the base of the cheek *b*, so as to form a continuous hinge. The more perfectly to prevent the ingress of air, the opposite or opening edge of the valve was, when closed as in *fig.* 1, hermetically sealed with a composition of wax and tallow, which filled the small groove or space left between it and the cheek *c*. To protect the valve more thoroughly, the trough was closed in with a sheet-iron cover *d*, hinged with leather to the top of the cheek *b*, and shutting down closely upon the top of the cheek *c*. The interior of the tube was lined with a soft composition, which filled up all little irregularities, and rendered the passage perfectly smooth and even. The piston was attached to the fore end of a rod which is seen in

Fig. 1. *Fig.* 2.



section at *f*, and which carried rollers so fixed as to lift up and open the valve immediately after the piston had passed, thus bringing it into the position indicated in *fig.* 2. This position allowed room for the passage of the connecting-bar *e*; the iron cover *d* being previously raised and held open by a coulter and a series of wheels or friction-rollers attached to the carriage. After the connecting-bar had passed, a roller attached to the carriage pressed the valve down into its seat, while a heater gliding along the mass of composition at its opening edge melted it, thereby sealing the joint afresh. The cover *d* was then allowed to fall into its place, and all was ready for the passage of another train as soon as the piston had quitted the pipe so as to allow of its being exhausted afresh. The end of the tube behind the train was left open, to admit the air by which the piston was to be impelled; but the end in advance of the train was closed, and the air was pumped out from the tube by a branch pipe near it, leading to the air-pumps. These pumps could be worked either by a steam-engine or by any other prime mover of sufficient power. The mode of action, then, was as follows: the train of carriages was pushed forward by manual labour until the piston had entered the tube; which it might do, by the aid of an ingeniously contrived valve, without impairing the partial vacuum previously produced. It then advanced with a speed proportionate to the rate at which air was abstracted from the tube by the air-pumps until it reached the opposite end of the tube, where, without the aid of an attendant, the valve which had closed the tube sprang open, and the piston and train proceeded by momentum until stopped by breaks. At Dalkey the inclination of the road was sufficient to produce rapid motion in one direction by gravity alone; so that the atmospheric pressure was only required in ascending, while in descending the piston was moved aside in such a way as to pass clear of the tube. In longer and in level lines of railway there would necessarily be a greater complexity of arrangement. It was this complexity that led to the subsequent abandonment of all the schemes.

The main arguments in favour of the atmospheric system of traction are based upon the facilities which it affords for ascending steep gradients, and consequently for constructing railways at less cost than where heavy cuttings and embankments are necessary in order to procure easy slopes for the locomotive; the saving in the wear and tear, and consequently in the necessary strength and cost of the railway itself, in consequence of not having to convey the moving power with the train; and the security against collision, owing to the impossibility of moving two trains on the same stage or engine-length of railway at the same time. The objections raised to this apply to every other mode of using stationary engines; such are the necessity of providing and constantly maintaining a power sufficient to conduct the largest amount of traffic which can ever be conveyed, which would render it as costly, as regards some large items of expense, to maintain a railway for the passage of four or five trains per diem as one upon which trains are constantly succeeding each other; and the liability of derangement to the whole system in consequence of the failure of a single point in it. These are the principal grounds for objection to what has been termed the *inflexibility* of the system, or, in other words, the comparative want of power to modify the mode of working according to the fluctuations of a variable traffic or the exigencies arising from accident. It is this inflexibility, together with the waste of power which results from any defect in the valve, that led to the abandonment of the system. It would be too much, however, to say, that the system, though at present in abeyance, is unsuited for further application. [RAILWAY.]

ATOMIC THEORY, in chemistry, sometimes termed the *doctrine of definite proportions*. This very important theory, founded on well-ascertained facts, has bestowed on modern chemistry an almost mathematical degree of precision. The hypothetical, which is to be distinguished from the experimental part of the subject, supposes that chemical compounds result from the combination of the ultimate atoms of their constituent parts. It has been determined by experiment, and the fact serves as the basis of the theory, that a compound body, when pure, always contains the same proportions of its constituents: thus, calcareous spar, and the pure part of marble, chalk, and limestones, consist of carbonate of lime, composed of the same proportions of carbonic acid and lime; the carbonic acid always contains the same quantity of carbon and oxygen, and the lime the same proportions of calcium and oxygen. The same law also exists with regard to all similarly-constituted oxides, sulphurets, and salts, and indeed as to all chemical compounds whatever, whether presented to us by nature or formed by art: this is a simple statement of the fundamental facts upon which the superstructure of the atomic theory has been raised.

Before we proceed to detail the minutiæ of the theory, it will be proper to give a sketch, though a slight one, of the principal discoveries connected with the subject.

The earliest experiments which could have served as a basis for the atomic theory are those of Wenzel, a German chemist, who published, in 1777, a work 'On the Affinities of Bodies;' the experiments detailed in it, though neglected at the time, are now acknowledged to possess a very considerable degree of accuracy. The author showed that when any two neutral salts decomposed each other, the resulting new compounds were exactly neutral. "The very attempt," remarks Dr. Thomson, "to analyse the salts was an acknowledgment that bodies united with each other in definite proportions; and these definite proportions, had they been followed out, would have ultimately led to the doctrine of atoms." ('History of Chemistry,' vol. ii. p. 278.)

With reference to this subject, it is observed by Sir H. Davy, that "there may be found in the works of Dr. Bryan Higgins, Mr. William Higgins, and Professor Richter, hints or conclusions bearing directly on this doctrine. Dr. Bryan Higgins, in his 'Experiments and Observations relating to Acetic Acid, Fixable Air, Dense Inflammable Air, &c.,' published in 1786, contends, that elastic fluids unite with each other in limited proportions only; and this depends upon the combination of their particles or atoms with the matter of fire which surrounds them as an atmosphere, and makes them repulsive of each other; and he distinguishes between simple elastic fluids, as composed of particles of the same kind, and compound elastic fluids, as consisting of two or more particles combined, in what he calls molecules, definite in quantity themselves, and surrounded by definite proportions of heat. Dr. Bryan Higgins's notions have, I believe, never been referred to by any of the writers on the atomic theory. Mr. William Higgins's claims have, on the contrary, often been brought forward. Yet, when it is recollected that this gentleman was a pupil and relation of Dr. Bryan Higgins, and that his work, called the 'Comparative View,' was published some years after the treatises I have just quoted, and that his notions are almost identical (with the addition of this circumstance, that he mentions certain elastic fluids, such as the compounds of azote, consisting of one, two, three, four, and five particles of oxygen to one of azote,) it is difficult not to allow the merits of prior conception, as well as of very ingenious illustration, to the elder writer." ('Discourse before the Royal Society,' 1826.)

In justice however to Mr. Higgins, it must be admitted that his views were much more extended than those of Dr. Higgins; for it appears that he entertained precisely the same notion of the composition and atomic constitution of water as that now generally admitted, in this country at least. In his 'Comparative View of the Phlogistic and Antiphlogistic Theories,' published in 1790, p. 37, he says, "As two cubic inches of light inflammable air require but one of dephlogisticated air to condense them, we must suppose that they contain an equal number of divisions, and that the difference of their specific gravity depends chiefly on the size of their ultimate particles; or we must suppose that the ultimate particles of light inflammable air require two or three, or more, of dephlogisticated air to saturate them. If this latter were the case, we might produce water in an intermediate state, as well as the vitriolic or the nitrous acid, which appears to be impossible; for in whatever proportion we mix our airs, or under whatsoever circumstances we combine them, the result is invariably the same. This likewise may be observed with respect to the decomposition of water. Hence we may justly conclude, that water is composed of molecules formed by the union of a single particle of dephlogisticated air to an ultimate particle of light inflammable air, and that they are incapable of uniting to a third particle of either of their constituent principles."

It is a remarkable circumstance, that although Mr. Higgins's view of the atomic constitution of the five compounds of oxygen and azote is that which is even now very commonly admitted, he does not state their composition; and his idea of the comparative atomic constitution of sulphurous and sulphuric acids is decidedly erroneous. "Indeed," as remarked by Sir H. Davy in the discourses above quoted, "neither of the Higginses attempted to express the quantities in which bodies combine by numbers."

In 1792, Richter, a Prussian chemist, published a work called 'Elements of Stochiometrie; or the Mathematics of the Chemical Elements.' This author treated the subject almost in the same way as Wenzel had previously done, but extended it very considerably; he endeavoured to determine the capacity of saturation of each acid and base, and to indicate by numbers the weights which mutually saturate each other. He published a table of these, but though the attempt was new and exceedingly ingenious, the results were far from accurate.

The discoveries of Proust, a French chemist who was professor of chemistry at Madrid, are well worthy of notice, he being the first person who attempted an accurate analysis of metallic oxides. He found that metals unite only with determinate proportions of oxygen, and that the same law existed with sulphur and the metals, and that these might be stated in numbers: his opinions were strenuously opposed by Berthollet, but their accuracy is now generally admitted.

In the year 1803, Mr. (afterwards Dr.) Dalton, of Manchester, communicated to the Literary and Philosophical Society of Manchester an essay containing an outline of his speculations on the subject of the composition of bodies ('Manchester Memoirs,' second series, vol. i. p. 286). The following year he explained his notions on the subject to Dr. Thomson, and in 1808 he published the first volume of his 'New System of Chemical Philosophy,' in which he gave an outline of his views of the constitution of matter, and this without any acquaintance with what had been previously done on the subject by Higgins.

Dr. Dalton was unquestionably the first who laid down, clearly and numerically, the doctrine of multiples, and endeavoured to express by simple numbers the weights of bodies believed to be elementary. He announced it as a general rule, that "when only one combination of two bodies can be obtained, it must be presumed to be a *binary* one, unless some cause appear to the contrary." Consistently with this law, and correctly at the time it was written, Dr. Dalton regarded water as a binary compound of hydrogen and oxygen, and the relative weights, since corrected, are considered as one to eight. As, then, water consists of an atom of hydrogen and an atom of oxygen, either of these elements may be selected as unity, and, in fact, as we shall hereafter notice, both have been occasionally employed as such. Dalton fixed on hydrogen, because it is that body which unites with others in the smallest proportion: thus, then, we have water composed of one of hydrogen by weight, or one atom, and eight of oxygen by weight, or one atom, and in all cases an atom of hydrogen being represented by 1, an atom of oxygen will be represented by 8; and these being the atomic weight of the elements, that of the compound will be obtained by adding them together, thus—

Hydrogen	1 atom = 1
Oxygen	1 atom = 8
Water	1 atom = 9

The weight, then, of a compound atom is obtained by adding together the atomic weights of its constituents. Although many elementary bodies unite with hydrogen, there are some which do not, but there is no one which does not combine either with hydrogen or with oxygen; when, therefore, the hydrogen standard or unit fails on this account, we may refer to the atom of oxygen, and determine what weight of the substance in question, supposing only one compound to be formed, unites with eight parts by weight, or one atom of oxygen. Now cadmium is a metal of this description; it forms no compound with hydrogen, and only one with oxygen, and as 8 parts of this element unite with 55·74 of the metal, to form the only known oxide of it, we say that the atomic weight of cadmium is 55·74, and that the oxide is composed of

Oxygen	1 atom = 8
Cadmium	1 atom = 55·74
Oxide of cadmium	1 atom = 63·74

It is, however, possible, though by no means probable, that such an inference may be incorrect, for the oxide in question may be composed either of two or more atoms of oxygen united with one atom of the metal, or the contrary, instead of what it is presumed to be; but the error may be detected by examining the proportion in which the metal unites with other elements, whose atomic weights are already determined. The atomic weights of sulphur, chlorine, and selenium, are respectively 16, 36, and 40: now if, in a series of combinations with these substances, the compounds containing the largest proportion of metal were constituted of

Sulphur	16	Chlorine	35·49	Selenium	39·62
Metal	55·74	Metal	55·74	Metal	55·74

we should then conclude, as these agree with the composition of the oxide, as above given, that 55·74 is the atomic weight of the metal. But if it was found that the compounds in question containing the largest proportion of metal were constituted of

Sulphur	16	Chlorine	35·49	Selenium	39·62
Metal	111·48	Metal	111·48	Metal	111·48

we should conclude that the atomic weight of the metal was 111·48, and consequently that the oxide formed of 8 oxygen and 55·74 metal, was a peroxide, equivalent to 16 = 2 atoms of oxygen + 111·48 = 1 atom of metal.

If, on the other hand, it appeared that the compound containing the argest proportion of metal consisted of

Sulphur	16	Chlorine	35·49	Selenium	39·62
Metal	27·87	Metal	27·87	Metal	27·87

we must then consider the oxide composed of 8 oxygen and 55·74 metal as a *suboxide*, constituted of 1 atom of oxygen = 8 + 2 atoms of metal = 57·74.

This method of proceeding is according to the rule thus laid down by Dr. Dalton: "It is necessary not only to consider the combinations of A with B, but also those of A with C D E, &c., as well as those of B with C D, &c., before we can have good reason to be satisfied with our determination as to the number of atoms which enter into the various compounds." ('New System of Chemical Philosophy,' vol. ii. p. 300.)

In fact, the protoxide of a metal, that is, 1 atom oxygen + 1 atom metal, may possess such properties as to prevent its composition from being by direct means accurately ascertained; and it is likewise possible that no protoxide may exist.

We have alluded to the circumstance, that various compounds of the same two elements may exist, and supposing an elementary body, as tin or copper united with two proportions of oxygen, various questions may arise as to the constitution of the resulting oxides; as, whether that which contains least oxygen is a suboxide, or protoxide; or whether that which contains most is a protoxide or a peroxide. These are points which can be determined only by comparison: for example, with respect to oxygen and tin, that oxide which contains least oxygen consists of 8 oxygen + 58·82 metal; that which contains most, of 16 oxygen + 58·82 metal: now, in this case, we consider that which contains *least* oxygen as composed of 1 atom of each of its elements, and that which contains *most* oxygen as formed of 2 atoms of oxygen + 1 atom of tin, thus

Oxygen . .	1 atom = 8	Oxygen . .	2 atoms = 16
Tin . .	1 atom = 58·82	Tin . . .	1 atom = 58·82
Protoxide of tin	1 atom = 66·82	Peroxide of tin	1 atom = 74·82

This rule of assuming that oxide to be a protoxide which contains least oxygen will be generally found correct, especially when confirmed, as it is in this instance, by the corresponding constitution of the two chlorides and two sulphurets. The oxides of copper, however, form an exception, though a comparatively rare one, to this rule; there are two oxides of this metal composed of

Oxygen	8	Oxygen	8
Copper	63·3	Copper	31·65

Now in this case, the oxide containing the largest proportion of copper is regarded as a suboxide, and that containing the smallest proportion as a protoxide, from certain considerations derived from the chemical behaviour of these two oxides. In general however, the rule may be relied upon, that the metallic oxide which contains least oxygen is the protoxide, and that weight of the metal which combines with 8 by weight of oxygen, denotes the weight of its atom, and their united weight that of the oxide.

It will be observed with respect to the compounds of oxygen and tin, that the second portion of that element which unites with the same quantity of the metal, is double the first. Now upon this and numerous similar facts is founded one of the most important and beautiful peculiarities of Dr. Dalton's theory, sometimes described as the *doctrine of multiple proportions*. In the case just alluded to, the second portion of oxygen is precisely double the first; but there are some cases in which the greater proportions are not multiples of the less, by any entire number: for example, there are two well-known oxides of iron consisting of

Oxygen	8	Oxygen	12
Iron	28	Iron	28

The first of these is the protoxide, and the second the peroxide; but it will be observed, the second portion of oxygen is only one half greater than the first, instead of double, as happens with respect to tin. In fact, the additional quantity is equal to only half an atom of oxygen; but as the idea of dividing an atom is absurd, the difficulty is overcome by multiplying both the oxygen and iron by 2, in which case we shall have $12 \times 2 = 24$, or 3 atoms of oxygen, combined with $28 \times 2 = 56$, 2 atoms of iron, and these proportions are perfectly consistent with the theory.

Other cases of apparent anomaly occur: thus there are three oxides of lead, viz.,

Protoxide.		Red oxide.		Peroxide.	
Oxygen	8	Oxygen	10·66	Oxygen	16
Lead	103·57	Lead	103·57	Lead	103·57

The first and last of these oxides are constituted exactly as the oxides of tin are, the second portion of oxygen being double that of the first; but the red oxide of lead is composed of an atom of metal and such a quantity of oxygen as is equal to one atom and a third. If, then, both the oxygen and metal be multiplied by 3, we shall have a compound of 4 atoms of oxygen and 3 atoms of lead, or 32 + 310·71 = 342·71, and it is found if these 342·71 parts of red lead be treated with dilute nitric acid, they are separated into 2 atoms of protoxide = 111·57, which are dissolved, and 1 atom of peroxide = 119·57, which remains unacted upon in the state of a brown powder. This case, then, of apparent anomaly is explained by showing that the red oxide of lead is equivalent to, or perhaps composed of, the other two oxides, and is resolvable into them.

The oxides of manganese offer a still more remarkable case of apparent irregularity of combination, and of the disposition of metallic oxides themselves to combine in definite proportions.

While on the subject of multiples, it will be proper to adduce one of the most remarkable and regular series of them presented to us. There are five compounds of oxygen and nitrogen, viz.,

	Oxygen.	Nitrogen.
Nitrous oxide, composed of	8 = 1 atom	+ 14 = 1 atom.
Nitric oxide . . .	16 = 2 atoms	+ 14 = „
Hyponitrous acid . .	24 = 3 „	+ 14 = „
Nitrous acid . . .	32 = 4 „	+ 14 = „
Nitric acid	40 = 5 „	+ 14 = „

In these compounds, it will be observed, that to form a new compound, 1 atom of oxygen is in every case added to the preceding quantity, and that the atoms of oxygen combined with 1 atom of nitrogen, are 1, 2, 3, 4, and 5.

The case in which the second portion of oxygen in an oxide, instead of being equal to the first, is only one half greater, has been pointed out in the instance of the oxides of iron, and the means by which the absurdity of supposing the existence of half an atom is obviated have been mentioned. Such oxides are, however, generally termed *sesquioxides*, and there are also several instances in which secondary compounds are similarly constituted; these are in like manner termed *sesquisalts*. The alkalies ammonia and soda, and some other bases, form three compounds with the same acid: for example, we have

Carbonate of soda, composed of	1 atom acid + 1 atom base
Bicarbonate of soda,	2 atoms acid + 1 atom „
and a carbonate of soda,	3 atoms acid + 2 atoms „

It is then evident that the last salt is equivalent to a compound of $1\frac{1}{2}$ atom acid + 1 atom base. Now if an atom of this salt, considered as a sesquisalt, be added to an atom of nitrate of lime, double decomposition ensues, 1 atom of neutral nitrate of potash remains in solution, 1 atom of neutral carbonate of lime is precipitated, and carbonic acid equal to half an atom is expelled in the state of gas. With respect to its *base* then, sesquicarbonate of potash may be regarded as a neutral carbonate, though, as to its acid, as a sesquicarbonate; for if lime-water be added to an atom of a sesquicarbonate, carbonate of lime is precipitated equivalent in quantity to 1½ atom.

It may now be easily made to appear how it happens that when two neutral salts decompose each other, the new salts obtained by the operation are also neutral; an atom of nitric acid weighs 54, and one of baryta 76·64, forming when combined, 130·64 of neutral nitrate of baryta; 86·96 = an atom of neutral sulphate of potash is composed of an atom of sulphuric acid = 40, and an atom of potash = 46·96. Now, when 130·64, or an atom of nitrate of baryta, dissolved in water, is mixed with a solution of 86·96, or an atom, of sulphate of potash, double decomposition ensues, and two new and perfectly neutral salts are formed, namely, 1 atom of nitrate of potash = 100·96, consisting of an atom of nitric acid = 54, and an atom of potash = 46·96; this remains in solution; and there is precipitated an atom of neutral sulphate of baryta = 116·64, composed of 1 atom of sulphuric acid = 40, and 1 atom of baryta = 76·64. The annexed diagram will show the constitution of the salts employed, and those formed by their mutual decomposition; and it will be seen also, that the weight of the new compounds is precisely equal to those of the original salts.

100·96 Nitrate of Potash.

54 Nitric acid. Potash 46·96.

130·64 Nitrate of Baryta.

86·96 Sulphate of Potash.

76·64 Baryta. Sulphuric acid 40.

116·64 Sulphate of Baryta.

Although the atomic theory, thus developed by Dr. Dalton in 1808, contained truths of the highest importance, quite independent of the hypothesis by which they were illustrated, it was not until after the appearance of Dr. Wollaston's Memoirs, 'On Super-acid and Sub-acid Salts,' and 'On a Synoptic Scale of Chemical Equivalents,' that chemists were fully impressed with the practical applications of which the theory was susceptible. In the first memoir ('Phil. Trans.' 1808), a memoir equally remarkable for its conciseness and clearness, Dr. Wollaston shows, that Dr. Dalton's theory, first applied to determining the constitution of gaseous bodies, is applicable to that of acid and basic salts; and he proves that carbonate of potash contains exactly half the quantity of carbonic acid existing in the bi-carbonate, by showing that if the latter be heated it loses half its acid, and is reduced to the state of carbonate by the loss; the same rule was found to exist with the carbonate and bi-carbonate of soda, the sulphate and bi-sulphate of potash, and with three oxalates of potash.

The paper on the *synoptic scale* appeared in the 'Phil. Trans.' for 1814. By this instrument the practical utility of the doctrine of definite proportions was most satisfactorily pointed out.

This instrument consists of a moveable scale of numbers on the principle of Gunter's scale, so that any number can be placed opposite the names of a series of substances in adjoining columns, arranged in the order of their combining weights, in such a manner that the number denoting the combining weight of a body being placed opposite to its name, 8, for example, opposite to oxygen—the numbers expressing the combining quantities of others will appear opposite to their names; thus copper will be found opposite to 31·65, showing that this quantity of it combines with 8 of oxygen, and opposite to 39·65 will be found oxide of copper. By mere inspection, a great number of important results are obtained. If the composition of a substance with regard to the proportion of its elements is to be determined, the slider is to be so placed that the number 100, or any required number, is opposite to its name, and the respective quantities of the ingredients will be found opposite to their names, and the quantities of other compounds required to decompose them: for example, when 68·96 is placed opposite to carbonate of potash, 22 will be opposite to carbonic acid, 46·96 to potash, 49 to oil of vitriol, 40 to dry sulphuric acid, and 9 to water. Now it is well known that carbonate of potash is decomposed by sulphuric acid; and on further inspecting the scale, it will be observed that sulphate of potash, the newly-formed salt, is opposite to 86·96, showing the quantity formed by the union of 40 of dry sulphuric acid and 46·96 of potash, while 22 of carbonic acid are expelled, and 9 of water are set free. This simple example is sufficient to show the very extensive use which by mere inspection, may be made of this instrument, in exhibiting the constitution of various oxides, acids, and salts, and of the quantities of substances required to form or decompose compound bodies.

The use of the term *atom* has been objected to as hypothetical, because it is said that we have no means of ascertaining or judging of the weight or magnitude of an atom of any element, and that any supposed relative weight of their atoms must therefore be a mere hypothetical assumption, from which no satisfactory conclusion can be drawn; and by those who appear to entertain this opinion, other terms, such as *equivalent number, molecule, combining proportion*, &c. have been substituted for the word atom.

In the year 1808, Berzelius, in consequence of a perusal of Ritcher's work already alluded to, undertook an investigation of the numerical proportions in which different bodies combine so as to neutralise each other; these investigations were accompanied by a series of analyses which for number and accuracy have probably never been equalled. As the results of these labours, he laid down certain laws relative to chemical combinations, which, however, are in general only to be considered as corollaries from those determined by Dalton. From these analyses subsequently extended and corrected, a large number of the atomic weights given in the table below have been derived, but in all cases where more recent researches have either indicated errors in the numbers obtained by Berzelius, or have added new elements to the list, the results of these researches have been embodied in the table.

In constructing tables of atomic weights several standards have been proposed by different chemists, but only two of these have been retained in use, namely, the standard proposed by Dalton, Hydrogen = 1; and that adopted by Berzelius, Oxygen = 100. The former is almost universally employed in this country, whilst the latter is almost as generally used on the continent. Both these standards are used in the following table:—

TABLE OF THE ATOMIC WEIGHTS, OR COMBINING PROPORTIONS OF ELEMENTARY SUBSTANCES.

Name of Element.	Atomic Weight. Hydrogen = 1	Oxygen = 100.
Aluminium	13·67	170·90
Antimony	129·03	1612·90
Arsenicum (Metallic arsenic)	75·00	937·50
Barium	68·64	858·03
Bismuth	212·86	2660·75
Boron	10·90	136·20
Bromine	79·97	999·62
Cadmium	55·74	696·76
Calcium	20·12	251·31
Carbon	6·00	75·00
Cerium	46·00	575·00
Chlorine	35·49	443·67
Chromium	26·27	328·38
Cobalt	29·49	368·65
Copper	31·65	395·60
Didymium	48·00	600·00
Erbium		
Fluorine	19.00	237·50
Glucinum	6·97	87·12
Gold	98·33	1229·16
Hydrogen	1·00	12·50
Ilmenium		
Iodine	126·88	1585·99
Iridium	98·56	1232·08
Iron	28·04	350·50
Lantanium		
Lead	103·57	1294·64
Lithium	6·53	81·66
Magnesium	12·65	158·14
Manganese	27·57	344·68
Mercury	100·10	1251·29
Molybdenum	47·69	596·10
Nickel	29·54	369·33
Niobium		
Nitrogen	14·00	175·06
Osmium	99·41	1242·62
Oxygen	8·00	100·00
Palladium	53·24	665·47
Phosphorus	32·02	400·30
Platinum	98·56	1232·08
Potassium	38·96	487·00
Rhodium	52·16	651·96
Ruthenium	52·11	651·39
Selenium	39·62	495·28
Silicon	21·36	267·00
Silver	108·00	1350·00
Sodium	22·97	287·17
Strontium	43·84	548·02
Sulphur	16·00	200·00
Tantalum, or Columbium		
Tellurium	64·08	801·76
Terbium		
Thorinum	59·50	743·86
Tin	58·82	735·29
Titanium	24·12	301·55
Tungsten	94·64	1183·30
Uranium	60·00	750·00
Vanadium	68·46	855·84
Yttrium		
Zinc	32·52	406·59
Zirconium	33·58	419·73

With respect to the utility of the atomic theory, we cannot do better, in concluding this account of it, than to state, in the words of Dr. Daubeny ('Introduction to the Atomic Theory,' p. 87), that "it would be superfluous to enlarge upon the proofs already afforded, with respect to the greater precision it has introduced into the science,—the wonderful saving of time and labour which is derived from it, not only by the philosopher in his more speculative inquiries, but even by the manufacturing chemist, in the every-day operations of his trade."

It is evident that, in the present state of our knowledge, no sooner have we ascertained the exact proportion in which a new substance unites with any one of those bodies whose atomic weight is already determined, than we are enabled to calculate in what quantities it must combine with all the remainder, so that, instead of being compelled, as heretofore would have appeared necessary, to analyse every existing combination, in order to determine the proportion of its ingredients, we might rest contented, were it not for the sake of obviating the chances of error in any single experiment, with ascertaining the composition of one out of the whole number of compounds, into which the ingredient in question enters. [CHEMICAL EQUIVALENTS; MOLECULES; CHEMICAL AFFINITY.]

ATOMIC VOLUME. The equivalent or atomic weight expresses the relation of *weight* in which bodies combine with each other. The atomic volume, or, as it is also called, the equivalent, specific, or molecular volume, expresses the relation of *volume* in which substances combine. If the equivalent weights of two substances are to each other as A : B, and their specific gravities as $a : b$, then the spaces occupied by these equivalent weights are as $\frac{A}{a} : \frac{B}{b}$. In other words, the atomic volume of a body is the quotient obtained when the equivalent of a body is divided by its specific gravity; or atomic volume $= \frac{\text{equivalent weight}}{\text{specific gravity}}$.

The atomic volume is not an absolute quantity; it only expresses a relation. Depending on the equivalent, it will differ according as the equivalent is based on the scale in which oxygen = 100, or on that in which oxygen = 8; it will also differ according to the assumed unit of specific gravity: only the atomic volumes of those substances are comparable whose specific gravities are based on a common unit. Gases and vapours, whose densities are based on that of atmospheric air as unity, may be compared with each other; and solids and liquids, whose densities are based on that of water as unity may be compared; but the atomic volumes of gases cannot be compared with those of solids and liquids.

The following is a list of the atomic volumes of some gases and vapours:

	Atomic Weight.	Spec. Gravity. Air = 1.	Atomic Volume.
Oxygen	8	1·108	7·22
Phosphorus	32	4·294	7·22
Arsenic	75	10·388	7·22
Hydrogen	1	0·069	14·44
Nitrogen	14	0·969	14·44
Chlorine	35·5	2·458	14·44
Mercury	100·1	6 925	14·44
Water	9	0·623	14·44
Carbonic acid	22	1·524	14·44
Hydrochloric acid	36·5	1·264	28·88
Ammonia	17	0·589	28·88
Chloride of ethyle	64·5	2·233	28·88
Acetic acid	60	2·078	28·88
Valerianate of ethyle	130	4·501	28·88

It will be seen that the atomic volumes of the elementary substances in this table stand to each other in a very simple relation. They have an atomic volume either equal to that of oxygen, as in the case of phosphorus and arsenic, or twice as great, as in the case of chlorine, hydrogen, and nitrogen.

When two gases combine, they do so in simple relations of volume, and the volume of the resultant compound, considered in the state of gas, is either equal to the sum of the volumes of the constituent gases, or stands in a simple relation thereto. Thus, two volumes of hydrogen combine with two volumes of chlorine to form four volumes of hydrochloric acid gas; two volumes of hydrogen and one volume of oxygen combine to form two volumes of steam; two volumes of nitrogen and one volume of oxygen combine to form one volume of nitrous oxide; two volumes of nitrogen and six volumes of hydrogen combine and are condensed to four volumes of ammonia.

A substance whose atomic volume in the gaseous or vaporous state is equal to that of oxygen, or is two or four times as great, is said to exhibit a condensation to one, two, or four volumes. It will be seen that the organic compounds enumerated in the above table all exhibit a condensation to four volumes; and it has been almost invariably found that all organic bodies present the same regularity. Hence, in fixing the equivalent of any new compound, a determination of the vapour density is an almost indispensable preliminary, as the following example may serve to illustrate. The vapour density of the substance furfurol was found to be 3·375, and analysis gave for it a composition whose simplest expression is $C_5H_2O_2$; these data would give for furfurol an atomic volume expressing a condensation to two volumes, an unusual fact with organic bodies. But the formula $C_{10}H_4O_4$, which equally well expresses the composition, gives for the atomic volume a condensation to four volumes, and thus brings it in accordance with other organic substances; and on this account, and also because it better expresses the decompositions, the latter formula has been adopted.

We do not notice in the atomic volumes of solids and of liquids those regularities which prevail among the atomic volumes of gases and vapours. Thus, the atomic volume of iron is 5·3; that of platinum, 4·6; of cadmium, 6·5; of tin, 8·0; of lead, 9·2; of arsenic, 13·3; of antimony, 17·9; of sodium, 23·7; of iodine, 25·7; of potassium, 45·6. But it must be remarked, that these specific gravities (and therewith the atomic volumes) have not been determined for uniform conditions. The specific gravity of a body may vary according as it is crystalline or amorphous, or with its crystalline form if it be dimorphous. The various solid elements have very different melting points; some of the specific gravities have been determined at points very near the melting temperature, as phosphorus, sodium, &c.; others at points very distant, as platinum: the atomic volume is only known for the mean temperature of the atmosphere, and hence very unequally distant from the melting points. Probably if the specific gravities were determined for really comparable temperatures, at or near the melting points, for example, the atomic volumes would no doubt exhibit more simple relations.

In certain groups of chemically similar elements the atomic volumes do exhibit agreement: for example, iron 3·6, cobalt 3·5, manganese 3·5, nickel 3·4, iridium 4·5, palladium 4·6, platinum 4·6, molybdenum 5·3, and Tungsten 5·3; lithium 11·8, sodium 23·7, and potassium 45·6, stand very nearly in the relation 1 : 2 : 4. Those elements have generally the same atomic volume which are either isomorphous or can replace each other in isomorphous compounds.

It has been shown by Kopp that bodies with a similar composition and the same crystalline form have also the same atomic volume. Thus, carbonate of strontia (strontianite), $SrOCO_2$, and carbonate of lead (cerusite), $PbOCO_2$, have the atomic volumes 20·5 and 20·7; sulphate of magnesia, $MgOSO_3 + 7HO$, and sulphate of zinc, $ZnOSO_3 + 7HO$, which have the same crystalline form, have the atomic volumes 70·2 and 70·5.

Many carbonates, as of magnesia, $MgOCO_2$, manganese, $MnOCO_2$, lime, $CaOCO_2$, and of iron, $FeOCO_2$, crystallise in the same form, that of the rhombohedron, but differ in the degree of inclination of the corresponding angles; and it has been noticed that the greater the agreement in the corresponding angles, the greater the agreement in the atomic volume.

The relation between the atomic volumes of a solid compound, and of its constituents, has not yet been sufficiently investigated, but the regularity has been observed which was first pointed out by Schröder. That when from the atomic volumes of analogous compounds, the atomic volumes of the corresponding constituents be subtracted, the common remainder is in many cases the same. Thus the atomic volumes of the analogous oxides of copper, and of zinc, are respectively 6·2 and 7·2; if from these the atomic volumes (3·6 and 4·6) of the corresponding metals be subtracted, the atomic volume of the remainder is found to be the same 2·6. The atomic volumes of lead and silver are respectively 9·2. By their conversion into the nitrates they undergo the same increase of equivalent, and the atomic volumes of the nitrate of lead, and of silver, are respectively 38·7 and 39·9; if from these numbers the atomic volumes of the metals be subtracted, the remainders 29·5 and 29·7 will be seen to be sensibly equal. The atomic volume of oxygen in binoxide of tin is 1·3, in the oxides of zinc, lead, and copper it is 2·6, and in suboxide of copper 5·2, numbers which stand in a simple relation to each other; but in many cases in which the atomic volume of oxygen has been determined, such regularities do not obtain.

The atomic volumes of liquids appear to exhibit relations when compared at their boiling points. Isomeric liquids, with unequal boiling points, when compared at the same temperatures have various atomic volumes, but when the expansion of the liquids is known; and their specific gravities, and therewith their atomic volumes, be calculated for the boiling points, the atomic volumes will be found to agree. Thus acetic acid and formiate of methyle, both $C_4H_4O_4$, which boil respectively at 118° and 36°, have at the boiling points the atomic volume 63·5; at 0° the atomic volume of the former is 55·7, and of the latter 60·1.

It has also been noticed that a common difference in the atomic volumes corresponds to the common difference in the members of an homologous series. Thus a difference $n \times 22$ corresponds very closely to a difference of $n \times C_2H_2$. The atomic volumes of acetic acid $C_4H_4O_4$, propionic acid $C_6H_6O_4$, butyric acid $C_8H_8O_4$, and valerianic acid, $C_{10}H_{10}O_4$, are respectively 63·6, 85·4, 107·2, and 130·7.

Hydrogen may be replaced in a compound by an equivalent weight of oxygen without any essential alteration in the atomic volume. Alcohol $C_4H_6O_2$, and $C_4H_4O_4$, have respectively the atomic volumes 62·3 and 63·5. Chloride of ethyle C_4H_5Cl, and chloride of othyle $C_4H_3O_2Cl$, have respectively the atomic volumes 72·8 and 74·8. A slight increase on the atomic volume appears to be produced. Equivalent weights of carbon and hydrogen may replace each other without any essential alteration. Benzoic acid $C_{14}H_6O_4$, and butyrate of methyle

$C_{10}H_{10}O_4$, have respectively the atomic volumes 126·9 and 126·5. Diethylaniline $C_{20}H_{15}N$, and Caprylamine $C_{16}H_{19}N$, respectively 190·5 and 190.

The atomic volume of a compound appears to depend not so much on the empirical formula but on the rational composition. The atomic volumes of many elements have been calculated, in order to deduce therefrom the atomic volumes of the compounds which they constitute. It appears that to certain elements the same atomic volumes must be always ascribed; thus, carbon is always 5·5, hydrogen also 5·5, chlorine 22·8, iodine 37·5, while other elements appear to have various atomic volumes; their atomic volume appearing to depend on the place which the element occupies in the compound. Oxygen, for example, when it is contained *within* a compound radical has the atomic volume 6·1, and when *without* a radical the volume 3·9. Sulphur also, according as it is contained within or without a radical, possesses a different atomic volume.

For further information upon this subject the reader is referred to 'Kopp's Researches on Atomic Volumes' (Annalen der Physik u. Chemie, vols. xlvii., lii.; and Annalen der Chemie u. Pharmacie, vol. xxxvi); to Schröder on the same subject (Ann. der Physik u. Chemie, vols. l., lii.); to Filhol (Annales de Ch. et de Phys.. vol. xxi., third series); and to Messrs. Playfair and Joules 'Memoirs' (Chemical Memoirs, vols. ii., iii.; and Quarterly Journal of the Chemical Society, vol. i.).

ATOMS (from the Greek ἄτομοι, which is from ἀ and τέμνω, to cut), the ultimate and indivisible particles of matter. Some ascribe the origin of the idea to Moschus, a philosopher who lived before the Trojan war. Leucippus, a philosopher of Abdera, who flourished B.C. 428, is generally regarded as the original propounder of what is called *the Atomic philosophy*. It was adopted by Democritus, in his 'Cosmogony,' about B.C. 380, and afterwards by Epicurus, who died B.C. 270, to whom its celebrity is chiefly owing. Lucretius, who died B.C. 54, unites the tenets of Epicurus and Empedocles (B.C. 444) with the *infinite* of Anaximander (B.C. 550) and the *atoms* of Democritus. Dr. Whewell remarks, that the atomic doctrine was one of the most definite of the physical doctrines of the ancients, and was applied with most perseverance and knowledge to the explanation of phenomena; and that, although it led to no success of any consequence in ancient times, it served to transmit, through a long series of ages, a habit of really physical inquiry. The atomic doctrine, which we have mentioned, was opposed by the 'Homoiomeria' of Anaxagoras, who held that material things consist of particles which are homogeneous in each kind of body, but various in different kinds: thus, for example, since by food the flesh, bones, &c., of animals increase, there are in food particles of flesh, bones, &c. As the theory of Leucippus points to the corpuscular theories of modern times, so that of Anaxagoras may be considered as a glimpse of the idea of chemical analysis.

All matter may be conceived to be divisible *ad infinitum*, for we must suppose every particle to have an upper and an under surface, and these may be conceived as separated. Still, chemical analysis seems evidently to show that there is a limit set by nature to division, beyond which no natural powers can subdivide. [ATOMIC THEORY.] Hence, in physics, an atom is called *simple* when it cannot be further divided without separating its chemical elements. Thus, the dark spot on a soap-bubble, just before it bursts, cannot exceed $\frac{1}{3000000}$th of an inch in thickness; yet even this is not composed of a single stratum of atoms, for it must consist at least of one atom of soap and one of water; the former composed of soda, stearic, margaric, and oleic acids, and the latter of at least one molecule of oxygen and one of hydrogen, and each of these possessing the *essential* properties of impenetrability, extension, and figure.

We proceed now very briefly to sketch the general theory, which we have mentioned, of the atomic doctrine. According to Epicurus, every visible form is made up from matter and space (*corpus* and *inane*), which are equally infinite and unbounded, as well as eternal, and are opposite to one another in every respect. Thus, the solid parts of bodies are matter, and their pores space. Before the formation of the universe, in the state of chaos, these two principles were uncombined, and *atoms* existed floating about in the immense void. These are perfectly solid, indivisible, infinitesimal, infinite in number, and eternal. They possess however various shapes, as round, square, jagged, barbed, &c., though the number of these figures is not infinite. All solids contain more than one kind of figure, for they are formed by the impact of atoms floating downwards and being driven against one another; for the atoms, being all possessed of weight, fall downwards, and being by some cause diverted from their line of motion, impinge, and, according to the force of impact, form dense or rare bodies. This motion is eternal, and some do not impinge, but float about like specks in the sunbeams. They are also supposed to be destitute of heat, cold, and similar affections. These atoms, by their concurrence, produce all the different forms which we see; in fact, the world itself was formed by this fortuitous concourse of atoms, and is continually sustained by fresh tides of atoms flying through all space, and taking the posts of those perpetually flying off. Yet nothing is eternal and immutable but these seeds or atoms themselves. The world itself will be decomposed into its ultimate atoms, and new worlds will arise from its destruction.

ATONEMENT, a certain mode of appeasing anger, and obtaining pardon for an offence. In the act of atonement there is commonly understood to be a substitution of something offered, or of some personal suffering, for a penalty which would otherwise be exacted. The word is, indeed, applied colloquially to any circumstance of suffering, voluntary or involuntary, consequent upon criminal conduct or error of judgment. Thus even the spendthrift is said to have atoned for his folly by the hardships endured in consequence of it, and the murderer for his crime by a public death. But this use of the word is altogether indefensible. In theology, it has respect to offences committed against the Deity; it is in the theological acceptation of the term that it will be considered in the present article. The subject in this view of it is partly connected with that of sacrifice [SACRIFICE]; but it is not identical with it. For it is not certain that all sacrifices had atonement for their object; and sacrifice, as commonly understood, was only one amongst other methods of atonement.

The practice of atonement is remarkable for its antiquity and universality, proved by the earliest records that have come down to us of all nations, and by the testimony of ancient and modern travellers. In the oldest books of the Hebrew Scriptures, without noticing those earlier sacrifices the object of which may be considered doubtful, we have numerous instances of expiatory rites where atonement is the prominent feature, occupying, in fact, a large portion of the four last books of the Pentateuch. In some cases the atonement was made for a specific offence (Levit. iv., Numb. xvi. 46); in others it had reference to a state of transgression, as especially in the case of the scape-goat, on the day of expiation. (Levit. xvi.) The orthodox Jews of modern times have substituted a cock, which is killed and eaten with certain ceremonies. The offender again either atoned by his own personal act, or received the benefit of atonement by the act of another. (Levit. iv.) The Hebrew records contain also notices of the practice of atonement, independent of the Mosaic institutions, and unconnected with the religious opinions of the Hebrew people. The barbarous offerings to Moloch appear in the light of atonements when interpreted by the indignant expostulation of Micah (vi. 7)—"Shall I give my first-born for my transgression, the fruit of my body for the sin of my soul?" When Job is described (i. 5) as offering burnt offerings according to the number of his sons, and accompanying the act with the explanation, "It may be that my sons have sinned, and cursed God in their hearts," we are sure that the author of the book, and those for whom he wrote, were familiar with the notion of atonement.

But the atonement of Christianity is of a different character from any of these. It presupposes a state of sin or transgression, but it does not transfer the sin to an involuntary or unwitting substitute. In the Mosaic directions for atonement the means were generally symbolical of Christ, upon whose coming the former methods wholly ceased, and He became a self-sacrificed and willing means—and the only means—for the atonement of mankind with an offended creator. We can here do little more than state what is understood by the Christian when he speaks of the atonement. He does not consider man, according to the heathen notion mentioned below, to be the object of a capricious and vengeful enmity, but through a sinful nature, and practices and affections conformable to that nature, to have come into a state of alienation from God; in other words, he believes that God is just and holy, that man has sinned, and must therefore be punished. This being his condition, he further believes that the Divine Being, revealed to us under the title of the Son of God, interposed between the sentence and its execution, suffered in our stead, and atoned by His death for our sin; that the immediate consequences were, remission of the original sentence, and restoration to a state which is still probationary, but in which man is made capable of a permanent reunion with his Maker. The believer in the doctrine of the atonement supposes that the sacrifice was necessary according to a law fixed in the counsels of God (which law he also supposes to be revealed to us) that sin must be atoned for before it can be pardoned; but he distinguishes between the necessity of the sacrifice itself, and the further purpose of God in causing it to be publicly made, and providing that it should be universally known. He supposes the knowledge of the fact to be necessary to the formation of the Christian character, and its moral consequences to be, a deeper sense of the turpitude of sin; whereas there might otherwise be danger lest that should be lightly accounted of which appeared to have been lightly forgiven; and also a new and powerful motive to a love of the Supreme Being, supplying a remedy for that selfish principle which might prevail, if the only motives to obedience were the hope of reward and the fear of punishment.

We have endeavoured to state the doctrine of the Atonement in such terms as would be accepted by all, who accepted the doctrine itself on the authority of Scripture. It is well known, however, that among those who would concur in the general statement, there would be found minor differences of opinion, particularly as to the universality of the benefit conferred by the sacrifice. [CALVIN, in BIOG. DIV.] We have also without qualification called the doctrine in question a doctrine of the Christian religion; though we are well aware that there are some whose views of the gospel dispensation and whose interpretation of scripture have led them, whilst fully admitting the divine origin of our religion, to reject as unscriptural the doctrine of the atonement. But these would themselves readily acknowledge, we believe, that they are comparatively few in number.

To atone, according to the vulgar etymology, is to set at one, that is, to reconcile; and hence atonement is etymologically explained at-one-ment. Whether this derivation is right or not, reconciliation seems to have been the primary meaning of atonement with our earlier writers. Hence in the authorised version of the New Testament the same word which in 2 Cor. v. 19, is properly rendered reconciliation, is in Rom. v. 11, rendered atonement. The word, however, soon came to bear the meaning in which it is now used; and such is in fact its ordinary meaning in the authorised version of the Old Testament.

Among the heathen nations the doctrine of atonement was not unfamiliar. At the earliest date to which we can carry our inquiries by means of the heathen records, we meet with the same notion of atonement, with a distinction also in the application, between the removal of anger incurred by particular offences, and of that which was supposed to belong to the jealous character of the Deity. An instance of atonement of the former kind meets us in the very opening of the Iliad. Agamemnon having offended Apollo in the person of his priest, by refusing a ransom for his daughter, is not content with restitution, but proceeds to atone for his fault by an offering, the purpose of which is declared by Ulysses ('Il.' i. 442)—"Agamemnon sent me to sacrifice a sacred hecatomb to Apollo in behalf of the Danai, that we may appease the Sovereign God."

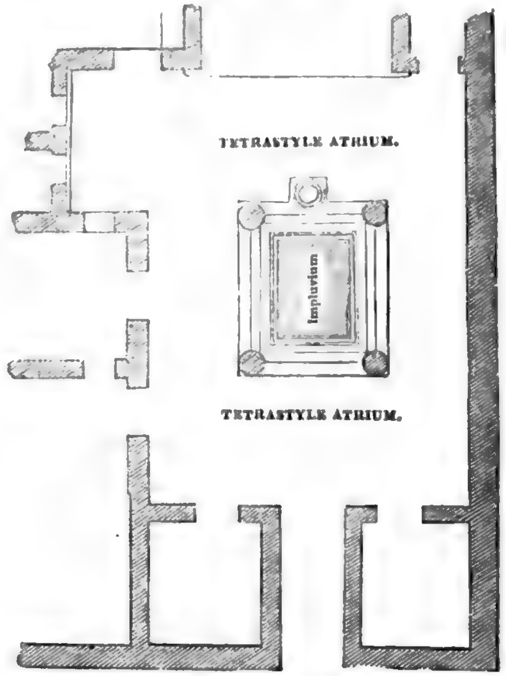
Among the many other instances which will readily occur to a reader of the ancient classics, the sacrifice of Iphigeneia by her father, to appease the wrath of Diana, is distinguished by the remarkable circumstance of the substitution of one victim for another by the offended goddess. It should be observed, however, that although the subject of the legend belongs to the period of the Trojan war, the legend itself is of a later date than the Homeric poems. In the expiatory rites for certain cases of homicide, sacrificial offerings to the deity formed a part of the religious ceremony of purification, in addition to the penalty which the offender paid as a compensation to the avenging party. A singular instance of atonement made to the Diana Orthia of the Lacedæmonians is given by Pausanias (iii. 16). Blood having been shed in a quarrel during a solemn sacrifice to the goddess, human victims were regularly offered to her as an atonement for the offence; till Lycurgus substituted for this cruel ceremony the scourging of youths at the altar with such severity, that the penalty was still paid with blood.

The practice of *general* atonement among the heathen nations, whatever may have been its origin, must have been greatly encouraged by a certain article in the popular creed, which is probably expressed pretty accurately by the saying put into the mouth of Solon by Herodotus, that 'the Deity is altogether a jealous being, and fond of troubling the even course of affairs' (*φθονερὸν τε καὶ ταραχῶδες*, Herod. i. 32). The common notion is remarkably exemplified in a story told by the same historian. Amasis, king of Egypt, having heard rumours of the marvellous and uninterrupted successes of his friend Polycrates, the sovereign of Samos, gave vent to his anxiety on his friend's account in a letter, which is in itself so curious, and so strongly illustrates the matter in hand, that we think it deserves to be presented entire to the reader. "Amasis says thus to Polycrates :—It is pleasant to hear that one's friend prospers ; yet your exceeding good fortunes please me not, knowing as I do that the Deity is a jealous being; and I could wish that both myself and those whom I care for should be fortunate in some of their doings, and in others miscarry; and so pass their lives in changes of fortune, rather than be always fortunate; for I never yet heard talk of any one who with good fortune in everything did not come to his end miserably with an utter downfall. Do you therefore follow my advice, and in respect of your happy chances do as I tell you. Look out well for the most precious thing you have, and that which you would most take to heart the loss of, and then away with it, in such sort that it shall never more come before the eyes of men. And if after this your successes should not take turns and go evenly with your mishaps, still remedy the matter in the way proposed by me." (Herod. iii. 40.) The story goes on to say that Polycrates took the advice of his friend, and flung into the sea a valuable ring; but the object was defeated by an incredible piece of good fortune, which restored to him his lost treasure. Hereupon Amasis formally dissolved his connection with a man so evidently marked out for some signal calamity.

In this case the offence was involuntary; yet it was not the less supposed to excite anger and expose the offender to punishment. Here too is an instance of atonement unaccompanied by sacrifice. The mode, indeed, of atoning admitted an almost infinite variety. Even the repetition on a certain occasion of the great games at Rome was strictly an act of atonement for a rather singular offence described by Livy, lib. ii. c. 36.

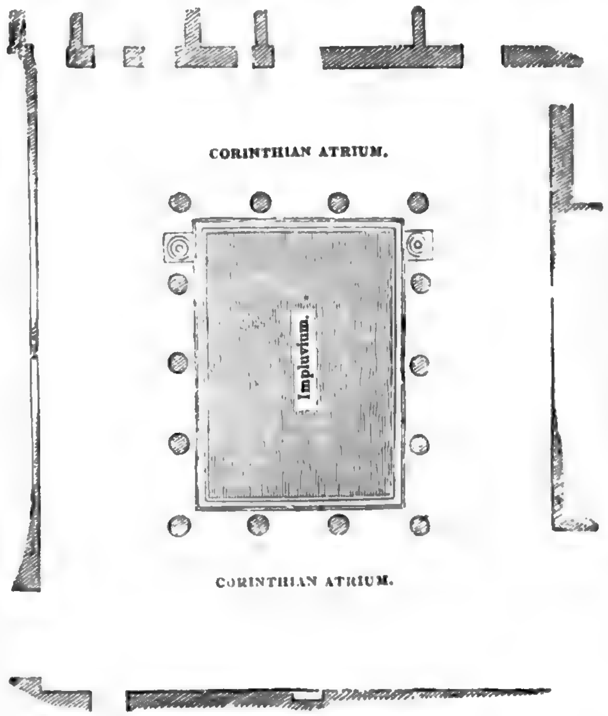
If we pursue our inquiries through the accounts left us by the Greek and Roman writers of the barbarous nations with which they were acquainted, from India to Britain, we shall find the same notion and similar practices of atonement. From the most popular portion of own literature, our narratives of voyages and travels, every one probably, who reads at all, will be able to find for himself abundant proof that the notion has been as permanent as it is universal. It shows itself among the various tribes of Africa, the islanders of the South Seas, and even that most peculiar race, the natives of Australia, either in the shape of some offering, or some mutilation of the person. We should expect to meet with it in India, so fertile in every form of superstition; and it is certain that many of the fantastic and revolting rites of the Hindoos bear testimony to its presence. The favourite practice of torturing the body has often there a different object, that of acquiring the reality or the fame of superior sanctity; but undoubtedly it is also resorted to as a mode of atonement.

A'TRIUM, a hall or room of audience in a Roman house. The two words, Atrium and Cavædium, if not at first synonymous, most probably became so in the course of time; Bekker, however, and some other authorities, consider that they mean different apartments. It appears from a passage in Varro, that the Cavædium, or Cavum Ædium, 'the hollow of the house,' must be the whole area between



Plan of a Tetrastyle Atrium from a house at Pompeii.

the rim of the compluvium from which the rain fell, and the impluvium into which the rain fell. The Atrium, properly so called, and as at first distinguished from the Cavædium, would be the space between the open area and the walls (*parietes*) of the Atrium : thus, the Cavum



Plan of the Corinthian Atrium of the villa of Diomedes at Pompeii.

Ædium would be the hollow space open to the sky and rain, while the Atrium would be the covered part, and would therefore form the hall or room of audience. If our conjectures, founded on this obscure passage of Varro, descriptive of the parts of a Roman house, be correct, we would suggest that the compluvium means rather the rim or gutter from which the rain fell [HOUSE, ROMAN] than the whole area of the open space over the impluvium.

The term Atrium is derived, according to Varro ('Ling. Lat.' iv.), from the Atriates, a people of Tuscany, from whom the pattern of it was taken. It was the most important and usually the most splendid apartment of a Roman house. Here the owner received his crowd of morning visitors, who were not admitted to the inner apartments. Originally the Atrium was the common room of resort for the whole family—the place of their domestic occupations; and such it probably continued in the humbler ranks of life. It consisted of a large apartment roofed over, but with an opening in the centre, called *compluvium*, towards which the roof sloped so as to throw the rain-water into a cistern in the floor called *impluvium*. Vitruvius distinguishes five species of Atria.

1. Tuscanicum, or Tuscan Atrium, the oldest and simplest of all. It was merely an apartment, the roof of which was supported by four beams crossing each other at right angles, the included space forming the compluvium. Many of these remain at Pompeii.

2. The Tetrastyle, or four-columned Atrium, resembled the Tuscan, except that the girders, or main beams of the roof, were supported by pillars, placed at the four angles of the impluvium. This furnished means of increasing the size of the apartment.

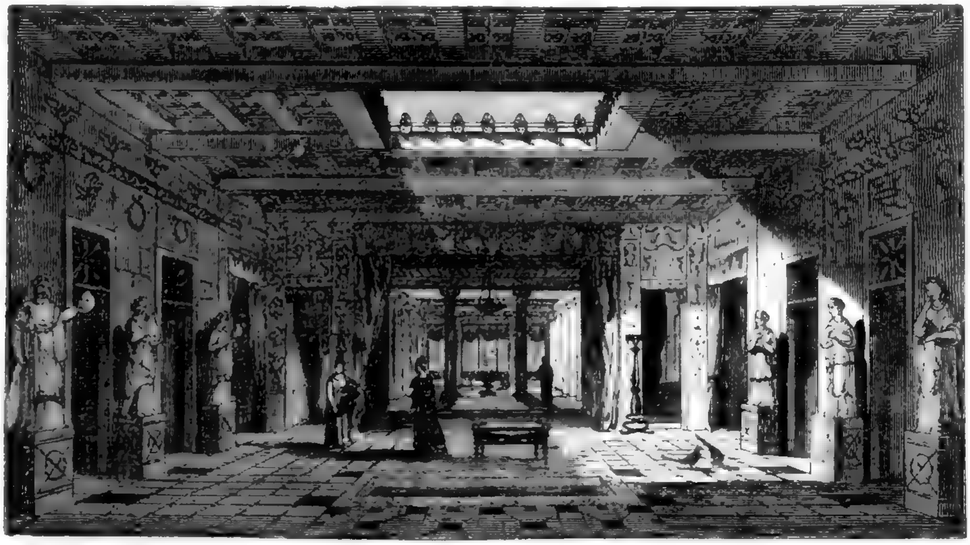
3. The Corinthian Atrium differed from the Tetrastyle only in the number of columns and size of the impluvium. A greater proportion of the roof seems to have been left open.

4. Atrium displuviatum had its roof inclined the contrary way, so as to throw the water off to the outside of the house, instead of carrying it into the impluvium.

5. The Atrium testudinatum was roofed all over, without any vacancy, or compluvium. ('Pompeii,' vol. ii.)

The magnificence of the Atria will be better understood from the annexed representation of the Atrium of the house of Pansa, restored by Mr. Gandy Deering, and published in the second volume of the 'Pompeii,' in the series of the 'Library of Entertaining Knowledge.' The walls (*parietes*) were painted with elegant designs in the style of arabesque painting [ARABESQUE], often surrounding compartments in which were frequently depicted the most celebrated subjects of ancient mythology, and even on the very floors mythological or historical pictures were executed in mosaic. [MOSAIC.]

For the details of the Atria of Pompeii we must refer the reader to Mazois' 'Antiquités de Pompéi,' folio, and to the first and second series of Gell's 'Pompeii,' as well as to the volumes on 'Pompeii' published by the Society for the Diffusion of Useful Knowledge. In the Pompeian Court at the Crystal Palace, Sydenham, there is a very careful restoration of a Pompeian house, which will give a much better idea of the Roman Atrium, with its connected apartments, than can possibly be obtained from engravings or a description.



Atrium of the House of Pansa.

ATROPA BELLADONNA, *Medical uses of*. This species is admitted into the Pharmacopœias of this country, and is employed in the form of dried leaves, or of an extract. Its action on the human system differs according to the quantity taken. If the dose be small, a quickening of the heart's action follows, and an increased quantity of blood is sent to the brain. In this case it has a stimulating effect; but if the dose be larger, though some stimulating action is for a short time apparent, a sedative effect of a very powerful kind ensues. During the first stage, excitement of the heart, the brain, and the intellectual faculties, is manifest; this is succeeded by greatly diminished sensibility, perhaps most markedly observable in the extreme dilatation of the pupil, and the insensibility of the stomach to the stimulus of emetic substances. The spinal cord would appear not to be directly influenced by this agent, but to suffer at last from the impaired state of the function of respiration, and the consequently deteriorated condition of the blood. Convulsions, therefore, only occur late in cases of poisoning by this article. It deserves to be remarked, that the delirium accompanying the action of an overdose of belladonna is always of a gay, elevated kind; a red eruption, or efflorescence, on the skin is also generally observable. The nausea and vomiting are unaccompanied with much pain of the stomach; nor do the stomach and intestines present many traces of inflammatory action. The nausea and vomiting seem to be the result of the condition of the circulation in the brain, the gorged state of the vessels of which is rendered obvious by inspection after death.

The action of belladonna is ascribed to an alkaloid which it contains, called *atropia*, which exists in combination with malic acid.

The cases in which belladonna may be advantageously employed are, diseases of increased sensibility of the nerves, particularly local affections of these, such as tic douloureux and other pains. It has also been recommended for the cure of scrofulous and cancerous tumours, and is employed to dilate the pupil in certain states of diseases of the eye. In the first set of cases, it may be employed either internally or externally. In tic douloureux, given internally along with arsenious acid, it often affords speedy and lasting relief. In the passage of gall-stones through the gall-duct, or of stones from the kidney, applied externally over the painful part, it gives great ease.

Its employment in cases of scrofulous and cancerous enlargement of the glands is likewise either internal or external. That it relieves the pain attendant on such affections is unquestionable; but it cannot be used to effect the cure of these with safety. It undoubtedly changes the process of deposition throughout the whole body, and also in morbid structure, into one of absorption—as is proved by the diminished solidity and increased fluidity of the body, as observed in cases of poisoning by it, where the great quantity of fluids favours the decomposition of the bodies which have died from its influence, and in which putrefaction always takes place very soon. But an equal degree of benefit may be obtained from the employment of antimonial preparations, without the danger which attends the use of this plant.

Its employment in the form of extract rubbed over the eyelids, to dilate the pupil previous to the operation for cataract, is an usual step, but requires caution: the same remark is applicable to its use in the form of solution dropped into the eye during inflammation of the iris. In both these cases it is liable to be absorbed in too great a degree, and to cause alarming symptoms.

Belladonna has been recommended as a useful sedative in the latter stages of hooping-cough. But though it lessens the violence of the spasmodic action, the same degree of benefit may be obtained from hydrocyanic acid, without the liability of inducing that action of the vessels of the brain which ends in hydrocephalus. (See Golis on 'Hydrocephalus.') Belladonna has also been proposed as a preventive of scarlet fever; but it is by no means certain to ward off this disease, while it is almost sure to induce hydrocephalus, on which account its use is to be reprobated. Other preventive measures of a safer kind should therefore be had recourse to.

In case of poisoning by it, if taken into the stomach, the most immediate means should be employed to remove it. For this purpose the stomach-pump is best. Emetics can seldom excite the stomach to any expulsive action; in some instances, fourteen grains of tartrite of antimony have been given without any effect.

Vinegar should not be given so long as any of the belladonna remains in the stomach, as it heightens its power. Vinegar is useful, however, at a later period, in combating the secondary or depressing effects. [ANTIDOTES.]

Bleeding relieves the gorged state of the vessels of the head, from the continuance of which the chief danger is to be apprehended; it should therefore seldom be omitted.

Atropia, the most active alkaloid (if *Belladonium* be another) of the Deadly Nightshade, has been introduced into the Pharmacopœias, and into medical (chiefly surgical) practice, as a substitute for the extract. It possesses the advantage of more uniform strength, being a definite compound, and the dose can be more exactly adjusted. Its combinations are also valuable, particularly the hydrochlorate and sulphate. It admits also of being formed into a tincture, and an ointment. These require, on account of their potency, even greater care in their employment than belladonna, or the extract. The application of one belladonna plaster immediately after another, still more before the previous one has been removed, is fraught with danger. The mistaking the ripe berries of the Deadly Nightshade for black cherries is pardonable, but to confound them with mulberries is a proof of great ignorance or most culpable carelessness, as the mulberries have an irregular, almost warty, surface, while those of belladonna are smooth, somewhat resembling cherries.

A'TROPHY, from the Greek word ἀτροφία, signifying 'want of nourishment,' 'wasting;' deficient nutrition, either of a part or of the whole of the body.

Nutrition, one of the most characteristic of the vital functions by which the living is distinguished from the inorganic body, consists in the conversion of foreign particles into the proper substance of the living being. The exercise of every vital function is attended with a certain expenditure of the substance of the organ by which the function is carried on. To supply this waste a stream of new matter is always flowing through every organ, from which each takes up the quantity required to replace the quantity which it expends. There are thus two opposite sets of actions incessantly going on in the living body; processes of waste, and processes of supply. In the state of health there is an exact balance between these opposite actions. In every morbid condition of the system, this balance is more or less disturbed, in consequence of which the whole body, or particular parts of it, become either too little or too much nourished. The first state, from whatever cause it results, is called *atrophy;* the second, *hypertrophy*.

In considering the phenomena of disease, then, there is one obvious guide as to its seat. If it be attended with decided, steady, and progressive wasting, it must be seated in some organ of supply. For the wasting itself is not disease, but the result and sign of disease; it is never the primary event, and seldom even the second in succession; it is a phenomenon forming part of a train, its place often being low down in a long series; it is the first to become visible, the phenomena which precede it, and on which it depends, not being visible, and frequently requiring careful investigation to detect them.

Wasting may be either general or local—that of the whole body, or only a part of it; and this will depend entirely on the nature of the cause that produces it, according as it is a disturbing influence affecting the system, or only some individual organ.

1. Wasting may of course be produced without disease, by merely withholding the supply of nutritious food. Nutritious food is the only source from which the material can be derived for repairing the waste of the vital functions. If it be inadequate, every function will languish, and every organ waste, in a degree proportionate to the scantiness of the supply.

2. Among the diseases capable of producing wasting, the most important are those which have their primary seat in the organs of nutrition. The stomach and intestines are the organs which produce the first and the most essential changes on the aliment, by which it is converted into nutriment, and prepared for assimilation. If any cause render these organs incapable of performing their functions, the ordinary waste of the body cannot be repaired, and a general atrophy must inevitably follow. Yet it is remarkable that these organs may perform their functions so imperfectly as to produce a great degree of disturbance in the system, without necessarily occasioning any manifest wasting. People sometimes suffer severely during a long life from dyspepsia, in its manifold forms, without getting thin. The reason is, that though the food be not easily and healthfully digested, yet, in the midst of the disturbance, enough of it is converted into nutriment to supply the ordinary waste of the body. Organic disease, however,—that is, disease attended with a morbid change in the structure of an organ,—rapidly tells upon the system, producing a progressive and ultimately an extreme degree of emaciation; and occasionally a single attack of merely functional dyspepsia, lasting only a few days, will render the body manifestly thinner, and cause the loss of many pounds of weight.

3. Next to the diseases of the primary organs of digestion come the diseases of the organs which co-operate with the stomach and intestines in converting the aliment into nutriment; and more especially diseases of the pancreas and liver.

4. But the food, when digested, has a long course to travel before it reaches the blood. It must be taken up by the lacteal vessels, and carried through the mesenteric glands. [DIGESTION, NAT. HIST. DIV.] It is probable that these organs are not mere channels of communication between the stomach and intestines and the lungs, but that they effect some change upon the imperfectly-digested aliment as it passes through them. Certain it is, that disease of these organs powerfully influences the process of nutrition, and produces a great degree of wasting. Examples of this are but too abundant in infants and children, who are cut off in great numbers by diseases which, on examination of the body after death, are found to have their chief seat in these organs. [MARASMUS.]

5. Disease of the organs of assimilation interrupts nutrition just as effectually as disease in the primary organs of digestion. It is not until the digested aliment reaches the lungs that it is converted into blood. The lungs finish what the stomach begins; and the function of respiration is the completion of that of digestion. Anything that impairs the function of respiration must therefore necessarily impair that of nutrition, and produce a proportionate degree of wasting. The lungs have this peculiarity, that they are capable of what may be called progressive destruction, the obliteration of one part after another in successive portions. The parts obliterated of course cease to contribute their share to the conversion of the aliment into blood; but the parts not obliterated continue to do so pretty much as in the state of health. Hence it is possible to breathe with only one lung, or with only half a lung; and the flame of life may, for a short time, be barely kept alive by a portion of even half a lung. The consequence is that, in certain diseases of the lungs, emaciation is carried to the utmost extent which seems to be compatible with the maintenance of the smallest particle of life.

6. But the process of nutrition is not completed even after the aliment is converted into blood. There still remains what may be termed the function of appropriation. After their conversion into blood in the lungs, the new particles are returned to the left side of the heart, whence they are carried out to the system by the larger trunks of the arterial vessels. These tubes terminate in a system of vessels of extreme minuteness, called the arterial capillaries, which are the true appropriators of the new particles prepared for them in the lungs, the architects and masons of the system, by which the new particles are deposited in the room of the old in the respective organs, and by which the waste is repaired. If, then, the capillaries of the system fail to perform their duty, no matter what quantity or what quality of nutrient matter be brought to them, the function of nutrition is suspended, and the body wastes; and, in like manner, if the capillaries of any particular part fail, the nutrition of that particular part must be at an end, and consequently its bulk diminish.

7. It is chiefly in consequence of the disease of these capillary vessels, that acute diseases, such as inflammation and fever, are always attended with so great a degree of wasting, although there is always, combined with this, disturbance of the digestive functions; so that in acute diseases nutrition is interrupted in a two-fold mode, by diminished digestion, and by imperfect appropriation of what is digested.

8. But a due supply of nervous influence is as indispensable to nutrition as a due supply of arterial blood. Whenever, therefore, the capillary vessels do not receive their appropriate nervous stimulus, the parts to which they belong waste. Whatever injures the nerves in such a degree as to impair their functions, is invariably found to occasion atrophy. If the nerves which supply a part waste, that part immediately begins to diminish in bulk; if a part has been long wasted, the nerves distributed to it become so small that they can scarcely be traced. If the head of an unreduced dislocated bone press upon the large trunk of a nerve, the parts to which the nerve is distributed waste. If a poison capable of producing paralysis of the nerves, such as lead, be gradually and slowly introduced into the system, the body wastes; an example of which is seen in the atrophy commonly attendant on the disease termed the *colica pictorum*, the colic of painters. As will be fully shown hereafter, it is the organic, not the sentient, system of nerves that supplies the nervous influence indispensable to nutrition. Injury to the sentient system may indeed occasion atrophy, but it produces this effect indirectly; whereas injury of the organic system produces it directly, by arresting the nutritive functions: and accordingly, the degree of atrophy arising from diseases of the brain and spinal cord is always very much less than that which is consequent on destroyed or impaired function of the organic nerves.

9. Finally, cessation of function, from whatever cause, is manifestly and invariably followed by wasting of the organ in which the function had its seat. The gland that does not secrete diminishes in bulk; the nerve that does not receive and transmit impressions, or convey its wonted stimulus, wastes; and the muscle that does not contract, dwindles away; while increased exercise contributes exceedingly to the augmentation of its volume, as we see in the bulk of the blacksmith's arm, and in the leg of the opera-dancer. From the complete and long-continued cessation of action, the substance of organs is sometimes almost entirely removed; nothing remaining by which its original structure can be distinguished.

Such are the most obvious and common causes of wasting, the detection of which, it is obvious, must precede any rational treatment of the affection. It can be cured only by the application of the appropriate remedy to the morbid state of the organ or organs on which it depends. The detection of this state is sometimes difficult, and the removal of it when discovered often still more difficult. But when it depends only on functional derangement, or on such a kind and degree of organic disease as admits of cure, the physician who succeeds in discovering the cause will easily and surely remove the malady [HYPERTROPHY.]

ATROPINE, *Atropia, Daturine* ($C_{34}H_{23}NO_6$). A vegetable alkaloid discovered by Geiger and Hess in the juice of the deadly nightshade (*Atropa Belladonna*), and in which the well-known poisonous qualities of the plant reside. It is also found in the seeds of stramonium (*Datura Stramonium*), and may be obtained by treating the decoction of either plant with magnesia, and digesting the precipitate in alcohol, which dissolves the alkali in question. Brandes procured it also by adding sulphuric acid to the decoction, filtering the solution, super-saturating with potash, filtering again, dissolving the precipitate in boiling water, and crystallising the solution.

The crystals are long, transparent, colourless, brilliant needles. Atropine is nearly insoluble in cold water, moderately soluble in ether, and easily so in alcohol. It forms with acids peculiar salts, several of which readily crystallise. During the evaporation of a salt of atropine, so great a quantity of it is volatilised, that the vapour occasions an enlargement of the pupils of the eyes of those exposed to its influence, which continues for several hours. Brandes supposes that the atropine exists, in part at least, in the state of malate in the deadly nightshade. When atropine is heated in a solution of potash or soda, ammonia is abundantly evolved.

ATTACHMENT. An attachment is a kind of criminal process which Courts of Record are authorised to issue summarily upon a mere suggestion, or upon the personal knowledge of the judges, without indictment or information. This process is properly granted in cases of contempts, which all courts of record may, in the absence of specific regulation by statute, punish in a summary manner, according to their discretion. Thus, if a contempt be done in the presence of the court by a breach of the peace, an open defiance of its authority, or an interruption of its proceedings, the offender may at once be attached and committed, and afterwards punished to a reasonable extent at the discretion of the presiding judges. On the other hand, if it be suggested by a third person upon oath that one not present in court has committed an action which amounts to a contempt, the court will make a rule upon the offender to show cause why an attachment should not issue against him; or in flagrant and urgent cases, where an immediate remedy is necessary, will grant an attachment on the first complaint without any previous rule to show cause. In modern practice, attachments are chiefly employed in cases of constructive contempts, such as abuses of the administration of justice by magistrates or judges of inferior courts, for corruption or injustice by officers and ministers of the courts in refusing to execute lawful process, for doing it oppressively, corruptly, or extortionately, or for making false returns. Mal-practices in these respects, which bring discredit on the administration of justice, are for that reason construed to be contempt of the courts, and punishable as such by attachment. Upon a similar principle, attorneys, who are officers of the different courts in which they are admitted, may be punished by this summary mode of proceeding for any dishonest practice, for unjust or fraudulent conduct towards their clients, or for not obeying the orders of the court in delivering up papers, paying over money, &c. It is said by Hawkins ('Pleas of the Crown,' book ii. c. 22, s. 30), that barristers, "though not officers of any court, yet inasmuch as they have a special privilege to practise the law, and their misbehaviour tends to bring a disgrace upon the law itself, are punishable by attachment for any foul practice, as other ministers of justice are." Jurors also may be liable to attachment for constructive contempts in their ministerial capacity; for instance, for making default when lawfully summoned, for refusing to be sworn or to give any verdict, or for receiving a bribe or instructions from either of the parties in a suit to be tried by them. In early periods of the history of our law, jurors were sometimes attached for acts done in their deliberative or judicial capacity, as for giving verdicts against evidence or the direction of the court in matter of law. That giving a false verdict should be considered a contempt of court was not so unreasonable as it may at first appear to those acquainted only with the province of juries at the present day. In ancient times the jury were to all intents and purposes witnesses who were sworn to speak the truth (*verum dicere*); and if they gave a wilfully false verdict upon facts, they committed a similar kind of contempt to that of witnesses committing manifest perjury at the present day. Hawkins gives it as the inclination of his opinion, that a jury would be still liable to an attachment for giving a verdict wilfully against the direction of the court in point of law. The absence of an instance, however, in modern times of such a proceeding would afford a strong argument against its legality. Besides the contempts committed by parties and persons as above noticed, there are instances which it would be endless to enumerate, in which all persons may become liable to attachment for offences of this description. Thus, wilful perjury in the presence of the court, disrespectful words or conduct to the presiding judge, counterfeiting writs, refusing to pay money or perform acts according to the direction of an award entered into by rule of court, non-payment of costs taxed by the officer of the court in which a proceeding is pending, are all instances of contempts which subject the persons who commit them to the summary process of attachment.

Attachment of Privilege was a process by which attorneys or other officers, entitled to privilege in the courts to which they belong, might formerly enforce the appearance of another person in their respective courts to answer to an action, but this course of practice has been abolished.

ATTACHMENT, FOREIGN. This is a judicial proceeding, by means of which a creditor may obtain the security of the goods or other personal property of his debtor, in the hands of a third person, for the purpose, in the first instance, of enforcing the appearance of the debtor to answer to an action; and afterwards, upon his continued default, of obtaining the goods or property absolutely in satisfaction of the demand. The process in England is founded entirely upon local customs, and is an exception to the general law of the land, as it exists only in London, Bristol, Exeter, Lancaster, and a few other towns. Indeed, the name of the process may serve to demonstrate its foreign origin, as we find a similar mode of securing the payment of a debt by a proceeding against the debtor's goods in the hands of third persons, forms under different names, a part of the municipal laws of Scotland, Holland, and most European countries in which the civil law prevails. In Scotland this proceeding is called arrestment. In France, the process exists under the name of *saisie-arrêt*. ('Code de Procédure Civile,' I., liv. 5, tit. 7.)

The custom of foreign attachment in London differs in no material respect from the same custom in other parts of England; it is, however, much more commonly resorted to in the Lord Mayor's court of London, than in any other local courts.

The creditor, who is the plaintiff in the action, makes, in the first instance, an affidavit of his debt, which must have been contracted within the city of London or its liberties, and be actually due. An action is then commenced in the usual manner; the only parties named in the first instance being the creditor as plaintiff, and the debtor as defendant. A warrant then issues, or is supposed to issue, to the officer of the court, requiring him to summon the defendant; upon this warrant the officer returns that the defendant "has nothing within the city whereby he can be summoned, nor is to be found within the same," and then the attachment may be made. This return of *non est inventus* to the process against the defendant is of the very essence of the custom, and without it all the subsequent proceedings on the attachment would be invalid; in point of fact, however, where an attachment is intended, the officer never attempts to summon the defendant, or gives him any notice of the action, but merely makes his return to the warrant as a matter of course. After this return, a suggestion is made, or supposed to be made, by the plaintiff to the court, that some third person within the city has goods of the defendant's in his possession, or owes him debts, by which goods or debts, the plaintiff requires that the defendant may be *attached*, until he appears to answer to the action brought against him. The attachment is then effected by a notice or warning served by the officer of the court upon the third party, who is called the garnishee, from an old French word *garnier*, or *garniser* (to warn), from whence *garnisée*, or vulgarly, *garnishee* (the person warned), informing him that the goods, money, and effects of the defendant in his hands are attached to answer the plaintiff's action, and that he (the garnishee) is not to part with them without the leave of the court. After this warning, the effect of which is to secure the property in the hands of the garnishee, the process again returns, or in principle ought to return, to the defendant, who must be publicly called and make default on four successive court-days, before any further proceedings can be taken against his goods. In practice, however, no process is served upon the defendant either at this or any other stage of the proceeding; nor is he ever in fact called,—notice of the action or the attachment being, according to the present practice, never actually given to him. After the four court-days have elapsed, the garnishee may be summoned to show cause why judgment should not be given against him for the goods or debt formerly attached in his hands. He then either appears and pleads, or he makes default; if he makes default, and the subject of the attachment is money, or a debt ascertained, the judgment of the court is final in the first instance, and execution may be issued at once for the sum demanded. But where the subject of the attachment is goods, a formal appraisement is made under a precept from the court by two freemen, sworn for the purpose; and judgment given for the goods so appraised. It sometimes happens that the garnishee has removed the goods before appraisement; in which case the officer returns the fact to the court, and a jury is empanelled to inquire and assess their value; and thereupon judgment and execution follow for the sum so assessed. But before execution can in any case issue against the garnishee, the plaintiff is required to enter into a recognisance with two sureties, obliging himself to return the money or goods taken under the attachment, if the *defendant* appears in court within a year and a day, and disproves or avoids the debt, or shows that it did not arise within the city.

The above is the course of proceeding in the case of a judgment by default. Instead of following this course, however, the garnishee, who is commonly the banker, factor, or agent of the defendant, usually appears and pleads. As matter of defence, he may deny that any debt is due from himself to the defendant, or that he possesses any goods or money of his; he may also show that he has a lien upon the defendant's goods in his own right. The question thus raised between the plaintiff and the garnishee is then tried by a jury, and judgment is given upon their verdict, with or without appraisement, according to the nature of the property attached. It should here be remarked that, according to the custom, the goods can never be actually seized in execution under the attachment; if the garnishee refuse to deliver them, the only remedy of the plaintiff is to arrest him.

A difference of opinion prevails amongst mercantile men with respect to the utility of this proceeding. On the one side, it is said to be important, in a commercial community, to be readily able to apply the property of an absent debtor, wherever it may be found, to the payment of his creditor; and this, it is contended, is particularly advantageous in a city much frequented by foreigners for the purpose of trade, who may contract debts during their abode in England, and then remove themselves to foreign parts, beyond the reach of personal process: on the other hand, it is supposed to embarrass commercial operations, in consequence of the enormous power which it places in the hands of creditors—a creditor for 20*l.* being entitled, if he pleases, to attach property to the amount of 20,000*l.*, or any larger sum, which cannot be applied in discharge of any commercial engagements which the debtor may have formed, until the attachment is disposed of. The apprehension of this process is said to deter foreign merchants from consigning cargoes to London. It does not, however, appear to be likely that the existence of this custom should, under ordinary circumstances, have the effect of deterring the fair merchant from sending his goods to London; though it may well happen that a trader who has contracted debts in London which he does not intend to pay, or who suspects that claims will be set up which he does not wish to afford the claimants any facilities in litigating, would hesitate to send a cargo to a port where, by means of this process, any of his creditors there, real or pretended, might instantly seize it. Nor can much practical inconvenience arise from the power of attaching a large property for a small debt; for the garnishee, who is almost in all cases the agent of the defendant in some shape or other, may at any time dissolve the attachment, by appearing for the latter, and putting in bail to the action; or, if satisfied with the truth of the debt upon which the attachment issues, he may pay the plaintiff's demand, and take credit for the amount in his account with the defendant: for a payment under an attachment would be *pro tanto* an answer to any demand against the garnishee by the defendant. The alleged objections do not, therefore, appear to be so formidable as has been represented; but the advantage of a speedy and safe mode of recovering debts is obvious.

There are, however, many imperfections in this form of proceeding. No costs are recoverable on either side: and therefore where a small debt is contested, if the plaintiff succeeds against the garnishee, his costs may very possibly exceed the sum he can recover; and if the garnishee succeeds in showing himself not to be liable to the attachment, he may incur a considerable expense without the possibility of reimbursement. The efficiency of the custom is also much impeded by the limited extent of its local jurisdiction. Thus, goods in a warehouse in Thames-street may be attached; but if lying in a lighter on the river Thames within a yard of the warehouse, they are exempt. So also, if a merchant keep his cash with a banker in the city, it is liable to the process; but if his banker dwell a few yards beyond the limits of the city, no attachment can be made of his balance—unless indeed the plaintiff should prepare himself with process, and be fortunate enough to serve it upon one of the partners when accidentally within the jurisdiction; in which case, as he is supposed to carry with him all the debts and liabilities of the house to which he belongs, the balance of any customer of the firm might be attached.

Although the procedure of the Lord Mayor's court has been recently improved, the custom and practice of foreign attachment remain as they were. It may be added that when the legislature (Common Law Procedure Act, 1854) conferred on the Superior Courts of law powers of ordering the attachment of debts due to judgment debtors, and compelling their payment to the creditors *after judgment*, it refrained from giving any authority to do so as a preliminary step to an action, which is the nature of the process called foreign attachment, of arrestment in Scotland, and of *saisie-arrêt* in France, and in those countries where a similar procedure is in use. [GARNISHEE.]

ATTACK, or ASSAULT. Assault is taken from the French *Assaut*, which is derived from the Latin *Assilio, Assultum*, to leap against. This word, in military science, is applied to the attack made by a besieging army on a fortress or military post, or more generally to the attack of any strong position. When a regularly fortified place is besieged, the besiegers after pushing their approaches close to the defences, and making breaches in them, either by breaching batteries or by mines, give the assault, which, if successful, places them in possession of the portions of the works immediately about the breach, where they establish themselves by forming lodgments; or, as constantly happens, the attacking party, pushing on, seize the whole place. Such was the case at one of the most remarkable assaults in history, that of San Sebastian in August, 1813. The principal breach was in the sea-face which had been battered down for a length of about 500 feet. The assault was given in the morning, when the tide permitted the Uremea to be forded. For nearly two hours the desperate exertions of the storming parties were unsuccessful. Sir John Jones, in his 'Journals of Sieges,' note 36, says: "Had the struggle been merely that of man to man, the result would not have remained for many minutes doubtful; for the troops mounted the breach, and gained the summit at the first rush, in sufficient numbers and sufficiently formed to have borne down any body of men which could have been formed on the rampart to oppose them. The French foreseeing this had, with their usual skill, trusted their defence to artificial obstacles, which should prevent the assailants advancing beyond the crest of the breach, and to directing a most powerful and close fire on the summit, which was far too confined to admit of cover being established on it, to guard the assailants from the effects of missiles." The interior retaining wall of the rampart and the walls of the ruined houses in the neighbourhood were loop-holed, and had a banquette in rear, so as to obtain a heavy fire on the summit of the breach, while the circulation along the rampart was impeded by means of walls and traverses formed across the terrephin. The assailants, therefore, had either to force over these defences under a close fire, or jump down the retaining wall 24 feet in depth. General Graham, in his despatch to the Duke of Wellington, says: "Everything that the most determined bravery could attempt was repeatedly tried in vain by the troops, who were brought forward from the trenches in succession. No man outlived the attempt to gain the ridge; and though the slope of the breach afforded shelter from the enemy's musketry, yet still the nature of the stone rubbish prevented the great exertions of the engineers and working party from being able to form a lodgment for the troops." "In this almost desperate state of the attack, after consulting with Colonel Dickson, commanding the Royal Artillery, I ventured to order the guns to be turned against the curtain. A heavy fire of artillery was directed against it, passing a few feet only over the heads of our troops in the breach, and was kept up with a precision of practice beyond all example." A column of Portuguese now fording the river at the mouth, attacked and carried the right of the great breach, and a small breach on its right, whilst a British column, taking advantage of the admirable fire on the curtain, advanced again, and fortunately arriving at the breach just at the time when an explosion on the rampart of the curtain (occasioned by the fire of the artillery) created some confusion among the defenders, carried it; and the first column having forced their way into the adjoining houses, the town was gained. Nothing could restrain the impetuosity of the troops, the enemy were driven from their defences in the streets, and after suffering a severe loss, were forced to retreat into the castle, which surrendered after a few days' siege.

This assault is remarkable, not only for the severe contest maintained with unparalleled bravery on both sides, but also from the circumstance of a heavy fire of artillery from forty-seven guns having been directed on the summit of the breach over the heads of the storming party. It was also effected in daylight, a rather unusual circumstance. Sir John Jones says on this head: "daylight is certainly the best time for storming works when the troops can advance under cover to the breach or point of escalade, or have the support of a powerful artillery. But when the garrison have preserved an extensive front of fire, and the trenches have not been pushed very forward, to storm in daylight can be seldom advisable, as the troops would most frequently suffer so much in advancing as to be disabled from any serious effort when arrived at the breach. The most preferable time for such open advances is at the moment of day-break. In the dark the troops are liable to imaginary terrors, and being concealed from the view of their officers, the bravest only do their duty. When it is decided to assault a place immediately before day-break, the utmost attention should be given on the previous morning to ascertain the exact moment of its becoming light; and the most energetic and decided measures must be taken to insure the columns advancing at the instant fixed upon, as it will be equally prejudicial to their success to be too soon, as to be too late." The truth of these remarks was fully borne out by the assaults at the late siege of Sebastopol. In the assault of the 18th of June, which was intended to be given some hours after day-break, so as to allow the artillery to destroy any defences which might have been repaired in the night, the right French column appears to have lost its way, and becoming entangled with the Russian outposts, commenced the assault too soon. Though much before the concerted time, the main French column advanced to the assault of the Malakoff, and the English force had to be ordered forward on the Redan, to support these attacks. They were all unsuccessful. Not only was the garrison on the alert, and the artillerymen standing by their guns ready to pour grape into the heads of the columns immediately they appeared, but also they had, by incredible exertions during the night, repaired their defences and replaced their disabled guns. The fire on the assaulting columns was so severe that they were annihilated almost as soon as they issued from the trenches.

In the successful assault of the 8th of September, the French, rushing from their trenches close to the Malakoff, were in the works, which were not of a nature to offer any obstacle to such an effort, before the garrison could get to their posts. The resistance, however, with which the other French columns and the English column were received, when the defenders had been put on the alert by this attack which had preceded them only by a few minutes, was very different, insomuch that none of them were successful.

ATTAINDER, from the Latin word *attinctus*, "attaint," "stained," is a consequence which the law of England has attached to the passing of sentence of death upon a criminal. Attainder does not follow upon mere conviction of a capital offence; because, after conviction, the judgment may still be arrested, and the conviction itself cancelled, or the prisoner may obtain a pardon; in either of which cases no attainder ensues. But as soon as sentence of death is passed, or a judgment of outlawry given where the person accused flies from justice, which is equivalent to sentence of death, the prisoner becomes in contemplation of law *attaint*, stained, or blackened in reputation. He cannot sue or be a witness in a court of justice; he loses all power over his property, and is rendered incapable of performing any of the duties, or enjoying any of the privileges, of a freeman. The person of a man attainted is, however, not absolutely at the disposal of the crown. It is so for the ends of public justice, but for no other purpose. Until execution, his creditors have an interest in his person for securing their debts; and he himself, as long as he lives, is under the protection of the law. (Macdonald's case, Howell's 'State Trials,' vol. xviii. p. 862.)

We shall consider, first, the subject of attainder as it exists by the ordinary laws of the realm; and, secondly, give some account of those extraordinary enactments of the legislature, commonly known by the name of Bills of Attainder.

1. The principal consequences of attainder, according to the ordinary course of law, are forfeiture of the real and personal estates, and what is technically called corruption of the blood of the offender. The forfeiture of the personal estate dates from the time of his conviction, but extends only to the goods and chattels of which he was actually possessed at that time. Real estate is not forfeited until attainder; but then the forfeiture (except in the case of attainder upon outlawry) has relation to the time when the offence was committed, so as to avoid all intermediate sales and incumbrances. ('Co. Litt.' 390 b.)

The extent and nature of the forfeiture of real estate upon attainder differ in the case of high treason, and in cases of murder or other felony. Attainder for high treason is followed by an immediate and absolute forfeiture to the crown, of all freehold estates, whether of inheritance or otherwise, of which the person attainted was seised at the time of the treason committed. This consequence of attainder for high treason is said by Sir W. Blackstone to have been derived from Anglo-Saxon jurisprudence. Copyholds are in like manner forfeited to the lord of the manor of which they are holden, upon the attainder of the tenant.

By stat. 5 & 6 Edw. VI. c. 11, the dower of the widow of a person attainted for high-treason is also forfeited. But it is to be remembered that there is no forfeiture unless an actual attainder takes place; and therefore if a traitor dies before judgment, or is killed in open rebellion, or is put to death by martial law, his lands are not forfeited, unless a special Act of Parliament is passed for the purpose. It is said, however, that if the Chief Justice of England in person, upon the view of the body of one killed in open rebellion, records the facts and returns the record into the Court of King's Bench, both the lands and the goods of the rebel shall be forfeited.

This absolute and entire forfeiture of the estates of persons convicted of high treason, was often productive of extreme hardships and injustice, by making their families, who were no parties to their crimes, participate in their punishment. In what might be termed, while they existed as such, modern treasons, such as offences relating to the coin, it was expressly provided by the statutes creating them petty treason, that they should work no forfeiture of lands except for the life of the offender, and that they should not deprive his widow of her dower.

In cases of attainder for murder or other felony, the forfeiture of lands to the crown does not extend for a longer term than a year and a day, with an unlimited power of committing waste upon the lands during that period. This is called in our old law-books '*The King's year day and waste.*'

After the expiration of the king's year day and waste, the lands, instead of descending as they naturally would to the heir of the person attainted, were by the feudal law of escheat for corruption of blood, transferred or escheated to the lord of whom they were holden. In order to understand the doctrine of escheat for corruption of blood, we must remember, that, by the feudal law, from which our modern law of real property is chiefly derived, all lands were, or were supposed to be, held by gift from a superior lord, subject to certain services and conditions, upon neglect or breach of which (as well as upon failure of issue of the grantee) the lands reverted, or in feudal language, escheated, that is, fell back to the original giver. Now, by the attainder of a tenant in fee-simple for felony, the compact between him and his lord was totally dissolved; his blood was supposed to be corrupted, and he was disabled not only from inheriting lands himself, but from transmitting them to his descendants. Even though he had no lands in possession at the time of the attainder, and acquired none afterwards upon which the law of forfeiture could operate, the law of escheat might operate after his death to the prejudice of his descendants. For, owing to the corruption of his blood, which completely stopped up the course of descent, it was impossible to derive a title to any lands, either from him directly, or from a more remote ancestor through him. The inevitable consequence was an escheat to the lord. The practical injustice and hardship caused by the doctrine of the corruption of blood in punishing the offences of the guilty by a heavy punishment upon the innocent, frequently attracted the attention of the legislature; and it consequently became usual, where a new felony was created by Act of Parliament, to make an express provision that it should not extend to corruption of blood. By the statute 7 Anne, c. 21 (the operation of which was deferred by 17 Geo. II. c. 39), it was enacted, that after the death of the then Pretender and his sons, no attainder for treason should extend to the disinheriting any heir, nor the prejudice of any person other than the offender. But, both these statutes being repealed by 39 Geo. III. c. 93, the ancient law of forfeiture for treason was restored. By the statute 54 Geo. III. c. 145, corruption of blood was next taken away for attainder, except in cases of treason, petit treason (that is, where a wife had murdered her husband, a servant his master, or an ecclesiastic his superior), and other murders. Finally, the worst consequence of the doctrine of corruption of blood, namely, the impossibility of descents being traced through attainted persons, was removed by the statute 3 & 4 Wm. IV. c. 106, s. 10, which enacts, that no attainder for the future shall prevent descent from being traced through the attainted person.

A dignity descendible to the heirs general is forfeited to the crown both for treason and for felony. An entailed dignity is forfeited for treason, but not for felony. Thus Lawrence Earl Ferrers, whose peerage was limited to the heirs male of the body of his ancestor, being attainted for murder in the reign of Geo. II., was succeeded by Washington Earl Ferrers, his next brother.

The corruption of blood produced by attainder cannot be effectually removed except by authority of Parliament. "The king," says Blackstone, "may excuse the public punishment of an offender. He may remit a forfeiture in which the interest of the crown is alone concerned; but he cannot wipe away the corruption of blood; for therein a third person hath an interest, the lord, who claims by escheat." But it appears from the same author, that the king's pardon is so far effectual after an attainder, that it imparts new inheritable blood to the person attainted, so that his children born after the pardon may inherit from him.

2. Besides the modes of attainder by the common law, as above described, there have been frequent instances in the history of England, of attainders, by express legislative enactment, called bills of attainder. This has happened when, either from the extraordinary nature of the crime, or from unforeseen obstacles to the execution of the ordinary laws, it has been thought necessary to have recourse to the supreme power of the legislature, for the purpose of punishing particular offences. These enactments, either in the shape of bills of attainder or bills of pains and penalties, have been made at intervals from an early period of our history, down to very recent times. The moral justice, as well as the policy of these *ex post facto* laws, has been often questioned; and they have generally occurred in times of turbulence or of arbitrary government; but the number of them is sufficiently large to form a formidable list of precedents for any future suspension of the ordinary law. There were some instances of them under the Plantagenet princes, as the bills of attainder against Roger Mortimer and Edmund earl of Arundel, in the reign of Edward III. Both of these, however, were reversed in the same reign. It was not till the reign of Henry VIII., which was fertile in new crimes and extraordinary punishments, that the proceeding by bill of attainder became so common as almost to supersede trials according to the ordinary process of law. Scarcely a year passed without persons of the highest rank and most distinguished character being brought to the scaffold by bill of attainder. Among them were the celebrated earl of Surrey, Cromwell earl of Essex, who is said to have been the adviser of these measures, and most of those persons who suffered for denying the supremacy of the crown in matters ecclesiastical. All of these were attainted upon mere hearsay evidence; and some not only upon no evidence at all, but without being heard in their defence. In the following reign of Edward VI., the Protector Somerset encouraged a bill of attainder for treason against his brother Lord Seymour of Sudley, the lord high admiral of England and husband of the queen dowager Catharine Parr, which was hurried through both houses of Parliament, without the accused being permitted to say anything in his defence. But, as the nation became better acquainted with the principles of constitutional freedom, parliamentary attainders became less frequent. Under the Stuarts recourse was seldom had to this extraordinary mode of proceeding. It was thought necessary to adopt it in the time of James I., with respect to Catesby, Percy, and several other persons, who were killed in the insurrection that ensued upon the discovery of the Gunpowder Plot, or died before they could be brought to trial, as they, not having been tried, could not have been attainted by the ordinary process of law. It was again adopted by the Long Parliament in Lord Strafford's case, on the ground that he was an extraordinary criminal, who would have escaped comparatively uninjured, if no other penalties than those of the existing laws had been awarded against him. But even Lord Strafford's attainder was reversed after the restoration of Charles II., and all the records of the proceedings cancelled by Act of Parliament. The duke of Monmouth also, on his appearing openly in arms against the government, in 1685, was attainted by statute. A remarkable instance of a proceeding by bill of attainder occurred in the case of Sir John Fenwick, who, in the year 1696, was attainted for a conspiracy to assassinate William III. There is no question that Sir John Fenwick might have been tried by

the ordinary process of law. The excuse urged for resorting to a bill of attainder was, that there was no *moral* doubt of Fenwick's guilt; but that as two witnesses were required by the statute of 7 Will. III. c. 3, in order to convict him; and as one of them had been tampered with, and removed out of the kingdom, *legal* proof of an overt act of treason became impossible.

The effect of this bill of attainder was therefore to suspend the statute of 7 Will. III. c. 3, before it had been two years in operation, in order to destroy an individual. This questionable exertion of legislative power did not take place without a strong opposition, and has been frequently reprobated in subsequent times. Bishop Burnet, one of its most strenuous supporters, allowed that "this extreme way of proceeding was to be put in practice but seldom, and upon great occasions." (Howell's 'State Trials,' vol. xii.)

The legislature, acting in conformity with this sentiment, have seldom, since the accession of the House of Hanover, had recourse either to Bills of Attainder, or Bills of Pains and Penalties. One instance of a departure from this principle occurred during the Irish Rebellion, in 1798, in the case of Lord Edward Fitzgerald, who being arrested on a charge of high treason, and dying in prison before he could be brought to trial, of the wounds which he had received in resisting his apprehension, was attainted by Act of Parliament. But when the violence of party spirit had subsided, the old principle of the constitution, that every man shall be considered innocent of a crime until his guilt has been legally proved, prevailed, and a few years ago the attainder was reversed. There is little reason to apprehend that a practice so obviously unjust, and so dangerous to the fundamental principles of good government, will be adopted in future.

Of late years, the forfeitures resulting from the numerous attainders consequent on the rebellions in 1715 and 1745, have been relieved by acts of grace, and many persons thus enabled to claim and obtain a restitution of their hereditary honours. (M'Queen's 'Reports,' vol. i. p. 786.)

ATTAINT (*attincta*), an old writ, which formerly lay to inquire whether a jury had, or had not, given a false verdict. It at first lay only on the trial of writs of assize, and is said to have been introduced by Henry II., at the instance of Chief Justice Glanville, as a check on the vast power then vested in the recognitors of assize of finding a verdict according to their own personal knowledge, without an examination of witnesses. It was afterwards extended by Edward I. to all pleas of land or freehold, and by statutes in the reigns of Edward I. and Edward III., to all pleas whatsoever, whether real or personal, except writs of right, where the issue was joined on the *mere right*.

The grand jury on the attaint were twenty-four in number, and if they found that the verdict was false, the judgment against the petit jury that had found it was one of extreme severity: namely, to lose their *liberam legem* and be infamous, to forfeit their goods and profits of their lands, to be imprisoned, and their wives and children to be thrown out of doors; their houses to be rased, their trees extirpated, and their meadows ploughed, and the plaintiff to be restored to all he had lost by reason of the unjust verdict. But as this severity had the actual effect of preventing the law from being executed, a much more moderate judgment was afterwards introduced by 11 Henry VII. c. 24, made perpetual by 13 Eliz. c. 25.

This clumsy expedient for controlling the extensive power of a jury was one, however, which could only with great difficulty, and in rare cases, be carried into operation. The jury could only be attainted on the same evidence as that given before them; and either for finding a verdict contrary to that evidence, or for finding one on evidence not sustaining the issue. It was almost impossible to attaint them on the former ground, since they were at liberty to take their own personal knowledge for evidence; as to the latter, the judge had some control over the jury, by giving them directions as to the precise point of the issue to which the evidence was to be applied; and if they found a verdict contrary to the express direction of the judge, they certainly ran great risk of an attaint. So inconvenient and ineffectual, however, was the proceeding, that it gave place, in the time of Elizabeth and James I., to the now existing practice of setting aside verdicts on motion and granting new trials; and very few instances of an attaint appear in the books later than the sixteenth century. By the 6 Geo. IV. c. 50 (consolidating the laws relating to juries) the writ of attaint was abolished; but corrupt jurors may be proceeded against by indictment or information, and punished accordingly. [EMBRACERY.]

(*Blackst.* 'Comm.' Mr Kerr's ed. vol. iii. pp. 377, 418, 438.)

ATTAR, or OTTO OF ROSES, an essential oil obtained in India from the petals of the *Rosa centifolia* and *sempervirens*; for this purpose a cask or glazed earthen jar is filled with the rose leaves carefully separated from the calyxes, and spring water poured in just sufficient to cover them: the vessel with its contents is then set in the sun for two or three days, and taken under cover during the night. At the end of the third or fourth day, small particles of yellow oil will be seen floating on the surface of the water, which in the course of a week will have increased to a thin scum; this is taken up by a little cotton tied to the end of a stick, and squeezed into a small vial. (*Aitkin*, 'Dictionary of Chemistry.')

The attar is now more frequently made by distilling rose leaves with water. At first the attar dissolves in the distillate, but by returning the latter upon fresh quantities of leaves, the attar distils in larger quantity than can be dissolved by the water which comes over with it, and it then forms an oily layer which is removed; the water being again used for the next distillation.

This oil is a well-known perfume; but the odour is agreeable only when diffused, being too powerful when it is concentrated. According to Saussure, the attar is a mixture of two oils, one of which is solid and the other fluid, at the usual temperature of the air: they may be separated by washing with alcohol, which does not dissolve the concrete oil at a low temperature; or by pressure between folds of paper, which absorbs the fluid oil. By the latter process, three parts of the common yielded one part of the concrete oil.

Attar of roses liquefies at about 85° of Fahrenheit, and the solid oil at about 91°; the latter crystallises by cold into brilliant white transparent laminæ of the consistence of bees' wax. The density of attar of roses rendered fluid at about 90°, compared with water at 60°, is 0·832, which, according to M. Saussure, is less than that of any other essential oil that he examined; the concrete oil, when fused, is even lighter than this.

The concrete essence is very slightly soluble in alcohol, 1000 parts of the density of 0·806, taking up only two parts of it at 57° Fahrenheit, while the same quantity of alcohol dissolves seven parts of the attar, and the fluid portion is still more soluble.

Saussure observes that the concrete oil burns in oxygen gas with a sort of explosion, which he has never observed to so high a degree in any other oil. By analysis the attar was found to consist of

Carbon	86·743
Hydrogen	14·889
	101·632

Saussure observes that the most remarkable circumstance attendant upon this analysis, is its close resemblance to that of olefiant gas, which consists of carbon 85·71; hydrogen 14·29.

ATTENDANT TERM. [TERM OF YEARS.]

ATTIC, a term in architecture, comprehending the whole of a plain or decorated parapet wall, terminating the upper part of the façade of an edifice. The derivation of the word is uncertain. It appears to have been a generally received opinion that the word was derived from the circumstance of edifices in Attica being built after this manner. There is at Athens a monument, that of Thrasyllus, with an attic over the order of pilasters which form the basement. In the centre there was a colossal statue. In a note to the second edition of Stuart's

Upper part of the Façade of the Monument of Thrasyllus, with the seated figure restored, from the original in the British Museum.

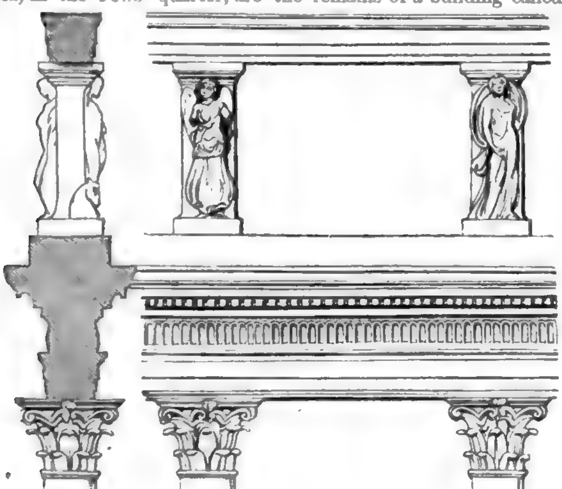
'Athens,' published in 1825, the editor is of opinion that this attic was not contemplated in the original design, but added at the date of the two upper inscriptions when Thrasycles was Agonothetes. (See note, p. 92, vol. ii., second edition of Stuart, 1825.) This example however may be taken as the best type of a Greek attic which is at present known. In the 'Archaiologia Londinensis' there is an ingenious, although, as we think, a wrong derivation of the word attic, unless we suppose the word, as we now use it, to have become corrupted. In vol. xxiii. pp. 412–14, the word attic is said to be compounded of *a* privative, and τεῖχος, a wall, thus signifying "without a wall, or without being in connection with a wall." The example of such an attic, it is said, is found in all Hypæthral temples, for as the naos, nave or space between the inner ranges of the columns, must not be covered, upper ranges of columns, with a wall above them, must be placed over the lower order of columns to catch the end of the rafter at its highest elevation: an example of this kind of attic may be found at Pæstum, in Italy.

Another example, which bears a closer resemblance to the Roman attic, exists in the upper wall of the nave of the Temple of Jupiter Olympius at Agrigentum [ATLANTES], where there is an entire wall with short pilasters at intervals, in the front of which are figures placed above the pilasters of the nave. Vitruvius and Pliny do not make any mention of or allusion to the attic of a building as we understand it at the present day. In the annexed cut we have given a representation of a Roman attic, the only remaining part of a superbly decorated wall

Part of a Building inclosing the Forum of Nerva at Rome.

inclosing the Forum of Nerva at Rome. This wall was of considerable extent, and was divided at intervals by columns projecting from the wall, over which, as may be seen in the drawing, the attic wall is continued at right angles to the wall forming the inclosure. The attic also is a very conspicuous feature in the triumphal arches at Rome, and a necessary one; it was not merely intended as a frame-work for the inscription, nor as a support for statues, but is essential to the proportions of the whole composition. [ARCH, TRIUMPHAL.]

In all the best examples, and especially in the remains of antiquity at Rome, the attic is decorated with a moulded base and cornice, often with pilasters and figures, as in the arch of Constantine. At Thessalonica, in the Jews' quarter, are the remains of a building called the



The Incantada at Thessalonica.

Incantada, drawn and described by Stuart in the 3rd vol. of his 'Athens.' Five Corinthian columns on their pedestals support an entablature: over four of these columns there still exists an attic adorned on each side with figures in alto-rilievo. The spaces between the figures are open, and there is a cornice over the figures with a base at their feet. The design and execution of this work are attributed to the period of Roman dominion, rather than to any other. (Stuart's 'Athens,' vol. iii.) At Bourdeaux, a somewhat similar building existed in the reign of Louis XIV., which was destroyed by Vauban to erect the fortifications constructed at that time. Perrault, the architect, made a drawing of the ruin previous to its destruction, from which circumstance the design is now preserved, and may be seen in the 2nd edition of Stuart's 'Athens' (1825). The most remarkable difference between this building and the Incantada is, that in the former the openings in the attic between the figures are arched, while in the latter they are bounded by the straight line of the cornice. The arch in the former proves it incontestably to have been a Roman work; while from the uncertainty respecting the date and use of the building at Thessalonica, the period of its erection cannot be ascertained.

The Italian architects who had studied the remains of antiquity in Rome, and those who followed in their school, usually employed an attic in their designs, as may be seen by a reference to their works, and more especially to the designs of Palladio, entitled 'Le Fabbriche e i disegni di Andrea Palladio raccolti ed illustrati,' da Ottavio Bertotti Scamozzi, 1776. The attic is in very common use in the public buildings of London. Somerset House, in the view towards the street, may be taken as offering a very good example of this feature of an edifice. Opinions differ as to the attic: some consider it a deformity, and at least only to be tolerated where it is unavoidable. They would accordingly confine it nearly altogether to domestic architecture.

ATTIC, IN BUILDING. Generally speaking, in England the term attic is limited to the sense of a story in the roof of a building; and it is even applied to such stories, when there is a decoration, such as a balustrade or parapet, which completes the elevation and effectually masks the roof itself.

The rules usually observed by architects in settling the proportions, and the details, of an attic may be found in Chambers, 'Civil Architecture,' edition by Gwilt, 1825; or in Quatremère de Quincy, 'Encyclopédie Méthodique,' 1788; Millin, in his 'Dictionnaire des Beaux Arts,' has some long notes upon the subject, mainly copied from those of the 'Encyclopédie Méthodique.'

ATTIC DIALECT, is a term which applied to designate one of the varieties of the ancient Greek language. A close connection and relationship existed between the old inhabitants of Attica and the Ionians; and in conformity with this fact, we find it stated (Strabo, p. 333) that the Ionic form of the Greek language, or the Ionic dialect, as it is generally called, "was the same as the old Attic, for the ancient Athenians were called Ionians." But in course of time the language of Athens, which was improved by a great number of writers, gradually acquired a distinct character, and also a decided pre-eminence, owing to the excellent works which were written in it on almost every branch of literature. Most of the great works of antiquity which have been transmitted to our times are written in the Attic dialect. Some writers have made two, and some three divisions of the Attic dialect, with reference to extant writers; but the general division of the Attic dialect into *old* and *new* seems to be sufficiently exact. To the former division belong Æschylus, Sophocles, Euripides, Aristophanes, Antiphon, Thucydides, &c.; to the latter, Demosthenes, Æschines, and the contemporary orators. The language of Xenophon, Plato, and indeed Aristophanes also, may be considered as possessing a character somewhat intermediate between the two classes, and the name of *middle* may consequently be given to it; but it would be difficult to say exactly how a writer of this middle class is to be distinguished from the writers of the *new* Attic.

After the time of Alexander, when the Greeks were more united as a nation, the superiority of Athenian literature made the language of Athens the common language of those who wrote pure Greek. Aristotle may be considered as the earliest extant writer, not an Athenian by birth, who adopted the language of Athens. The Attic dialect, then somewhat modified under Macedonian influence and by local circumstances, became the common written language of the educated Greeks. We find accordingly, under the successors of Alexander, and afterwards under the Romans, a series of Greek prose writers belonging to various countries, but all attempting to write one common language. These writers no doubt have each some peculiarities; but these peculiarities are not of that kind which distinguish the Ionic Greek of Herodotus, or the Doric Idylls of Theocritus from the language of Thucydides and Euripides. This common language of the learned Greeks was called the common dialect (*ἡ κοινή*, or *ἡ Ἑλληνικὴ διάλεκτος*): Polybius, a native of the Peloponnesus, Strabo of Asia Minor, Diodorus of Sicily, and others, belong to the writers who use the Common Dialect. Some late writers affected rather to imitate the pure old Attic standard than to use the modified Attic, or Common Dialect, as Lucian, Arrian in his Anabasis, Aristides, &c. The name of Atticists (*Ἀττικισταί*) was given to this artificial class of writers, but especially to such imitators as Aristides. [ARISTIDES, ÆLIUS, in BIOG. DIV.] The real characteristics of the Attic dialect can only be known by a careful study of the writers. The reader may consult Maittaire's 'Græcæ Linguæ Dialecti, by Sturz, 1807; Buttmann's 'Greek Grammar;' and Matthiæ's 'Greek Grammar.'

ATTORNEY is a person substituted (*atourné, attornatus,*) from *atourner, attornare,* to substitute, and signifies one put in the place or *turn* of another to manage his concerns. He is either a private attorney authorised to make contracts, and do other acts for his principal by an instrument called a letter of attorney; or he is an attorney at law, practising in the several courts of common law. The latter description only will be treated of under this head. As to the former, see LETTER OF ATTORNEY.

An attorney at law answers to the *procurator*, or proctor, of the civil and canon law, and of our ecclesiastical courts. Before the statute 13 Edward I., c. 10, suitors could not appear in court by attorney without the king's special warrant, but were compelled to appear in person, as is still the practice in criminal cases. The authority given by that statute to prosecute or defend by attorney formed the attorneys into a regular body, and so greatly increased their number, that several statutes and rules of court for their regulation and for limiting their number were passed in the reigns of Henry IV., Henry VI., and Elizabeth: one of which, the 33 Henry VI. c. 7, states, that not long before there were only six or eight attorneys in Norfolk and Suffolk, '*quo tempore magna tranquillitas regnabat;*' but that their increase to twenty-four was to the vexation and prejudice of the counties; and it therefore enacts, that for the future there shall be only six in Norfolk, six in Suffolk, and two in Norwich—a provision which has been since signally evaded, though not repealed. It will be convenient to consider—

1st. The admission of attorneys to practise, their enrolment, and certificates.

2d. Their duties, functions, privileges, and disabilities.

3d. The consequences of their misbehaviour.

4th. Their remedy for recovering their fees, &c.

1st. *The admission of attorneys to practise, their enrolment, and certificates.*—The earlier regulations as to the admission of an attorney (see 3 Jac. I. c. 7, s. 2, and rules of courts in 8 Car. I., and 1654) required that he should serve for five years as clerk to some judge, serjeant, counsel, attorney, or officer of court; that he should be found, on examination by appointed practisers, of good ability and honesty; and that he should be admitted of, and reside in, some inn of court or chancery, and keep commons there. These were superseded by the 2 Geo. II. c. 23, and subsequent statutes; but all of them (except the Stamp Acts) were repealed by and consolidated in the 6 & 7 Vict. c. 73, by which the control of the profession, from the period of admission, and so long as the attorney continues in practice, is confided to the Incorporated Law Society, which is appointed registrar of attorneys and solicitors. The Commissioners of Stamps are not to grant any certificate until the registrar has certified that the person applying is entitled thereto; and the commissioners are annually to deliver to the registrar all such certificates, with the date when they were granted. Persons who previously to this Act had discontinued their certificates to practise in the superior courts, but who were in the habit of practising in the inferior courts, and at the sessions and assizes, are now obliged to take out certificates, and are thus brought under the controlling power of the Incorporated Society. No person can practise as an attorney in the superior courts unless he has been bound by contract in writing to serve for five years as clerk to a regular attorney, and has continued five years in such service, and has been afterwards examined, sworn, admitted, and enrolled in the manner provided by the Act, under a penalty of 50*l.* and an incapacity to sue for his fees. This provision is extended to practising in the county court or the quarter sessions; and by 34 Geo. III. c. 14, s. 4, any person practising as an attorney, without due admission and enrolment forfeits 100*l.*, and is disabled from suing for his fees. By the 6 & 7 Vict. persons having taken the degree of bachelor of arts, or bachelor of law, in the university of Oxford, Cambridge, Dublin, Durham, or London, and having served under contract in writing for *three* years with an attorney, and having been actually employed during the three years by such attorney or his agent in the business of an attorney, shall be qualified to be admitted as fully as if they had served five years; provided the degree of bachelor of arts was taken within six years after matriculation, and the degree of bachelor of law was taken within eight years after matriculation: the binding to the attorney must also be within four years after the taking of the degree. An affidavit must be made within six months from the date of the articles of the execution thereof by the attorney and by the clerk, which affidavit must be filed in the court where the attorney is enrolled, and be read in open court before the clerk is admitted and enrolled an attorney. By the last Stamp Act a duty of 80*l.* is imposed upon the articles of clerkship of attorney, and 5*s.* on the counterpart. No attorney is allowed to have more than two articled clerks at once, and these only during such time as he is actually in practice on his own account, and not at any time during which he himself is employed as clerk by another attorney. The clerk, in order to be admitted an attorney, must actually serve five years under his articles; but in case the attorney dies, or discontinues to practise, or the articles are by mutual consent cancelled, then the clerk may serve the residue of the time under articles to any other practising attorney, and the new articles are not subject to stamp, 34 Geo. III. c. 14, s. 5, except the duty of 1*l.* 15*s.* The articled clerk may serve one year, but not a longer time, with the agent of the attorney to whom he is articled: a plan generally adopted by country clerks, who thus acquire a year's experience of the practice in London, without delaying their admission: and an articled clerk who becomes *bonâ fide* a pupil to a barrister, or certificated special pleader, *for one whole year*, may be admitted in the same manner as is done if he serves one year with the agent of the attorney to whom he is bound. Before the clerk can be admitted an attorney, he must be examined according to the Rules of Court of Hilary Term, 1853, at the Hall of the Incorporated Law Society, before one of the Masters of the Courts of Common Law, and four out of sixteen attorneys annually appointed by the Common Law judges. In conducting this examination, 75 questions are prepared and printed, arranged under the following heads:—1, Common and statute law, and practice of the courts; 2, conveyancing; 3, equity and practice of the courts; 4, bankruptcy and practice of the courts; 5, criminal law and proceedings before justices of the peace. There are some preliminary questions, two of which are for the purpose of ascertaining what law-books have been read and studied, and if the person under examination has attended lectures upon the law. Being found duly qualified, the clerk must also cause an affidavit of the actual service under the articles, sworn by himself or the attorney with whom he has served, to be filed in the court to which he seeks admission; and he must make oath (or affirmation, if a Quaker) that he has duly paid the stamp duty on the articles, and that he will truly and honestly demean himself as an attorney; he must also take the oath of allegiance, or, if a Roman Catholic, the declaration and oath prescribed by the Roman Catholic Relief Act. The attorney pays a stamp duty on his admission of 25*l.* His name is then enrolled without fee by the officer of court, in books appointed for the purpose: to which books all persons have free access, without payment of any fee. When the attorney is admitted, he subscribes a roll, which is the original roll of attorneys, of which the court takes notice as the recorded list of its officers, and from which the names are copied into the books. An attorney duly sworn, admitted, and enrolled in any of the superior courts of *law*, may be sworn and admitted in the courts of *equity* without fee or stamp duty; and so a solicitor in any court of equity at Westminster may be sworn, admitted, and enrolled an attorney of her Majesty's courts of law; and an attorney in a superior court at Westminster is capable of being admitted in any inferior court of record. An attorney admitted in one court of record at Westminster, may, by the consent in writing of any other attorney of another court, practise in the name of such other attorney in such other court, though not himself admitted in such court. But if any sworn attorney knowingly permit any other person, not being a sworn attorney of another court, to practise in his name, he is disabled from acting as an attorney, and his admittance becomes void.

In addition to the examination, swearing, admission, and enrolment, an attorney, in order to be duly qualified for practice, must take out a certificate at the Stamp-office every year between the 15th November and 16th December for the year following, the duty on which is 9*l.* if he reside in London or Westminster, or within the delivery of the two-penny post, or within the city of Edinburgh, and has been in practice three years; or 4*l.* 10*s.* if he has been admitted a less time; and if he reside elsewhere, and has been admitted three years, 6*l.*; or if he has not been admitted so long, 3*l.*; and if he practise without certificate, or without payment of the proper duty, he is liable to a penalty of 50*l.* and an incapacity to sue for his fees. (55 Geo. III. c. 184, s. 27.) But by the 44 Geo. III. c. 98, s. 10, these penalties can only be sued for by the Attorney-General, like other stamp penalties. The omission by an attorney to take out his certificate for one whole year incapacitates him from practising, and renders it necessary to obtain leave of the court to renew his certificate on payment of the arrears of certificate duty, and such penalty as the court thinks fit.

2. *The duties, functions, privileges, and disabilities of attorneys.*—The principal *duties* of an attorney are care, skill, and integrity; and if he be not deficient in these essential requisites, he is not responsible for mere error or mistake in the exercise of his profession. But if he be deficient in proper skill or care, and a loss thereby arises to his client, he is liable to a special action on the case: as, if the attorney neglect on the trial to procure the attendance of a material witness; or if he neglect attending an arbitrator to whom his client's cause is referred; or if he omit to charge a defendant in custody at the suit of his client, in execution within the proper time. When an attorney has once undertaken a cause, he cannot withdraw from it at his pleasure, since this would injure his client; and though he is not bound to proceed if his client neglect to supply him with money to meet the necessary disbursements, yet before an attorney can abandon the cause on the ground of want of funds, he must give a sufficient and reasonable notice to the client of his intention. When deeds or writings come to an attorney's hands in the way of his business as an attorney, the court, on motion, will make a rule upon him to deliver them back to the party on payment of what is due to him on account of professional services and disbursements, and particularly when he has given an undertaking to re-deliver them: but, unless they come to his hands strictly in his business as an attorney, the court will not make a rule, but leave the party to bring his action against the attorney.

An attorney duly enrolled and certificated is considered to be always personally present at court, and on that account has still some *privileges*, though they are now much narrowed. Till lately he was entitled to sue by a peculiar process, called an attachment of privilege, and to be sued in his own court by bill; but the Act for uniformity of process, 2 Will. IV. c. 39, abolished these distinctions, and an attorney now sues and is sued like other persons. By reason of the supposed necessity for his presence in court, an attorney is exempt from offices requiring personal service, as those of *sheriff, constable, overseer of the poor*, and also from serving as a juror. These privileges being allowed not so much for the benefit of attorneys as of their clients, are confined to attorneys who practise, or at least have practised within a year.

An attorney is also subject to some disabilities and restrictions. By rule of Michaelmas Term, 1854, no attorney can be bail for a defendant in any action. By 5 Geo. II. c. 18, s. 2, no attorney can be a justice of the peace for a county while in practice as an attorney; and no practising attorney can be a commissioner of the land tax without possessing 100*l*. per annum. No attorney who is a prisoner in any prison, or within the rules or liberties thereof, can sue out any process, or commence or prosecute or defend any action or suit; and if he so commence, prosecute, or defend any action or suit, he will be punishable as for a contempt of court and be incapable of recovering his fees.

3. *The consequences of an attorney's misbehaviour.*—The court which has admitted an attorney to practise treats him as one of its officers, and exercises a summary jurisdiction over him, either for the benefit of his clients, or for his own punishment in case of misconduct. If he is charged on affidavit with fraud or malpractice, contrary to justice and common honesty, the court will call upon him to answer the matters of the affidavit; and if he do not distinctly deny the charges imputed to him, or if he swear to an incredible story in disproof of them, the court will grant an attachment. If the misconduct of the attorney amount to an indictable offence, the courts will in general leave him to be indicted by the party complaining, and will not call upon him to answer the matters of an affidavit. If the attorney has been fraudulently admitted, or has been convicted of felony or any other offence which renders him unfit to practise, or if he has knowingly suffered his name to be used by a person unqualified to practise, or if he has himself acted as agent for such a person, or if he has signed a fictitious name to a demurrer purporting to be the signature of a barrister, or otherwise grossly misbehaved himself, the court will order him to be struck off the roll of attorneys. But striking off the roll is not a perpetual disability; for in some instances the court will permit him to be restored, considering the punishment in the light of a suspension only.

4. *The attorney's remedy for recovering his fees.*—An attorney may recover his fees from his client in an action of debt or *indebitatus assumpsit*, which he may maintain for business done in other courts as well as in that of which he is admitted an attorney. But an attorney cannot recover for conducting a suit in which, owing to gross negligence or other cause, the client has had no benefit whatever from the attorney's superintendence. By the 6 & 7 Vict. c. 73, s. 37, no attorney shall sue for the recovery of his fees or disbursements till the expiration of one calendar month after he has delivered, or sent by post, to his client a bill of such fees or disbursements, and subscribed with his own hand, or accompanied by a letter so subscribed; and on application of the party chargeable by such bill, the court, or a judge of the court in which the business is done, may refer the bill to be taxed by the proper officer; and if the attorney, or the party chargeable, shall refuse to attend such taxation, the officer may tax the bill *ex parte*, pending which reference and taxation no action shall be commenced for the demand; and on the taxation and settlement of the bill, the party shall pay to the attorney, or as the court shall direct, the whole sum due on the bill, or be liable to attachment or process of contempt; and if it is found that the attorney has been overpaid, then he shall forthwith refund. The statute applies not only to fees and disbursements for business done in a court of law or equity, but to conveyancing or other business not transacted in any court of law or equity.

The solicitor is by the statute also enabled to obtain the taxation of his own bill without the expense and delay of an action. The certificate of the taxing-master is final; and it is provided that a bill shall not be taxed after a verdict or writ of inquiry, or after twelve months from the delivery of the bill, except under special circumstances, and under no circumstances after twelve months' payment.

To assist an attorney in recovering his costs, he has a *lien* for the amount of his bill upon the deeds and papers of his client which have come to his hands in the course of his professional employment; and till his bill be paid, the court will not order them to be delivered up, nor can an action be maintained for them. The attorney has also the same *lien* on any money recovered by his client which comes to his hands in the character of his attorney. As a further security to the attorney, his client is not permitted to discharge him and substitute another without obtaining the leave of the court or a judge's order for that purpose, which is never granted except upon the terms of paying the first attorney's bill. (See Bac. *Abridgment*, tit. *Attorney*, 7th ed.; Archbold's *Practice*, by *Chitty*.)

ATTORNEY, LETTER OR POWER OF. [Letter, or Power of Attorney.]

ATTORNEY-GENERAL. The attorney-general is a ministerial officer of the crown, specially appointed by letters-patent. He is, in principle, nothing more than the attorney for the sovereign, and occupies precisely the same relation that every other attorney does to his employer. The addition of the term 'general' to the name of the office probably took place in order to distinguish him from attorneys appointed to act for the crown in particular courts, such as the attorney for the Court of Wards, or the master of the Crown Office, whose official name is 'coroner and attorney for the queen' in the Court of Queen's Bench. By degrees the office, which has usually been filled by persons of the highest eminence in the profession of the law, has become one of great dignity and importance. The duties of the attorney-general are to exhibit informations and conduct prosecutions for such heinous misdemeanours as tend to disturb or endanger the state; to advise the heads of the various departments of government on legal questions; to conduct all suits and prosecutions relating to the collection of the public revenue of the crown; to file informations in the Exchequer, in order to obtain satisfaction for any personal wrong committed in the lands or other possessions of the crown; to institute and conduct suits for the protection of charitable endowments, in which the sovereign, as *parens patriæ*, is entitled to interfere; and generally to appear in all legal proceedings, and in all courts, where the interests of the crown are in question.

The precise rank and precedence of the attorney-general have frequently been the subject of discussion and dispute; the early history and origin of this office, upon which the question in a great measure depends, being matter of great obscurity. There is no doubt that at all times the king must have had an attorney to represent the crown in the several courts of justice; but in early times he was probably not an officer of such high rank as the attorney-general of the present day. There are no traces of such an officer till some centuries after the conquest; and it is clear that, until a comparatively late period, the king's serjeant was the chief executive officer for pleas of the crown. (Spelman, 'Gloss.' tit. 'Serviens ad legem.') In the old form of proclamation upon the arraignment of a criminal, the king's serjeant was, till very lately, always named before the attorney-general; and previously to the Commonwealth he invariably spoke before him in all criminal prosecutions, and performed the duty of 'opening the pleadings,' which since the Commonwealth has always been done by the junior counsel. In the reign of James I. a curious altercation between Sir Francis Bacon, who was then attorney-general, and a serjeant-at-law, upon this subject, is related in Bulstrode's 'Reports,' vol. iii. p. 32, upon which occasion Lord Coke, who was then chief justice, said that "no serjeant ought to move before the king's attorney, when he moves for the king; but for other motions any serjeant-at-law is to move before him." He added, that when "he was the king's attorney, he never offered to move before a serjeant, unless it was for the king."

All questions respecting the precedency of the attorney-general and the serjeants were terminated in 1811 by a special warrant of his late majesty, George IV., when Prince Regent, by which it was arranged that the attorney-general and the solicitor-general should have place and audience at the head of the English bar.

A discussion arose in 1834, at the hearing of a Scotch appeal in the House of Lords, upon the question of precedency between the attorney-general and the lord advocate of Scotland, which was finally decided in favour of the former.

There is an attorney-general for each of the Duchies of Lancaster and Cornwall, and for the County Palatine of Durham.

ATTORNMENT is defined by Lord Coke to be 'an agreement of the tenant to a grant of a seigniory, rent, or manor, or of the donee or lessee to a grant of the reversion or remainder.' For originally, as the tenant could not alien without consent of the lord, so the lord could not alien without consent of the tenant. An attornment, as this consent was called, was, therefore, necessary in all conveyances of a manor, services, remainder or reversion which operated by the common law: for in such case, if there was no attornment, the grant was void. But by the statute 27 Hen. VIII. c. 10, an attornment was not necessary where the estate passed by way of use: and now, by the statute 4 & 5 Anne, c. 16, ss. 9, 10, and 11 Geo. II. c. 19, s. 11, both the necessity and efficacy of attornments, as regards the lord's estate, have been almost entirely taken away. It is a forfeiture for a tenant for years to attorn or pay rent to a stranger. (Comyn, *Digest*; Co. Litt. 309, a; Blackst. *Comm.*, Mr. Kerr's ed. vol. ii. 71, 269.)

ATTRACTION (from two Latin words *ad* and *traho*, signifying *to draw towards*), a term the meaning of which has been obscured by the verbal disputes of a century and a half. It denotes, generally, the power or principle by which all bodies mutually tend towards each other, without regard to the cause or kind of action, which may be the means of producing this effect. We shall here confine ourselves to the *general* action of attraction, and for *particular* cases, refer to articles Electrical Attraction, Capillarity, Osmose, &c.

Anaxagoras, B.C. 500, is said to have been the first who applied the idea of attraction to the heavenly bodies, supposing that they all revolve round the earth; and in this he was followed by the chief atomists [Atoms]. The first of the moderns, who had correct ideas on this subject was Copernicus, the restorer of the Pythagorean system of the universe, who considered *gravity* as "a certain natural *appetence* impressed on matter." Kepler, too, calls gravity "a corporeal and mutual *affection* between bodies," adding that the tides are caused by a *virtus tractoria quæ in luna est*. The first person in this country who revived the doctrine of attraction was Dr. Gilbert of Colchester, and the next was Lord Bacon. It was Dr. Hooke, however, who, before Newton's time, perfected most the theory of this subject, showing not only the facts, but in a general way the law also, of attraction (which he called a *conatus accedendi*). The true law however, that of the inverse square of the distance, was discovered by Newton, who about the year 1666, being driven from London by the plague, was led by circumstances to discover it by mathematical investigation.

Attraction may be divided into two kinds (1), that which acts only at insensible or *infinitesimal* distances; this kind of attraction existing between atoms manifests itself in several ways, (i.) as Chemical Affinity [CHEMICAL AFFINITY]; (ii.) as CRYSTALLIZATION, which may be considered as a *polarity* in molecular aggregation, (iii.) as ADHESION and COHESION, under which may be included the phenomena of CAPILLARITY; and (2) that which acts at *all* distances however great; this is manifested chiefly in the phenomena of GRAVITATION, but also in ELECTRICAL, MAGNETIC, and other attractions. In the present article we shall speak chiefly of *Adhesion* and *Cohesion*, referring to other articles for the rest.

All attractive forces, whether exerted between atoms or masses, obey the general law mentioned above, namely,—the attractive force is inversely as the *squares* of the distances between the attracting bodies. This is exemplified by the following table:—

Distance.	1	2	3	4	5	6	7	8	9	10	&c.
Intensity of attraction.	1	$\frac{1}{4}$	$\frac{1}{9}$	$\frac{1}{16}$	$\frac{1}{25}$	$\frac{1}{36}$	$\frac{1}{49}$	$\frac{1}{64}$	$\frac{1}{81}$	$\frac{1}{100}$	&c.

When two smooth surfaces of the *same* substance are pressed together, they *cohere*. This *cohesion* is very evident, if we take plates of lead, or of glass, which will remain so firmly united, that in many cases they may be worked as one single piece. *Adhesion*, on the contrary, is said to take place between two surfaces of *different* substances, such as a solid and a liquid. Thus, when a liquid *wets* a cup, &c., it is said to *adhere*, and *not* to *cohere* to the cup. The force of this adhesion may be measured approximately by the method of Guyton and Quetelet, who, with Gay-Lussac, have studied this subject. They formed discs of various substances, and placed them as counterpoises to one scale-pan of a balance. They then allowed the disc to fall gently on the surface of some liquid, to which it adhered with some force, this force being then measured by placing weights in the opposite scale-pan until the force of adhesion was just neutralised, and the disc flew up from the liquid. By this process they obtained the following results:—

Metal Discs, 1 in. in diameter.	Force of adhesion to Mercury in grs.	A Glass Disc, 4·6 in. in diameter adhering to	Force of adhesion in grains.
Gold	446	Water	414·7
Silver	429		
Tin	418	Alcohol of	
Lead	317	(i) Sp. gr. = ·8196	477·4
Bismuth	372	(ii) Sp. gr. = ·8595	505·1
Zinc	204	(iii) Sp. gr. = ·9415	569·8
Copper	140		
Antimony	126	Turpentine Sp. gr. = ·8695	523·6
Iron	115		
Cobalt	8		

The force of *Cohesion*, on the other hand, has been approximately measured by observing the size and weight of the *drop* which any liquid forms when suspended on the end of a rod.

When two bodies, both of them capable of motion, attract one another, it is easily demonstrable by mathematical reasoning, that they will mutually move towards one another, and will meet in their centre of gravity; this point being, of course, nearer to the larger body, if they are homogeneous. Hence the smaller body will have a greater velocity communicated to it by the attractive force, and we shall find that the law of attraction may be expressed as depending not only on the distance, but also that it varies *directly* as the product of the masses of the bodies; so that, if M and m be the masses, and r the distance between them, the force of attraction will be $= \frac{\text{M}m}{r^2}$.

In order rigidly to test these laws, various experiments have from time to time been instituted. Thus, it is plain that any large body brought near to a smaller one, must cause, according to this law, a motion in the smaller body much greater than that in the larger one. This is well seen in the celebrated experiment of Cavendish, described in the 'Phil. Trans' for 1798. It was this: If we balance one ball of lead by another on a horizontal lever, no horizontal oscillation takes place; but any little disturbance makes the lever turn completely round again and again, till friction restores the equilibrium. Cavendish balanced two balls of lead very nicely on a lever, which he suspended by a thread. A firm stand was provided, and the whole was inclosed in a wooden case, to prevent agitation by the air, inserting only a telescope and a lamp on one side. When the apparatus was firm and no motion was perceived in the interior pendulum, other leaden balls of considerable size were suddenly presented, outside the case, to each end of the lever, whereupon horizontal oscillations immediately began in the lever like those of a pendulum upon the earth—such oscillations as would take place if the balls attracted one another. He observed the duration of these oscillations; and thence, knowing the duration of the oscillation which the earth creates in a pendulum, and also knowing the relative densities of lead and water, he ascertained that if the commonly received law of attraction be correct, the earth's average density must be $5\frac{1}{2}$ times as great as that of water. Hutton, on recalculating his result, found reason to think the $\frac{1}{2}$ should be $\frac{1}{10}$.

It is evident that if matter attract matter, a mountain contiguous to a plumb-line or a spirit-level will, in a slight degree, alter the position of the former, or the surface of the latter. We can hardly expect to measure the trifling displacement by direct means; but since the instruments alluded to are the *regulators* of some astronomical instruments, it is plain that a false plumb-line or level may show itself by giving false positions to the stars. And it is well known that the mean of a number of observations detects very small instrumental errors. Bouguer, in Peru, suspected that the proximity of Chimboraço affected his plumb-line; and even detected an error of a few seconds which he could in no other way explain: but his results remain unverified. In 1772, Maskelyne (one of the best observers of his time) proceeded to Scotland, to try the effect of Schehallien. He made a great number of observations both north and south of the mountain; for he argued that since the plumb-line, if disturbed, must tend towards the mountain in both cases, the discordance he sought would be doubled, and more easily perceptible. He found in this way, that the north plumb-line and the south plumb-line made an angle of $11\frac{1}{2}''$ more than could be explained by the difference of latitude of his two stations. Hutton, on calculating the mean density of the earth from this result, found it five times as great as water: a result very nearly that afterwards produced by Cavendish, when it is considered that both the mean density and form of such a mass as Schehallien could not be very accurately determined.

In 1810, Baron Zach undertook a similar labour, in which he employed a different instrument, and a different method of verification. He was carrying on a trigonometrical survey in the neighbourhood of Marseille, and he had three small observatories near Mount Mimet, north of that town. He measured on the earth their position with respect to other stations too distant from the mountain to be sensibly affected, and he then obtained the latitude of his observatories by astronomical observation on the spot. All three, without exception, gave a difference of $2''$ between the geodesical and astronomical latitudes, and in all the observed latitude was greater than the measured, being the sort of effect which would be produced by attraction in the mountain. M. Zach published the fullest detail of his method, and all the observations, in his 'Attraction des Montagnes,' Avignon, 1814. For details of Maskelyne's measurements, see Hutton's 'Tracts,' vol. ii., and 'Phil. Trans.' 1778.

According to the common notion entertained of matter, it is solid, or at least composed of particles which come into absolute contact. If we could substantiate the first supposition, it would still be apparent that the term *force of solidification* must take the place of *force of cohesion*, and give rise to inquiries into its quantity and mode of action: and even if we could imagine absolute contact of particles, we should find it necessary to append a notion of some force by which particles in contact remain in contact when some of them are put in motion, so as to draw the rest after them. But the balance of probabilities is very strong indeed against the supposition that matter is composed of particles in contact; so much so, that we are almost entitled to conclude it to be composed of particles separated by interstices of much greater dimensions than the particles themselves. If any one should assert the particles of the densest matter to be as far apart in proportion to their bulk as the bodies of the solar system, it would be impossible to bring any direct evidence in contradiction.

Such being the case, we may ask—1. What is the force of cohesion? for such a force there certainly is. 2. What is that law of action by which the particles of bodies are not drawn into absolute contact, but compelled to remain separate, and yet prevented from separating indefinitely?

With regard to the first question, it is most probable that as two bodies approach each other, a strong repulsive force is the cause of the first phenomenon which is perceived. When one billiard ball strikes another, we have no evidence, except that of our senses, of absolute contact taking place; that is to say, we only know that the first visible action takes place when the distance of particles is too small for the eye to perceive. All the evidence which is at all conclusive, is against the supposition of such contact being produced: and we are obliged to admit that our explanation must end in the statement that, arise from whence it may, there is a power in matter by which other matter is repelled, and which begins to act before contact has taken place. But if two pieces of solid matter be pressed together with great force, it would seem as if the particles would thereby be brought within a degree of nearness at which an attractive force begins to act. Two bits of lead pressed together remain in coherence even in a vacuum; and metal plates can be hammered together until the cohesion is as strong as if they had been naturally united.

The cohesive force is an absolute phenomenon, but if we suppose the particles of matter not in contact, it then becomes necessary to admit a new repulsive force, of which the sphere of action is interior to that of the cohesive force. Complete interstices can only exist upon the supposition that, at a certain distance, the cohesive force is destroyed, or at least overcome, by a counterbalancing repulsion. From the known effects of heat, it is supposed that *caloric*, a name which indicates the cause of heat, plays a prominent part in the production of the repulsion. Nothing positive, however, has yet been established on this subject: we can only make use of phenomena as they exist, to overturn the common impressions, by means of which *force*, the great agent of the universe, meaning the cause of visible display of motion excited or motion prevented, is postponed to notions of *matter*, or *impenetrability*, or similar words, which, if made accurate by close attention, and freed from such latent assumptions as arise from the unassisted senses, will be found to amount to the same idea.

The arguments against absolute contact are almost insuperable: if we yield to them, we are immediately obliged to admit that particles really act on each other at a distance. Nor will any suppositions as to caloric afford us the means of avoiding such a conclusion. If caloric be matter, we must first explain *its* cohesion or repulsion before we can apply it to explain that of other matter: if caloric be not matter, we gain nothing in the way of avoiding difficulty; for an agent which is not matter, but something else, with new properties superadded to the common and visible properties of matter, is as difficult as ordinary matter with the express addition of power over other matter at a distance. And it must be observed, that if we are rationally compelled to allow such power to a particle upon a particle, there is no new difficulty in the attraction of *gravitation*. If A can act upon B at the millionth part of an inch, there is no *à priori* difficulty in the notion that two A's together can act on B at twice the distance with as much visible effect as a million of A's collected can act at a million of times the distance, and so on. It must not, however, be supposed that we mean to infer that gravitation and cohesion are both referable to the Newtonian law of attraction, although this has been since reduced to more than a possibility. This remarkable addition to the nascent theory of molecular forces is the work of O. F. Mossotti, and was published in a pamphlet entitled 'Sur les Forces qui régissent la constitution intérieure des corps, aperçu pour servir à la détermination de la cause et des lois de l'action moléculaire,' Turin, 1836, 4to. This paper is translated in Taylor's 'Scientific Memoirs,' vol. i.; and Mr. Pratt, in the second edition of his 'Mechanical Philosophy,' observing that Mossotti's analysis, though conducted with an ultimate view to complex application, is really, for the present, only applied to simple cases, has given the mathematical view necessary to include those simple cases and no more, in a perfectly sufficient manner.

The observed facts are, that particles which are very nearly in contact with one another repel each other in a manner which certainly depends, among other things, on the temperature; but that at a certain distance they cease to repel, and begin to attract each other, and that with considerable force; at a still greater distance that attraction becomes comparatively feeble, and coincides with what is called the attraction of gravitation, varying inversely as the square of the distance. That this attraction of gravitation, and no other, exists at ordinary sensible distances, is fully proved by the Cavendish experiment.

Many hypothetical laws might be constructed which fulfil all these conditions; but the great interest of Mossotti's investigation, and perhaps much of its value, consists in his having taken a theory actually existing, imagined upon grounds with which his views had no necessary connection, and upon his having given a basis of the utmost simplicity to the numerical law on which he proceeded. This basis is no other than that all molecular attractions and repulsions vary inversely as the squares of the distances.

When Æpinus explained Franklin's electrical theory, his hypothesis was that the particles of matter repel one another, and also the particles of the electrical ether, which he supposed to exist and to be attached to particles of ordinary matter. But he supposed the particles of ether to attract the particles of matter; so that of the two species of particles, called matter and ether, each repels the particles of its own kind and attracts those of the other. Æpinus even went so far as to suppose that the attraction of gravitation might be a necessary consequence of such a theory, on the supposition that the attraction of the matter and ether was a little greater than the repulsions. So far Mossotti has adopted his views; but, by applying mathematical analysis, he has shown what Æpinus could not have had the least reason to suppose, namely, that attraction of cohesion, the repulsion which takes place when the distance is smaller than that of cohesion, and the attraction of gravitation, which exists at distances too great for cohesion, are all to be found among the consequences of this theory.

If there exist in space molecules of matter which repel each other, in a fluid or ether of which the particles also repel each other, while the particles of the matter attract those of the ether, it is obvious that each of the particles of matter will, by its attraction, collect about it a condensed atmosphere of ether. If the attractions and repulsions be all inversely as the squares of the distances, Mossotti finds that, in consequence of the atmospheres of ether, two molecules at a distance r (the attraction of the particles of matter for those of ether being presumed a little, and but a little, greater than the repulsion of the particles of matter from each other) will repel each other with a force represented with great approximation by the formula

$$\frac{A(1+\alpha r)\epsilon^{-\alpha r}-B}{r^2},$$

where A, α, B, are certain positive constants. To make the results agree with observed facts, α must be considerable, and A much greater than B. When the formula is positive, repulsion is represented; when negative, attraction. When r is very small, the formula is positive, and represents repulsion; when r increases to a certain value, it vanishes, and afterwards becomes negative: at the value of r just mentioned there is stable equilibrium. As r still increases the attraction increases, becomes a maximum at another certain value of r, and afterwards, if α be considerable, diminishes as the inverse square of the distance, or in a ratio incomparably near to it. All this agrees with the facts of observation, and with the numerical law of the facts as far as we know it; to which it must be added that an increase of the density of the ether would increase the distance at which particles are in equilibrium, which is generally done by increase of temperature.

We may also make it apparent to the mathematician that laws of attraction may very easily be expressed which shall combine the leading circumstances connected both with gravitation and cohesion in one formula. Let us suppose, for instance, that at the distance r, the accelerating force of two equal particles on each other is expressed by

$$\frac{a}{r^m}\left(1-\frac{b}{r}\right)\left(\frac{c}{r}-1\right)+\epsilon^{-\frac{m}{r}}\,\frac{n}{r^2}$$

positive values denoting attraction, and negative values repulsion. If a and m be made sufficiently small, the first term may be made insensible at all finite distances, and the second as near as we please to the Newtonian law. But when r is very small, the second term becomes insensible, and such a value may be given to n that the first term shall be of sensible value, as follows: Let c be greater than b, both being quantities of that order of smallness at which the Newtonian term becomes insensible. Then when r is little greater than c, the first term is negative; when r lies between c and b, it is positive; and when r is less than c, it is negative again.

The solid, fluid, and gaseous states of matter show the rise and progress of a repulsive force generally produced by the action of heat. In the first, the particles absolutely attract, in the third they absolutely repel, each other; but in the second the repulsive force almost counterbalances the attractive force, leaving only enough to create that weak degree of cohesion which exists in fluids, or at most that semi-cohesion which is observed in bird-lime, in gum-water, and the like. The transition from complete solidity to the gaseous state appears to be made through various degrees of fluidity, and the gradual hardening of melted sealing-wax is a familiar instance of a part of the gradation.

We now come to the question how the attraction of the particles of one heavenly body on those of another is established. For details of this very extensive subject, see GRAVITATION. The *resumé* of the argument is this: the phenomena which *do* take place in the heavens are those which common and undisputed mechanical and mathematical reasoning show *would* take place if the Newtonian law be true. This law is, that the force of attraction is *inversely* as the squares of the distances between the attracting bodies. Now, every phenomenon of importance has been gradually brought under the consequences of this law by various analysts. To recount instances would be to make a summary of astronomical terms; but we will select one, which, in one sense, is the most dubious, namely, the phenomena of the tides. For, whereas the place of the moon or a planet is predicted within from half a second to a second of time, the time of high water cannot yet be predicted within some minutes, at least in a port. How much this phenomenon may be affected by winds or the nature of the coast, is not difficult to conceive; but the following result is a striking specimen of accordance between theory and fact. If the tides proceed from Newtonian gravitation, the mean *tide-day*, or interval between successive times of high water, must be equal to the time between the moon's coming on the meridian above and below the horizon, or, roughly speaking, two tide-days make a lunar day. It is found by analysis, that if the Newtonian theory be true, the average tide-day must be exactly equal to half the average lunar-day, though particular instances of the two may differ many minutes. This is found to be the fact: for if the tide-day were more than half the lunar-day by as much as one-tenth of a second on the average, that is, if the tides lagged, one with another, by $\frac{1}{10}''$ daily, two thousand years would have seen high water at every possible part of the lunar-day. But for two thousand years it has never been denied that high water takes place at every port within a certain time (usually less than four hours) of the moon's coming on the meridian. Again, a permanent retardation would, in course of time, bring high water when the moon was precisely on the meridian, for a long succession of days together: a result which never has been observed, and which, according to the Newtonian theory, is impossible. [ACCELERATION OF TIDES.]

An immense number of accordances between theory and observation, and there being no assignable discrepancy whatsoever, of any considerable amount, form the nature of the proof of the Newtonian law. And it must be observed that this has not been done in a day, or by one person, but during more than a century and a half, and by philosophers of several countries—not by men prejudiced in favour of Newton, but the contrary; for it was long before his doctrines found their way over to the continent, and the dispute about the invention of fluxions had laid the foundations of a strong anti-Newtonian prejudice. We may observe, also, that England, where the veneration of Newton amounted almost to idolatry, has done much less towards the development of his system than either France, Germany or Italy; so that the Newtonian system was really fully established by those who had every national and personal bias to endeavour to overturn it. This it is necessary to state, because it is frequently asserted that the prevailing system is sustained by the name and authority of Newton.

We shall now give some account of the disputes about the word attraction; but, first, we shall show how it was used by Newton. In his 'Optics,' he says, "*attraction* may be performed by impulse, or some other means. I use that word, to signify any force by which bodies tend towards one another." In his 'Principia,' he thus speaks of *gravity:* "Thus far I have explained the phenomena of the heavens and the sea by the force of gravity; but I have *not yet* assigned the cause of gravity . . . . The reason of these properties I have *not yet* deduced from phenomena, and I do not invent hypotheses. For whatever is not deduced from phenomena is called *hypothesis;* and hypotheses, be they metaphysical, physical, of occult qualities, or mechanical, have no place in experimental philosophy . . . . It is enough that gravity really exists, and acts according to laws laid down by us; and suffices to explain all the motions of the heavens and the sea."

The repeated use of the words *not yet* (*nondum*), would lead us to suppose that Newton thought that the cause of attraction might be discovered; and the sentence next following our preceding quotations shows that he leaned towards the notion of a highly subtle fluid, which was afterwards the *hypothesis* of those who constituted him their opponent: "Something might be added about that most subtle spirit which pervades and lies hid in all dense bodies; by force and action of which the particles of bodies mutually attract at the smallest distances, &c. . . . But this cannot be explained in few words; neither is there a sufficient number of experiments by which the laws of action of this spirit can be accurately determined and shown." ('Principia,' Schol. Gen. at the end).

Again, in the Optics, Newton dwells upon the same distinction between a phenomenon and its cause, and says that attraction may be caused by an impulse or some other unknown cause. But once for all, both against Newton and his opponents, we must observe, that an invisible fluid leaves the difficulties of the question where it found them. If this fluid have the common properties of matter, what is there to explain the mutual repulsion of its particles? Must they have a fluid to cause that phenomenon, and so on *ad infinitum,* or must an unknown cause of repulsion take the place of an unknown cause of attraction?

Leibnitz called attraction an *occult quality,* and *a miracle.* The first term was the horror of the continental philosophers about his time. Their predecessors had attributed various properties to matter which could not be proved by experiment, which were justly called *occult* (or hidden). In their desire to be rid of all such, succeeding philosophers would not only abolish the qualities of matter which they had invented, over which of course they had absolute power, but they tried also to abolish their own ignorance of the causes of the *sensible* qualities of matter. They would not have *occult* causes, and Leibnitz plainly confounds *occult* quality with *occult* cause. But it is needless to dwell upon the fact that the ultimate causes of all qualities are occult. When Newton adopted the word attraction, he did not take up and fix the meaning of a word which till his time had been ambiguous; still less, as some have asserted, did he retain a mystical meaning, which his followers afterwards cleared from absurdity. At and before the time of Newton, the word attraction was frequently used; for example, in the English translation of J. B. Porta, 1658, where to "attract" is used for to "draw forth," in opposition to "compound" or "lay together." But the philosophic use of the word is more conspicuous in Sir K. Digby's 'Treatise on Bodies,' 1669, where it is said that wherever "the first cause of the motion proceeds from that body towards which the motion is made," the effect is "properly called attraction," which is illustrated by the case of fire and air, in which, though there is an intermediate cause assigned by himself—namely, that the fire rarefies the contiguous air, which therefore ascends, and the surrounding air rushes in to supply its place—the author says that the fire *attracts* the air.

The objections made to the Newtonian attraction have been, with one or two exceptions, the work of those who had obviously not read Newton, or any geometrical work on the subject. We must take them in classes, and describe them as far as our limits will allow us to do.

1. We have those contained in axioms, which are either unproved or unmeaning, such as "*matter* cannot *act* where it *is* not." Those who bring this forward should explain the three hard words which they have put in italics; and we should then see whether this be self-evident or not. They should also remember that the celebrated immaterialism of Berkeley is, in several ways, an attack upon the word *matter* of exactly the same kind of argument as their own upon *attraction;* so that, in fact, they must assume a principle as to *matter* which they immediately proceed to oppose as to *attraction.* [BERKELEY, in BIOG. DIV.; IMMATERIALISM.] Again, in speaking of the place where matter *is,* they assume that the boundary of impenetrability is the same as the boundary of colour; a thing not only unproved, but from several circumstances unlikely.

2. We have those who would substitute pure hypothetical causes, such as Newton declines entering into, to explain the phenomenon of attraction. One writer requires no more than that all bodies should be composed of two distinct sets of particles, the one set of water, the other of some volatile fluid from which he thinks he deduces attraction; another is satisfied with an efflux and reflux of a fluid from and to the sun, to cause what he denominates the centripetal and centrifugal forces: evidently confounding the nature of the two in a manner which could not have been done by any person who had read Newton. A third fills the whole universe with streams of matter which are always passing through every point in every direction. On all these we shall only observe, that, in their attempts to produce an explanation of the phenomenon, they admit the phenomenon itself, which is all that Newton contended for.

3. We have those who leave out of view the main fact, that Newton explains phenomena as they really are, and who treat the *results* as hypothetical, as well as the *principle.* "Let the idea," says one writer, "of particles of matter attracting each other be impressed upon the mind, and it will then dilate upon their mutual actions, calculate the density of substances composed by them, whirl them at pleasure in empty space, and show in what manner their motions will be disturbed by the actions of each upon the other." But it is here forgotten that the "whirls" alluded to were not made "at pleasure," but they were "whirls" actually taking place, which were examined in order to see how they did whirl. Newton laid by his theory of attraction for years, as a forgotten thing, because he found that, with the received notions of the earth's magnitude, it would not give the moon the motion which she is actually found to possess: it was only when he received the more accurate measurement of Picard that he resumed his inquiry. Did he whirl his planets "at pleasure?"

4. Another class of objectors cannot conceive how attraction can be, and therefore they reject it. This argument is wholly unanswerable, because it is impossible to see on what part of the subject it bears, or how it is shown to be unreasonable to admit nothing as proved, except what can be conceived and accounted for. Nothing, except an absolute contradiction in terms, can be rejected on this ground.

5. All the above objections have been at one time or other advanced by men of knowledge: there remains one class more, namely, that of men, who, being ignorant of mechanics, deduce from wrong reasonings results which are not found in the heavens, on which they deny the truth of the principle. To this class, we are happy to say, personal aspersion, and imputations of intentionally misleading others, have been for the most part confined. The common mistake is a confusion between the words *velocity* and *force;* being much the same as if they confounded the drops which are pouring into a cistern for the time being, with the whole body of rain in the cistern itself. We quote another instance. A certain traveller remarks that it cannot be that the sun attracts a planet, at the very time when the planet is flying off from it. "What more could it do, if it were really repelled?" He does not see that the same argument applies to a stone thrown up into the air; and moreover, that what it could do more, if really repelled, would be to describe a *convex* curve, instead of one always *concave* towards the centre of force. To those who have any acquaintance with mechanics it is unnecessary to say anything upon such objections: to others who have not, we recommend, if they form an opinion upon this question, which it is noways necessary they should do, to follow either those who have studied it, or those who have not, whichever they have found most advantageous in the common business of life.

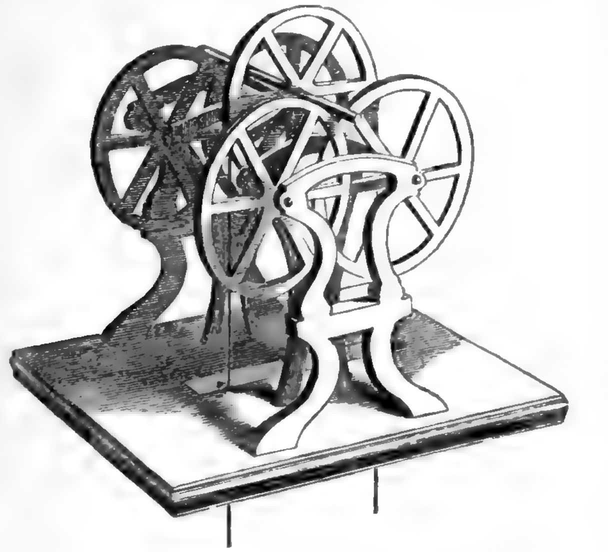
ATTRACTION, ELECTIVE. [CHEMICAL AFFINITY.]

ATTRACTION, ELECTRICAL. [ELECTRICITY.]

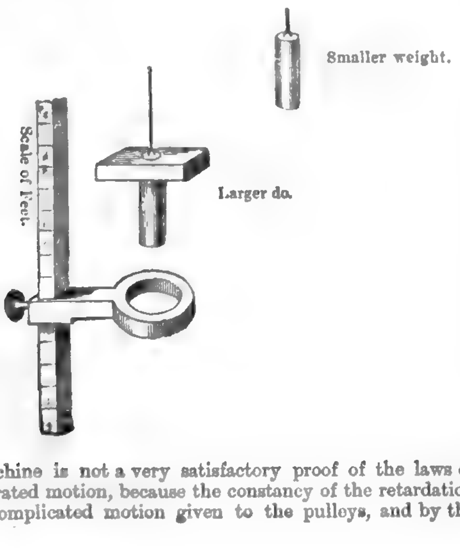
ATTWOOD'S MACHINE. When a constant or uniform force acts upon a mass, it produces equal accessions of velocity in equal times, and the whole distances described are as the squares of the times; that is, whatever length is described in the first second, four times as much is described in the first two seconds, nine times as much in the first three seconds, and so on; that is, the length described during the first second being called 1, that described during the second second is 3, that during the third 5, and so on. [ACCELERATING FORCE.] Where the weight of a mass is the pressure applied, and the *mass itself only* is moved,—that is, where a body falls freely *in vacuo,*—the velocity created in every second is found to be $32\frac{1}{6}$ feet, and the spaces described in successive seconds are $16\frac{1}{12}$ feet, three times $16\frac{1}{12}$ feet, five times $16\frac{1}{12}$, &c. These are distances too great on which to try experiments; and Attwood's machine is a method of contriving systems which shall move under constant forces of less amount, so that the space described during four or five seconds shall not require a very great fall. The principle made use of is one which is well known in mechanics, namely, that if a pressure A, acting uniformly upon a mass B, produce a certain velocity per second, it will only produce half that velocity when acting on a mass twice as great as B, &c., and will produce twice as much velocity in a mass half as great as B, &c. Suppose, for instance, weights of six and seven pounds hang over a pulley, the weight and friction of which are for the present neglected; if both weights were six pounds, the machine would not move: therefore, the moving pressure is the one pound by which the one weight exceeds the other. This weight, if it had only its own mass to move, or if it fell freely, would generate $32\frac{1}{6}$ feet of velocity per second; but before this system can move, $6+7$ or 13 pounds must be stirred by 1 pound, and there will only be the 13th part of $32\frac{1}{6}$ feet of velocity produced in one second—that is, about $2\frac{2}{5}$ feet. Therefore, in one second, the heavier weight will fall only $1\frac{1}{5}$ foot; and in 5 seconds, 25 times as much, or 30 feet. And the velocity acquired may be reduced in any proportion, by making the weights more nearly equal.

Attwood's machine is a pulley, the pivots of which, instead of being placed in a block, are sustained on FRICTION WHEELS (which see), to diminish the friction. Two weights are hung over this by a string, and the mass moved consists of the two weights, the pulley, and the friction wheels. But it is proved in mechanics that the effect, both of having the mass of the wheels to move, and of the friction, is a constant retarding force: for instance, in the preceding illustration, the machine might be so constructed that the effect should be to make the system move as if the larger weight were $6\frac{1}{4}$ pounds instead of 7, and the pulley were without density and friction. The velocity can be so far reduced as to render the resistance of the air insensible.

The length described in any time is measured by a vertical scale of feet, placed close to the line of motion of one of the weights. There is also a pendulum beating seconds in an audible manner. To measure the velocity acquired at any point, the moving pressure (the excess of

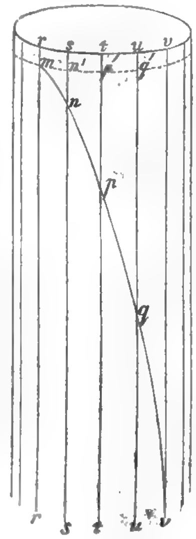


one weight above the other) must be taken off, in order that there may be no fresh accession of velocity, or that the system may proceed only with the velocity acquired. This is effected by making the larger weight in two parts, one part equal to the smaller weight, and the other of course to the excess or moving pressure. The latter is so formed that it cannot pass through a certain ring, while the former can. By fixing this ring to any required point of the scale of feet, the moving pressure is taken off when the larger weight passes through it.



Attwood's machine is not a very satisfactory proof of the laws of uniformly accelerated motion, because the constancy of the retardation caused by the complicated motion given to the pulleys, and by the friction, is a more difficult experimental fact than the one to be proved. Of the four principles,—1, the law of uniformly accelerated motion; 2, the constancy of the retardation caused by the having to communicate every acceleration also to the pulley and friction wheels; 3, the constancy of the retardation arising from friction; 4, the smallness of the resistance of the air to small velocities,—this machine may be made to prove any one to a spectator who admits the other three.

In Attwood's machine, a body falling freely is not observed, but one in which the descent is diminished in a known proportion. In an apparatus constructed by Morin, the actual descent of the falling body is exhibited and analysed in an ingenious manner. This apparatus consists of a cylinder moving on a vertical axis at a uniform rate by means of clockwork. Parallel with the axis of the cylinder are two wires, which serve as guides to a small cylindrical weight, which carries a pencil with its point pressing gently against the surface of the cylinder. There is a contrivance for detaching the weight, and also for letting it fall. Now it is evident that if the cylinder were at rest, the pencil in descending would simply trace a vertical line on its surface, while if the cylinder revolve and the pencil be at rest, it would trace a horizontal circle round it. If, however, while the cylinder is revolving on its axis at a uniform rate, the weight carrying the pencil be allowed to fall, the pencil will trace a curved line round the surface of the cylinder, and if the surface of the cylinder be divided into equal parts by the vertical parallel lines *r r*, *s s*, *t t*, &c., the intervals between the moments at which these parallels pass under the pencil will be equal, since the motion of the cylinder is uniform. Hence the vertical space through which the weight falls in the first interval will be *n' n*, in the first two intervals *p' p*, in the first three intervals *q' q*, and so on.



AUBAINE, the name of the prerogative by which the sovereigns of France formerly claimed the property of a stranger who died within their kingdom, not having been naturalised. It also extended to the property of a foreigner who had been naturalised, if he died without a will, and had not left an heir; as likewise to the succession to any remaining property of a person who had been invested with the privileges of a native subject, but who had quitted, and established himself in a foreign country. (See Merlin, 'Répertoire de Jurisprudence,' tom. i. p. 523.) It is called in the French laws, the 'Droit d'Aubaine.' Authors have varied in giving its etymology. Nicot ('Thresor de la Langue Françoyse tant ancienne que moderne,' fol., Paris, 1606) says it was anciently spelt Hobaine, from the verb *hober*, which signifies to remove from one place to another; Cujacius ('Opera,' fol., Neap. 1758, tom. ix. col. 1719) derives the word from *advena*, a foreigner or stranger; and Du Cange ('Glossar.,' v. Aubain) from *Albanus*, the name formerly given to the Scotch, who were great travellers. Ménage ('Dict. Etym.,' fol., Paris, 1694) says, some have derived the word from the Latin, *alibi natus*, a person born elsewhere, which seems the best explanation. (See also Walafridus Strabo, 'De Vitâ S. Galli,' l. ii c. 47.)

This practice of confiscating the effects of strangers upon their death was very ancient, and is mentioned, though obscurely, in one of the laws of Charlemagne, A.D. 813. ('Capitularia Regum Francorum, curante P. de Chiniac, fol., Paris, 1780, col. 507, § 6.)

The Droit d'Aubaine was originally a seignorial right in the provinces of France. Brussel, in his 'Nouvel Examen de l'Usage général des Fiefs en France pendant le xi., le xii., le xiii., et le xiv. siècle,' 4to, Paris, 1727, tom. ii. p. 944, has an express chapter, 'Des Aubains,' in which he shows that the barons of France, more particularly in the 12th century, exercised this right upon their lands. He especially instances Raoul, Comte de Vermandois, 1151.

Subsequently however it was annexed to the crown only, inasmuch as the king alone could give the exemption from it, by granting letters of naturalisation.

Various edicts, declarations, and letters patent relating to the Droit d'Aubaine, between the years 1301 and 1702, are referred to in the 'Dictionnaire Universel de Justice' of M. Chasles, 2 tom. fol., Paris, 1725; others, to the latest time, are given or referred to in the 'Code Diplomatique des Aubains,' par J. B. Gaschon, 8vo, Paris, 1818. The Duc de Levis, in his speech in the Chamber of Peers, when proposing its final abolition, 14th April, 1818, mentioned St. Louis as the first monarch of France who had relaxed the severity of the law (compare 'Etablissemens de S. Louis,' l. i. c. 3); and Louis le Hutin as having abolished it entirely in 1315 (compare the 'Recueil des Ordonnances du Louvre,' tom. i. p. 610), but, as it turned out, for his own reign only. Exemption from the operation of the Droit d'Aubaine was granted in 1364 by Charles V. in favour of persons born within the states of the Roman Church. Louis XI., in 1472, granted a similar exemption to strangers dwelling at Toulouse; and Francis I., in 1543, to strangers resident in Dauphiné. Charles IX., in 1569, allowed exemption from it to merchant-strangers frequenting the fairs at Lyon. Henry IV., in 1608, granted exemption to the subjects of the republic of Geneva. Louis XIV., in 1702, to the subjects of the Duke of Lorraine. (Chasles, 'Dict.,' tom. i. pp. 265, 267.) The Swiss and the Scotch of the king's guard had been exempted by King Henry II. (Bacquet, 'Traité de Droit d'Aubaine,' p. i. c. 7.)

Partial exemptions from the Droit d'Aubaine were frequently conventional, and formed clauses in treaties, which stipulated for reciprocal relief to the subjects of the contracting parties; these exemptions, it is probable, continued no longer than the peace which the treaty had procured, and some related to moveable goods only.

In the treaty of commerce between England and France, in 1606, the 'Jus Albinatûs,' as it is termed, was to be abandoned as related to the English: "ita ut in posterum aliquo modo jure Albinatûs fisco addici non possint." (Rhym., 'Fœd.,' tom. xvi. p. 650.) Letters-patent of Louis XIV., in 1669, confirmed in the parliament of Grenoble in 1674, exempted the Savoyards; and this exemption was confirmed by the Treaty of Utrecht in 1713. The inhabitants of the Catholic cantons of Switzerland were exempted by treaty in 1715. The particulars of numerous other conventional treaties are recorded in M. Gaschon's work, in the speech of the Duc de Levis already referred to, and in the 'Rapport' from the Marquis de Clermont Tonnerre to the French Chamber of Peers, printed in the 'Moniteur' for 1819, pp. 96–98.

Louis XV. granted exemptions, first to Denmark and Sweden; then, in the treaty called the 'Family Compact,' to Spain and Naples; to Austria, in 1766; to Bavaria, in 1768; to the noblesse of Franconia, Suabia, and the Upper and Lower Rhine, in 1769; to the Protestant cantons of Switzerland, in 1771; and to Holland, in 1773. In Louis XVI.'s reign, other treaties of the same kind were made with Saxony, Poland, Portugal, and the United States. The abolition of the Aubaine, as it related to Russia, was a distinct article of another treaty; and finally, by letters-patent, dated January 1787, its abolition was pronounced in favour of the subjects of Great Britain.

The National Assembly, by laws dated August 6, 1790, and April 13, 1791 (confirmed by a constitutional Act 3rd of September 1791), abolished the Droit d'Aubaine entirely. It was nevertheless re-established in 1804. ('Moniteur' for 1818, p. 551.) The Treaty of Paris, 30th of April, 1814, confirmed the exemptions from the Aubaine as far as they were acknowledged in existing treaties. The final abolition of the Droit d'Aubaine, as already mentioned, was proposed by the Duc de Levis, April 14, 1818, and passed into a law July 14, 1819, confirming the laws of 1790 and 1791. Foreigners can now hold lands in France by as firm a tenure as native subjects.

The Droit d'Aubaine was occasionally relaxed by the kings of France upon minor considerations. In the very early part of the 14th century, an exemption was obtained by the University of Paris for its students, as an encouragement to their increasing numbers. Charles V. granted the privilege in 1364 to such Castilian mariners as wished to trade with France. In 1366 he extended it to Italian merchants who traded to Nismes. The fairs of Champagne were encouraged in the same manner; and exemptions to traders were also granted by Charles VIII. and Louis XI. Francis I. granted the exemption to foreigners who served in his army; Henry IV. to those who drained the marshes, or worked in the tapestry-looms. Louis XIV. extended the exemption to the particular manufacturers who worked at Beauvais and the Gobelins; then to the glass-manufacturers who had come from Venice; in 1662 to the Dunkirkers, whose town he had acquired by purchase from England; and, lastly, to strangers settled at Marseille, that city having become the entrepôt of products from the Levant.

Ambassadors and persons in their suite were not subjected to the Droit d'Aubaine; nor did it affect persons accidentally passing through the country. Still, it was no small disgrace to the French law, that this barbarous custom should have so long remained among a people so highly civilised. Bouteiller, one of their own jurisprudents, who wrote as early as the 15th century, calls it "un Droit hayneux." ('Somme Rural,' fol., Lyon, 1500, fol. ii.)

That the Droit d'Aubaine existed in Italy, in the Papal States, in the 11th, 12th, and 13th centuries, seems established by Muratori, 'Antiq. Ital. Medii Ævi,' fol. Mediol. 1739, tom. ii. col. 14.

An extensive treatise on the Droit d'Aubaine has been already quoted in the works of Jean Bacquet, avocat de Roi en la Chambre de Thresor, fol., Paris, 1665. See also 'Memoires du Droit d'Aubaine,' at the end of M. Dupuy's 'Traitez touchant les Droits du Roy très Chrestien,' fol., Par., 1655; and the 'Coutumes du Balliage de Vitry en Perthois,' par Estienne Durand, fol., Châlons, 1722, p. 254. But the most comprehensive view of this law, in all its bearings, will be found in the 'Repertoire Universel et Raisonné de Jurisprudence,' par M. Merlin, 4to, Paris, 1827, tom. i., p. 523, art. 'Aubaine;' tom. vii., p. 416, art. 'Heritier.' The 'Moniteurs' of 1818 and 1819 contain abstracts of the discussions while the abolition was passing through the two chambers at Paris. See the latter year, pp. 314, 315, 509, 510, 728, 729. The chief passages in the former year have been already quoted.

AUCTION, a method employed for the sale of various descriptions of property. This practice originated with the Romans, who gave it the descriptive name of *auctio*, an increase, because the property was sold to him who would offer most for it. In more modern times, a different method of sale has been sometimes adopted, to which the name of auction is equally, although not so correctly, applied. This latter method, which is called a Dutch auction, thus indicating the local origin of the practice, consists in the public offer of property at a price beyond its value, and then gradually lowering or diminishing that price until some one among the company consents to become the purchaser.

The first-described mode of sale by auction was established by the Romans for the disposal of military spoils, and was conducted *sub hastâ*, that is under a spear, which was stuck into the ground upon the occasion. This expression was continued, and sales were declared to be conducted *sub hastâ* long after the spear was dispensed with. In the same manner, a company is in the present day invited to a 'sale by the candle,' or 'by the inch of candle,' with as little regard to actual practice. The origin of this expression arose from the employment of candles as the means of measuring time, it being declared that no one lot of goods should continue to be offered to the biddings of the company for a longer time than would suffice for the burning of one inch of candle; as soon as this rude kind of measure had wasted to that extent, the then highest bidder was declared to be the purchaser.

It is a common rule in law that no contract is binding without the assent of both parties. In sales by auction, the assent of the buyer is given by means of his bidding, while the assent of the seller is signified by the fall of a hammer; and until this declaration has been made, the intending purchaser is at liberty to withdraw his bidding.

It is a common practice for the owner of property offered for sale by auction to reserve to himself the privilege of bidding, and, as it is termed, buying in his goods, if the price offered by others should not suit his convenience. This practice was held by the civil law to be illegal, and even to partake of the nature of a fraud; and so lately as the time of Lord Mansfield, private biddings at auctions were so considered. In the present day, however, they are not only allowed by the law, but the legislature so far recognised the propriety of the practice, that in cases where the property had been bought in either by the proprietor or by his declared agent, who is in general the auctioneer, no auction duty was chargeable.

It has been laid down, that the buyer of goods at an auction cannot be held to the performance of his contract, in cases where he was the only *bonâ fide* bidder at the sale, and where *public* notice was not given of the intention of the owner of the goods to bid, even though his agent was authorised to bid only to a certain sum. This rule is intended to act as a protection to the public against the practice commonly resorted to by disreputable auctioneers, of employing persons to make mock biddings with the view of raising the price by their apparent competition: the persons thus employed are aptly called *puffers*. In many large towns, and more especially in London, many persons make a trade of holding auctions of inferior and ill-made goods; persons called *barkers* are generally placed by them at the door inviting strangers to enter, and puffers are always employed, who bid more for the articles than they are worth, and thus entice the unwary. Many ineffectual attempts have been made to put a stop to these practices.

The auctioneer is considered the agent of *both* parties, vendors and purchasers. In the language of the judges in a late case, "a bidder, by his silence when the hammer falls, confers an authority on the auctioneer to execute the contract on his behalf." He can therefore bind the parties by his signature according to the requisition of the Statute of Frauds, which renders it necessary in contracts of sale of 'lands or any interest in or concerning them,' and of goods above the value of 10*l*., that some 'note or memorandum should be signed by the parties or their agents lawfully authorised.' And such signature is *now* held sufficient even in an action brought by the auctioneer against the vendor in his own name. It has been doubted therefore, whether a bidder may not retract (in cases within the statute) at any time before the actual written entry. The auctioneer also stands in the situation of a stakeholder of the deposited part of the purchase-money, which he is not at liberty to part with till the sale has been carried into effect; and he cannot, at least after notice, discharge himself by paying over the amount to the vendor. From this peculiarity of his position it results that he is now not held liable for any interest on, or advantage which he may make from, the money in his hands. In this respect his situation differs from that of a mere agent, and also from that of one of the contracting parties (the vendor), from whom "interest is recoverable in the nature of damages for a breach of the original contract on the part of the vendor, by whose failure to make a good title the vendee has for a time lost the use of his money."—(Mr. Justice James Parke.) An auctioneer (like any other agent and trustee concerned in the sale of property) is forbidden to buy on his own account. And where he sells without disclosing the name of his principal, an action will lie against himself for damages on the breach of contract.

The conditions of sale constitute the terms of the bargain, and purchasers are bound to take notice of them. The late Lord Ellenborough said, that "a little more fairness on the part of auctioneers in framing particulars would avoid many inconveniences. There is always either a suppression of the fair description of the premises, or something stated which does not belong to them; and in favour of justice, considering how little knowledge the parties have of the thing sold, much more particularity and fairness might be expected." The conditions usually contain a provision that "any error or mis-statement shall not vitiate the sale, but that an allowance shall be made for it in the purchase-money." But this clause is held only to guard against unintentional errors, and not to compel a purchaser to complete the contract if he has been designedly misled.

The duties formerly levied upon goods and property sold by public auction, were repealed by the stat. 8 & 9 Vict. c. 15.

AUCTIONEER, a person whose profession or business it is to conduct sales by auction. It is his duty, previously to the commencement of every sale, to state the conditions under which the property is offered; to receive and to notify the respective biddings, and to declare the termination of the sale: for this purpose he commonly makes use of a hammer, upon the falling of which the biddings are closed.

The law holds that an auctioneer is authorised by the highest bidder or purchaser to sign for him the contract of sale; and that his writing down in his book the name of such purchaser, shall be sufficient to bind the latter to the purchase, provided no objection be made by him previous to such entry. The law also recognises the right of an auctioneer to act as the agent of persons wishing to purchase, who may intrust him to make biddings for them. The auctioneer thus being the agent of both parties, his signature of the buyer's name in the catalogue to which the conditions of sale are annexed, opposite to the lot purchased, together with the price paid, has been considered a sufficient note or memorandum in writing of the bargain within the Statute of Frauds; but where the conditions of sale are not annexed to the catalogue, nor expressly referred to by it, the signature of the buyer's name in the catalogue is not a compliance with the statute.

If an auctioneer declines or omits at the time of sale to disclose the name of his employer, he makes himself responsible toward the buyers for all matters in regard to which the responsibility would otherwise lie with the owner of the property sold. He is also responsible to his employer for any loss or damage that may be sustained through his carelessness or want of attention to the instructions given; and if by his gross negligence the sale becomes nugatory, he can recover no remuneration for his services from his employer. If he receives money as a deposit on the sale of an estate, and knowing that there is a defect in the title, pays that deposit over to his employer, he is answerable for the amount to the purchaser; and if he pay over the produce of a sale to his employer, after receiving notice that the goods of right belong to another, the real owner may recover the value from the auctioneer.

Every person acting as an auctioneer in the United Kingdom is required to take out a license, which must be renewed on the 5th of July in every year, and for this licence the charge of ten pounds is annually made. No licence, however, is required for the sale of goods under a distress for rent or tithes to a less amount than 20*l.*, or for the sale of goods by bailiffs under process of the county courts, or on sales by order of the Court of Chancery.

AUDIANS, or AUDEANS, a sect of heretics, so called from their founder Audius, or Audæus, who is said to have been a native of Mesopotamia, and who lived in the 4th century. Having begun, as usual with religious reformers, by attacking the manners of the clergy, and perhaps also the government of the church, he proceeded in this line till, persecuted by the orthodox, he separated from the church, with many followers, among whom were some bishops, by whom he was, on their own authority, ordained to the episcopal office himself. The sect appears to have arisen in Cœle-Syria. In his old age, on the accusation of some of the bishops that he induced the people to withdraw from the church, Audius was banished by the emperor to Scythia, about A.D. 338, where he occupied himself in introducing Christianity on his own principles, and is supposed to have died there some time previous to A.D. 372. Among various erroneous opinions and practices attributed to Audius and his followers are the celebration of Easter after the usage of the Jews, the admission of all descriptions of persons indiscriminately to the Lord's Supper, the doctrine of the eternity of fire, water, and darkness, and especially that of anthropomorphism, or the resemblance of the Deity to the human form, resting his belief on the expressions that God made man "in his own image," and those where the eyes, ears, &c., of God are mentioned. This last heresy in particular, which, as a Christian article of faith, appears to have originated with Audius, spread extensively. "The pilgrim Cassian," Gibbon writes, "who visited Egypt in the beginning of the 5th century, observes and laments the reign of anthromorphism among the monks, who were not conscious that they embraced the system of Epicurus." ('Dec. and F. of Rom. Emp.,' chap. 47, note.) But we have no account of the tenets of Audius, either from himself or any of his followers: we are dependent for all we know of him upon the statements of the orthodox theological writers of that and the next age, Athanasius, Augustine, Epiphanius, and Theodoret. He is admitted to have been a person of learning, and Epiphanius acknowledges that in his exile he exerted himself with great success in converting the barbarians, and says that he was chargeable with "defection and schism, but not with heresy," and that the Audians were remarkably strict in their morals.

AUDITOR, an officer or agent of the king, or of a private individual or corporation, who examines periodically the accounts of under-officers, tenants, stewards, or bailiffs, and reports the state of their accounts to his principal.

Auditors of the Imprest.—Ancient officers of the Exchequer, abolished in 1785.
